To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," either at the Manchester or the London Offices, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

Industries, VOLS. I. & II.

July to December, 1886, and January to June, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 10TH FEBRUARY, 1888.

THE MANUFACTURE OF CHLORINE.

IN the review we recently published of the chemical progress of last year, we briefly drew attention to some of the more important patents and processes which are being worked with the view of utilising calcium chloride waste liquors, and for preparing bleaching solutions by other methods than that which is now almost universally used, and which was perfected by the late Mr. Weldon. M. Hermite's electrolytic method for the preparation of chlorinated bleaching compounds, and M. Brin's patented solution of hydrochloric acid containing dissolved oxygen, have not as yet been introduced for a sufficient time to compete with bleaching powder and the older processes of manufacture. A method for the preparation of chlorine from hydrochloric acid without any waste chloride has been long looked for by chemists, and Mr. Weldon, for some years before his death, was experimenting with magnesium chloride and its oxychloride with this idea in view, and a patent entitled, "Improvements in obtaining, partly in the free state and partly as vapour of hydrochloric acid, the chlorine of the chloride of magnesium, of aqueous solutions of chloride of magnesium, or of mixed solutions of chloride of magnesium and chloride of sodium," was taken out in his name in 1884. M. Pechiney has recently succeeded in developing the process, and overcoming the mechanical and engineering obstacles which presented themselves, and has so far perfected the method that at Salindres, where his experimental works are situated, from 720 to 760 kilo. of chlorine have been made per day for several months past, and plant is now in process of erection for producing some 6000 kilo. of free chlorine per day.

The competition between the two great processes for the manufacture of soda is frequently affected by the introduction of improvements in the utilisation of waste products, or by the opening up of new fields for the use of the materials manufactured. The great depreciation in the value of ammonia salts has not only benefited the agriculturist, but has also been advantageous to the ammonia soda maker, and if Mond is successful in obtaining ammonia and chlorine from ammonium chloride by means of nickel oxide, or other metallic oxides combined with non-volatile acids, the ammonia-soda maker will be able to be entirely independent of the other industry. For the older process, efforts have been directed towards the recovery of the sulphur from alkali waste without the use of hydrochloric acid, and this has recently been effected with such success by Miller and Opl that, if cheaply carried out, it will considerably benefit the Leblanc manufacturers. Solvay's improved continuous furnace for the production of chlorine and hydrochloric acid by the decomposition of calcium chloride by silica, and Lake's experiments on the same reaction will, we hope, be found satisfactory when worked on a commercial scale, and result in a recovery of hydrochloric acid, and therefore be an alternative to the sulphur recovery method just alluded to. The Weldon-Pechiney process for the manufacture of chlorine from chloride of magnesium appears to have now passed from the experimental stage, and the mechanical difficulties which were met with in the erection of the plant at Salindres having been overcome, a considerable decrease in the amount of soda made by the Leblanc process is expected. The old Weldon recovery process and the use of manganese will thus give place to the direct preparation of chlorine from the natural chloride of magnesium of Stassfurt. At present, the raw material employed is hydrochloric acid, and the process is meant to be worked in common with the Leblanc soda method as a substitute for the present methods for the manufacture of chlorine and bleaching compounds. The first step consists in the formation of a solution of magnesium chloride, obtained by dissolving magnesia in the hydrochloric acid, which is then evaporated down until the solution has the strength corresponding to that expressed by the formula $MgCl_2 6(H_2O)$. An oxychloride of magnesium is then formed from this solution by the addition of the requisite quantity of magnesia in an apparatus of special construction. The mixture becomes very hard, forming pieces of varying size, which are subsequently broken, crushed, and then sifted. The dust is utilised either in the first operation, or is re-introduced into the apparatus when a fresh quantity of the oxychloride is being prepared. The broken lumps have next to be dried at a temperature below 300° before they are ready for the final decomposition. This drying is effected in a brick work tunnel through which a current of heated air passes, and the oxychloride in small trucks is drawn in the reverse direction. The decomposition is effected in a furnace which can be rapidly heated by a movable regenerative burner, and through which a current of air is drawn by means of an aspirator consisting of two cylindrical gasometers plunging alternately in a solution of chloride of calcium in which the chlorine gas is not soluble. Between the furnace and the aspirator, a tower for condensing the hydrochloric acid and a glass tube refrigerator are placed. The chlorine, after passing through the aspirators, is driven into milk of lime, which is slowly converted into chlorate and chloride of lime, from which potassium chlorate can be prepared in the ordinary way. About 40 per cent. of free chlorine is produced, and about 48 per cent. of chlorine as hydrochloric acid is condensed and utilised in the first operation. The amount of free chlorine, therefore, which is obtained is 78 per cent. of the chlorine used. Professor Dewar has calculated from these figures the relative price of 1 ton of chlorine prepared in England by this way, as compared with that produced by the old Weldon process, in which he shows that there is a saving of £5. 12s. per ton effected by the new method. At Stassfurt, where chloride of magnesium as a natural product has practically no value, a ton of chlorine should be produced at a cost of £5, or £2. 9s. cheaper than in England, or about £8 cheaper than chlorine prepared by the old Weldon process. If the ammonium chloride from the ammonia soda process is converted into magnesium chloride by means of magnesia, or the calcium chloride be decomposed by carbonic acid in presence of magnesia, the process can be worked in conjunction with the ammonia soda manufacture. The chief expense of the new process appears to be for the fuel consumed, but if the experiments which are now being carried out prove successful, a considerable diminution in the expenditure will be effected. The quantity of chlorine produced in the last operation depends on the temperature of the furnaces, and by a slight modification of the present

Digitized by Google

plant M. Boulouvard, the engineer at the works in France, hopes to be able to obtain hotter furnaces, and thus render the decomposition more complete.

Mr. Muspratt, in his presidential address to the Society of Chemical Industry at Liverpool, in 1886, pointed out that if magnesium chloride be substituted for salt as a source of chlorine, the natural seat for the preparation of chlorine compounds will be Stassfurt, and Professor Dewar, the president for this year, is of the same opinion. If Stassfurt magnesium chloride is used on any large scale for this purpose, considerable quantities of magnesia will accumulate, which may be readily converted into a useful and cheap cement. We hear that M. Hermite's process for electrolytic bleaching is now being tried on a large scale at Belfast, and in this process either calcium or magnesium chloride can be used for preparing the bleaching compounds. There will not be an accumulation of magnesia if this method be generally employed, unless the bleachers and dyers using the process consider it to their advantage to save their waste liquors. Considerable quantities of magnesium chloride could be, therefore, utilised by either or both of these new processes for the manufacture of chlorine, and with a demand for this salt at Stassfurt, it may then be worth while to recover the bromine which is at present lost by the present method of running the mother-liquor of the Stassfurt salts into the river. We must not forget that there have been recently several other methods proposed for bleaching on a large scale, and hydrogen peroxide appears to be capable of a much extended use. It may be that M. Brin's oxygenated hydrochloric acid will be found to be a cheaper bleaching compound than bleaching powder itself, and that the alkali manufacturers will then be content with the preparation of hydrochloric acid alone. Extended trials of these and other new processes in the same direction can alone decide which can be economially worked on a commercial scale; but we are inclined to believe in the future success of the Weldon-Pechiney process. The plant employed by M. Pechiney is complicated and expensive, but the engineering difficulties have been satisfactorily overcome, and although it may be unwise to predict, yet it would seem that we are on the eve of a new era in the manufacture of bleaching compounds from chlorine, and considerable alterations and modifications in the alkali trade may be consequently expected.

OUR BIG GUNS.

The bursting of a 10-inch gun while under proof at Woolwich again directs public attention to a subject which, though of vital national importance, has not yet received adequate consideration. Whether we regard it from the point of view of our national defences, or merely as a matter affecting our industrial supremacy, it appears a question of the first magnitude. From the former standpoint, it presents itself thus: Are our big guns efficient weapons, to be relied upon under all conditions? From the latter, we see it in this form: Are our manufacturers capable of building guns equal to those constructed by our rivals? In each direction lies a wide field for inquiry. Into neither of these, however, do we purpose at present to enter. But the occurrence at Woolwich cannot be allowed to pass without an expression of misgiving and apprehension, and a demand for a full and searching inquiry. We have been apt to look with pride and satisfaction on the marvellous achievements of the makers of our modern artillery. And truly we find in them just occasion for self congratulation. A big gun of the latest design is a remarkable illustration of the progress of science. It embodies the results of discoveries in several domains of knowledge. Chemistry has shown us the way to other and more suitable forms of iron than those known to our immediate predecessors. A better acquaintance with the structure of matter has enabled us to obtain greater resistance from the materials at our disposal. The development of engineering skill has led to the improvement and the multiplication of the mechanical means necessary for dealing effectively with those materials, particularly when in heavy masses. And a more accurate knowledge of the nature and the behaviour of explosive agents has brought within our reach forms of gunpowder capable of generating its tremendous forces according to a pre-arranged design. Thus a big gun is a triumph of modern science, to which the iron manufacturer, the engineer, and the powder maker have each contributed a large share. But our just admiration for the outcome of the combined efforts of these several parties is modified by a lurking suspicion, aroused and maintained by the frequent repetition of such accidents as that which occurred on 27th January at Woolwich, that there is somewhere in all this something amiss. The suspicion gathers consistence on reflection, and we are tempted to ask: has not the maker of heavy guns, in his desire to produce weapons more and more powerful, overstepped the limits of his knowledge and means, and built up his ponderous and imposing structures without due regard to the various conditions to which they are subject? Doubtless a chorus of voices will answer, "No." But we have to deal with the stubborn fact that of late guns have burst with alarming frequency. For this there must be a sufficient cause; and where are we to seek the cause if not in the inherent weakness of the gun? The elaborate reports of the commissions appointed to investigate these accidents served, by obscuring the point at issue, and by flattering our self love, to appease for a time the spirit of discontent which had been aroused. But frequent repetition of the same accident has thrown discredit upon these reports, and given rise to more disquieting misgivings. It will be hard to gloss over in the same way the utter destruction of the 10-inch gun at Woolwich the other day. We may safely assume that the gun was tested at Elswick, where it was built, before it was given over to the purchasers. Its breakdown can therefore hardly be due to a defect in the manufacture. This view is confirmed by the fact that it stood several rounds at Woolwich, and finally burst in a manner which points to a more serious fault. In his struggle with the manufacturer of armour plates, the artillerist has been compelled to increase again and again his charges of powder, till now he uses quantities that would have been regarded as fabulous a quarter of a century ago. If the truth be that he has gone too far in this direction, having in his haste outrun the gun maker and the powder manufacturer, it is well that he should be forcibly reminded of his error by the voice of public opinion making itself fully heard by the ruling powers. We shall await with interest the result of the official inquiry which must be made into the causes of the recent accident. Meanwhile the distrust which tends to paralyse the courage of our gunners will go on increasing. The matter is of extreme gravity, and it must not be allowed to rest where it now is, or to be languidly investigated with a view to its being quietly shelved later on.

THE PROTECTION OF TRADE.

The address which Lord Brassey recently delivered before the London Chamber of Commerce has deservedly attracted much attention, not only on account of the importance of the subject which he treated, but also because of the unique and thorough manner in which he had studied it. As a member of both Houses of Parliament, and as a Lord of the Admiralty, he had investigated all the ordinary sources of information; but not content with that he had undertaken a voyage of 36,000 miles, in order that he might personally inspect the positions of our coaling stations, our ports of commerce, and our Colonial defences, all of which are absolutely necessary for the carrying on of our immense trade. The London Chamber of Commerce has done good service in directing the attention of the public and of the Government to matters of national importance; but of all these, the latest —that of the defences of the Empire and the protection of trade—really includes all that have preceded it, for if our trade be destroyed all discussion about details is of no avail. From the remarks of the President of the Chamber of Commerce, it was evident that efforts had been exerted to arrange that the meeting should have been held in the Mansion House, under the presidency of the Chief Magistrate of the City of London, but the civic mind had not grasped the importance of the subject; at any rate these efforts had been unsuccessful. This, however, was compensated to a certain extent by the company of merchants and of distinguished naval and military officers who attended the meeting at the Cannon-street Hotel to hear what Lord Brassey had to say.

Before entering on the consideration of Lord Brassey's proposals, and with no wish to minimise the importance of these, it may be as well to remark that when persons or nations devote themselves too much to the study of self defence in case of attack, they are very apt to drift into a state of mind which magnifies trifles, and leads to scares over every little difficulty which arises, and gradually increase their defences till they become an intolerable burden. To exemplify this, we have merely to turn to the Continent, where we find nations armed to the teeth, and the Bourses of Europe agitated over every trifling incident, simply because these nations have carried their preparations for self defence to an extreme. Lord Brassey's proposals are by no means of an alarmist nature, and need inflict no great burden on the British taxpayer; but before even these are carried out, we ought to insist on the great spending departments of the army and navy being thoroughly re-organised, or an increase of their work will only intensify their present muddle.

Lord Brassey commenced by saying that all questions relating to national defences should be taken by common consent out of the domain of political controversy, and that the steps deemed necessary to the security of the Empire and its commerce once considered and determined, ministers on both sides should be equally bound to obey the mandate of the nation. We consider it altogether out of place to discuss party questions in this journal; but we cannot allow such a remark to be made without questioning its wisdom, or the possibility of ever carrying out the idea involved in it; it would just be about as easy to manage the internal affairs of the country without reference to party as it would its defence from external aggression. It is only by full and free discussion both in and out of Parliament, that the voice of the country, as distinguished from that of the Government officials, can be made known, as the opinions of the heads of departments are the most untrustworthy guides possible in such matters. Lord Brassey insisted that the proper defence of our coaling stations is strictly a measure of economy, that fortifications wherever practicable are the cheapest and most effective defence, and that the most costly and least effective is the detention in port of our cruisers, which should be employed in holding the ocean highways and in blockading the ships of the enemy. Not only are fortifications an economy, in that they reduce largely the numbers required to hold a position, they are an economy in regard to the description of force which is necessary; for example, the strong works by which our naval arsenals at home are now defended have not involved the addition of a single soldier to the regular army, as for the manning of these defences we must rely chiefly on the volunteers. These views are likely to be agreed to by all if they are not pushed to extremes, but no one will suppose that it is possible to render all our ports impregnable, we must confine our attention to the most important, and trust to our fleet for the defence of the others. Lord Brassey of course recognises this, and in his lecture he passed by Gibraltar, Malta, and Aden without any references to their defences, because we have the assurance solemnly given, on the responsibility of the Government to the Royal Commission, and renewed to the Conference of the Colonial Representatives, that the defences of these great Imperial fortresses will be maintained on a level with modern requirements. We must confess, however, that after personal inspection of the works at these three places, we have doubts whether they do meet such requirements. Passing from Aden to India, Lord Brassey considered the requirements of the chief ports in that vast country, and from there he went to Singapore, which he describes as a noble centre of trade, created as if by the enchanter's wand, under the British flag—the accepted emblem for all uncivilised and half civilised races, of justice, order, security, and unrestricted freedom of commerce. From Singapore he proceeded by St. George's Sound to Australia, and he bears witness to the high state of efficiency of the Colonial Naval Reserves. Turning homeward from Australia by the northern coast of the great Continent, he touched at Thursday Island, Port Darwin, and Mauritius. From thence he passed to Cape Colony and various other stations in Africa. Our space will only allow us to give his summary of the requirements which he considers necessary to complete the great scheme of defence which is now in course of execution. They are as follow: (1) At Aden, dredging operations; (2) at Bombay, additional monitors and the organisation of crews for the harbour defence flotilla; (3) at King George's Sound, Thursday Island, and Port Darwin, armaments of sufficient power to deny the harbour and the coal supply to hostile cruisers; (4) at the Cape, additional heavy breech loading guns, and a light military railway some six miles in length; (5) at Colombo, Singapore, Mauritius, St. Helena, and Sierra Leone, a local artillery militia; (6) at Ascension, if retained as a naval establishment, some armament is necessary. We agree with Lord Brassey that this enumeration will scarcely alarm the most jealous guardian of the public purse, as a moderate expenditure, fairly apportioned and judiciously applied, would fill up the gaps in our armour to which he has directed attention. He pointed out, moreover, that the above proposals should be supplemented by taking advantage of the assistance of our mercantile marine for the protection of our commerce, and he congratulated the present Government for the statesmanlike decision which they have taken to give subsidies for the retention of certain selected ships for the service of the navy in case of war. He recommended that in all contracts for the ocean mail services conditions should be imposed which would secure that the ships to be employed, or at least a certain number of them, should be adapted by their high speed and

Digitized by Google

internal arrangements for conversion into cruisers, and that the officers and men should belong to the Royal Reserve.

In the discussion which followed, the views expressed by Lord Brassey were warmly supported. The Duke of Cambridge, while urging the necessity of being fully prepared, had no wish to be considered an alarmist, and urged steady systematic preparation; but he warned Lord Brassey that his demands, although moderate, would run up a much higher bill than he seemed to anticipate, and that difficulties would likely be raised by the Chancellor of the Exchequer. Admiral Sir J. Commerell on this point remarked that a Chancellor of the Exchequer should feel much prouder when he retired, or was turned out, by being able to say: "Owing to my efforts I have left the army and navy in a proper state of efficiency," than of saving a penny in the income tax. Lord Charles Beresford was of opinion that such matters should be settled on the advice of the experts belonging to the army and navy, subject, of course, to the control of Parliament. Mr. John Glover's remark that the time had now come when it should be laid down that private property at sea should be exempt from capture, is not likely to lead to much. It would certainly be a highly advantageous arrangement for Britain, but the other Powers are not likely to agree to a proposal which would take away their best chance of inflicting injury on this country in case they should ever find themselves at war with us. In the absence of any probability of such an arrangement we ought to calmly set about carrying out the suggestions which Lord Brassey has made.

Letters to the Editor.

A RECENT TRIP FROM LONDON TO NORTH CHINA.

To the Editor of "Industries."

Sir,—The following particulars of a trip to North China, which I made at the end of last year, will, I hope, prove of interest to your readers, and explain to some extent the progress which is being made in the Far East.

I left London on the 29th September last in the s.s. "Glenshiel," a fine new steamer of 3300 tons, and about 1800 i.h.p., built and engined by the London and Glasgow Engineering and Shipbuilding Company, and had every reason to be satisfied with the vessel selected for such a long voyage. Our first stoppage was at Port Said, and we saw in the distance a large dredger in course of erection, but I had no time to visit the works of the Suez Canal Company. During our passage through the Canal, I did not observe any material difference in its general aspect since I was there in 1877. We saw one large steamer pass at midnight, by aid of the electric light. This lighting arrangement I understand consists of a small dynamo driven by a vertical engine, and supplied by the Canal Company at a charge of £10. The effect as the steamer approaches is really grand, as the powerful light at the bow sheds a glorious halo over land and water, and makes everything around shine like molten silver.

After leaving Suez we pass the lights at Zafarawa, Ras Gharib, and Ashrafir, on the Egyptian coast. From Ras Gharib to Shadwan requires careful navigation, owing to the many rocks and shoals, especially in the lower part of the Gulf of Suez. From the Strait of Jubal, in a direct course down the Red Sea about 110 miles, we passed two small islands called the "Brothers," on one of which a light has been erected. About 100 miles farther on is a sunken coral shoal called the "Dœdalus," on which the P. & O. Company erected a light many years before the Suez Canal was opened. From this shoal to the Island of Perim, a distance of about 850 miles, there are no lights whatever, the course down mid-channel, as far as a group of islands off Musawa, being fairly clear. From here we had an intricate channel and no lights, with several islands in the direct course, on which lights might be placed with great advantage, such as "Jebel Teir," "Zebayir Islands," and on "Abu Ail" rock, the northernmost of the Hamish group. About midway between the "Zebayir" and "Abu Ail" rocks two steamers have recently been lost, having struck on hitherto unknown sunken rocks or reefs, the positions of which have not yet been ascertained. This now necessitates a deviation from the usual course, and the most careful navigation at night or in thick weather, owing to the want of lights. From "Abu Ail" in a direct line to Perim, the shoals off Mocha, on the Arabian coast, extend almost to the track taken by the steamers, and a light is much required here. From Mocha to the Island of Perim the course is pretty clear, and Perim is furnished with a good light, and also a Lloyd's signalling station. The Perim Coaling Company have erected a small engineering works and foundry, with appliances for executing repairs to a moderate extent to passing steamers, which must often prove a great boon, as there is no other available place for this purpose nearer than Bombay or Suez. At our next port of call, viz., Penang, we only remained from 6 p.m. till 1 a.m. next morning, and I had no opportunity of inspecting the tramway recently laid down there.

At Singapore I observed many improvements since my last visit ten years ago. A tramway has been laid down in the town and suburbs for seven or eight miles. It is worked by steam power, and carries both goods and passengers; but owing, I believe, to the introduction of jinrikishas (man power carriages) from Japan, numbers of which ply for hire in every street, at low fares, the tramway is not a success financially, and on one portion of the line passing Whampoa's Gardens, I found the working had been discontinued for want of sufficient traffic. The Tanjong Pagar and Metropolitan Dock Company's establishments were both fully employed on repairs to steamers, &c. Engineering work was also being carried out by several other firms. The Straits Ice Company turn out about five tons of splendid clear block ice per day, at a cost of about £4. 10s. per ton, their two works being under the management of Mr. Robert Park, who conducted us over them, and explained the different processes of the two plants of English and German machinery. Considerable alterations and improvements have been carried out in Singapore on the roads and bridges, under the superintendence of the municipal engineer, and I noticed several handsome little bridges erected at various points over creeks and ditches. I much regret that time would not allow me to inspect the progress of the new defences for this most important coaling station.

On arriving at Hong Kong we were moored to a jetty at Kowloon, on the opposite side of the bay from the town of Victoria. Since I was here in 1877, immense progress has been made. At that time where we were moored was a barren shore. Since then, large well built and handsome warehouses or go-downs have been built. Quays and jetties have been constructed, with well laid out lines of rails of about 2ft. gauge, with trucks to correspond, which are simply and strongly made, with steel wheels and axles. By this arrangement goods can be landed and warehoused in the speediest and most economical manner, with much less wear and tear than formerly. The workshops at Kowloon of the Hong Kong and Whampou Dock Company have been entirely re-arranged, and tools of the largest and most modern type laid down, capable of turning out any class of marine and general engineering work. The new dock, which, when finished, will take in our largest ironclads, is also making steady progress.

When *en route* to Japan in 1876, I had the pleasure to meet, in Chicago, Mr. A. Findlay Smith, of Hong Kong, and during our journey between there and Yokohama he spoke of a tramway which he thought could be made to the Peak on the mountain behind the city of Victoria, and on meeting him again after the lapse of eleven years, I was both surprised and delighted to find his former crude ideas not only matured, but worked out; and I believe the Hong Kong High Level Tramway will be in operation before this is in print. As probably few of your readers have been in Hong Kong, one of the most beautiful places in the Far East, it may not be out of place to state that owing to the hills rising abruptly behind the city, it has been hitherto cramped in its building extensions. The Government have made a series of splendid roads on the sides of the mountain leading to the Peak, and planted this once barren rock with many thousands of fir and other trees, under the superintendence of Mr. Ford, a gentleman highly skilled in arboriculture. This has enabled the wealthier residents to build houses on these terraces above the city, where they can enjoy the pure bracing air and lovely scenery. The completion of the high level tramway will not only enhance the value of the Government land, but render the whole mountain side available for building purposes, and make it a grand sanitarium within the reach of nearly all classes of the community. The tramway has been laid down from St. John's Place, Garden Road, to Victoria Gap, a length of 4690ft. The height of the upper above the lower terminus is 1207ft. The easiest gradient is 1 in 25, and the steepest 1 in 2. On the lower part of the line two steel rails of 35lb. per yard are laid, of 5ft. gauge, and forming a single line; and on the upper half three rails are laid, forming a double line. Half way is a cross siding with four rails about 130ft. long in the clear, having switches at the lower end. Steel sleepers, weighing 24lb. per yard, are bedded in lime concrete 6in. thick. The bridges, eleven in number, are constructed of wrought iron girders. The carriages are mounted on bogies, and carry about forty passengers, and when loaded weigh between five and six tons. The motive power consists of two pairs of compound horizontal engines with multitubular boilers, each 40 n.h.p., and erected at the upper terminus. Motion is communicated to the carriages by means of a flexible plough steel cable, $3\frac{5}{8}$in. in circumference, passing over grooved winding drums, and tested to a breaking strain of 54 tons. At each end of the cable the carriages are attached, so that while one train ascends the corresponding train descends, passing each other half way. The cable will haul up at one time one hundred and twenty passengers, equal to a maximum working load of $7\frac{1}{2}$ tons tensile strain. Cable guide pulleys are placed along the line at distances varying from three to eight yards. Each carriage is fitted with two steel clip brakes, arranged to grasp the centre brake rail, and to act at all times, unless held out of action by the brakesman; also with a pair of steel clip brakes to work on the 35lb. rails. The centre brake rail is of steel, weighing 66lb. per yard, and is laid between the ordinary rails. It is jointed and fixed to the sleepers with steel bolts and clamps. Starting from the lower terminus, the line proceeds for about 400ft. in a south-west direction, when a slight curve, of 500ft. radius, alters the course to south-south-west, which is continued until an altitude of about 900ft. is reached, where a curve of 300ft. radius changes the direction to west, after which it is almost straight to the upper terminus. The speed will be about six miles per hour, and reduced to four miles at the points and crossings. There will be several stations, and a single journey, without stoppages, will be made in ten minutes. The brakesman can at any time electrically signal the engine driver at the top to start or stop the train, and telephonic communication exists between the termini. The inhabitants of Hong Kong are much indebted to Mr. A. F. Smith and his co-directors for the energy and perseverance with which this unique undertaking has been carried out, and I earnestly hope that it will more than realise the expectations of all concerned, both practically and financially. Mr. J. F. Boulton, Assoc.M.Inst.C.E., is the engineer in charge, and Mr. James Anderson the manager.

Another improvement of great importance to Hong Kong is, I understand, being promoted by Mr. Chater. It is the bold one of extending the bund or quay seaward a distance of 250ft. This reclamation scheme would provide new sites for a splendid range of buildings on a fresh frontage to the bay, and a commodious bund, combining all the latest improvements for loading and discharging vessels. It would also provide for a splendid new street on the site of the present bund. I hope it will in due time be carried out, so as to meet the yearly increasing trade of Hong Kong.

On approaching Shanghai we had a good view of the commodious new dock, recently opened by Messrs. Boyd & Co., engineers; but as I left the "Glenshiel" and sailed again in a few hours for Tientsin I had no opportunity of inspecting this or the new water works, but hope to do so next spring. Leaving Shanghai by the "Kowshing," a fine steamer specially built for the Chinese coasting trade by the Barrow Shipbuilding Company, with great breadth of beam, moderate draught, and most commodious accommodation for first class passengers, and a large number of second class Chinese passengers, we arrived in three days outside the bar at Taku, the entrance to the river Peiho, and after a few hours' detention entered the Peiho, obtaining a good view of the forts guarding the entrance. On the south bank we passed the Imperial Naval Dockyard, and on the north side, further on, we saw a large number of men constructing the earth works for the new railway from the Kaiping Coal Mines and Taku to Tientsin. Since then several steamers have arrived with locomotives and other plant; the work will therefore go on uninterruptedly during the winter.

On nearing Tientsin, a distance of about 57 miles by the river from Taku, we saw a large balloon, partly inflated, in the grounds of the Military College, on the north side of the river, and on the south or Tientsin side, an immense building in progress of construction, which, we understand, when finished, will be a new Military and Naval Anglo-Chinese College, under the charge of European professors. At Tientsin were numerous piles of merchandise all along the bund, and crowds of coolies loading and unloading steamers and other craft, forming altogether a busy scene, far beyond my anticipations.

Yours, &c.

Allan C. Wylie.

Tientsin, North China, 10th December, 1887.

THE BOILER REGISTRY AND INSPECTION BILL.

To the Editor of "Industries."

Sir,—The letter from your correspondent "Boiler" was of special interest to me, as he opens up a subject which I was afraid would be overlooked by steam users generally until some fine morning they found from their morning paper that the Boiler Registry and Inspection Bill, with all its vexatious interference, had become the law of the land. I consider, sir, that no more unfortunate or inopportune time could possibly have been selected than the present for the introduction of a Bill of this nature. When trade is still languishing, and nothing but complaints are heard on every side, when some markets are closing, when foreign competition is so keen and vigorous that in some branches it is already pushing us from our stools, then Board of Trade officialdom endeavours to saddle the already failing horse with another burden, and to hamper its action by restrictive rules and regulations. Will the manufacturers and steam users of the United Kingdom sleep idly on, and allow another great blow at their interests to be struck, without even a protest? If they once allow the foot of a Board of Trade inspector of steam boilers within their premises, they will then have ample cause to regret their present supineness, and when writhing under the losses of time and money which will result, vainly wish they had not allowed the golden moments to pass when resistance would have been effectual. If the Bill to which I refer is allowed to pass, the steam users of this country will be saddled with a most oppressive enactment, involving great trouble, loss of time, and expense not only to be incurred in paying the staff necessitated by the Act, but also the expenses of carrying out the Act, the whole of which by the provisions of the Bill are arranged to fall upon them. In addition to this there will be enormous expense involved in altering their steam power to the absurd whims of the Board of Trade engineers, involving the removal of all Green's, Lowcock's, Twibill's, and other cast iron economisers, as foreshadowed by Messrs. Traill and Woodthorpe in their famous report No. 242, and the removal of all boilers with a factor of safety of less than 5, which would include about seven-eighths of all the boilers in use.

Assuming the total number of boilers in the kingdom to be 150,000, the carrying out of that rule alone would result in the replacement of upwards of 133,300 boilers, averaging an expense in so doing of £300 per boiler, the total cost of which would be £39,990,000. Of the value of the Board of Trade factor of 5, let the following facts speak: In the year 1869 a firm not far from this city laid down and set to work a boiler of the Lancashire type, 28ft. in length and 7ft. diam., single riveted, punched holes, plates $\frac{1}{4}\frac{3}{2}$in. thick, of ordinary Staffordshire make, and have continued to work it during the whole of the nearly nineteen years at 67lb. per square inch; that is to say, with a factor of 2·6, or about half the Board of Trade requirement. Taking the cost of replacing existing economisers at £6,000,000, as estimated by "Boiler," in his letter, a grand total of £45,990,000 is reached. Taking this amount as the capital sum required to be spent to bring steam users up to the Board of Trade requirements, and the cost of working the Act at, say, £500,000 per annum, I think it may fairly be admitted that the present time is not the one suited for such an experiment.

Sufficient grounds for the passing of such a Bill as the Boiler Registry and Inspection Act do not appear to exist. Can any good and sufficient reasons be brought forward to justify the infliction of such a tremendous imposition of penalty and loss upon the steam users of this country? The facts appear to show conclusively that, on the contrary, no further legislation is at present required, and nothing beyond a wise use of the means now in hand is necessary.

Sir Thomas Gray, assistant secretary to the Board of Trade, in his fifth annual report upon the working of the Boiler Explosions Act, 1882, gives the total number of explosions for the year 1886-87 as 37, and the deaths caused thereby as 24. These figures include the explosion of ammonia stills, kiers, steam pipes, drying cylinders, kitchen boilers (excluded from the provisions of the new Boiler Registry and Inspection Bill), &c.; in fact, every accident that could be included having the faintest resemblance to an explosion, from the improper giving way of a fusible plug, to the most serious explosion, involving great loss of life, the disposition of the Board of Trade inspectors being to multiply examples, and thereby to exalt their office. A striking instance of this disposition may be quoted from Report No. 242, in which Mr. Thomas W. Traill, the Engineer Surveyor-in-Chief says: "*Although the number of economiser explosions reported appears to be not very great, perhaps if all the failures of tubes were reported under the Boiler Explosions Act, as they should be, there would be more failures to record.*" If I had not the official report before me as I write, I should think this was merely the expression of a disappointed rival economiser

Digitized by Google

maker, and not that of a judicial officer receiving a Government salary. However, perhaps he has an "exquisite reason" for it. Still, it will be observed, even with this disposition to exaggerate, it has not been possible to gather together more than 37 explosions, real and so-called, with a death roll of 24. During the previous four years of 1882-1886, that is to say, since the passing of the Boiler Explosions Act, 1882, 133 explosions, causing 90 deaths, took place, or an annual average of 33·2 explosions and 22·5 deaths.

From figures published by one of the boiler insurance companies, it has been clearly shown that taking the experience of the previous twelve to sixteen years into comparison, this represents a decline in the number of explosions of no less than 42·2 per cent., and in that of the number of deaths of 67·6 per cent. If the action of the Boiler Explosions Act, 1882, has been sufficient to produce such very satisfactory results in so short a time, simply from the dread of a preliminary inquiry, and without once putting in force its penal clauses, what would be the effect if, in the case of a proved instance of carelessness or of recklessness, a formal inquiry were held, and all the costs and penalties laid upon the culprit? In addition to this penalty, the Board of Trade are empowered by the present Act of 1882 to publish the circumstances as they think fit, and the unenviable notoriety thereby accruing would be, in my opinion, an ample deterrent. It is clear also that the decision of the Board of Trade would greatly affect the decision of any case under the Employers' Liability Act which might be pending arising from the explosion and its results. Nothing more requires to be done beyond simply setting the powers already held by the Executive in action, and it certainly would be most undesirable to erect and set to work enormous and cumbrous machinery of such an expensive character to do the work before we have tried the tools we already possess. Let the Act of 1882 have a fair trial, say of another four years, and let all its provisions be carefully and judiciously enforced; we shall then see that there is no need for further legislation on the subject. Explosions will have fallen to the few which even a Board of Trade inspector would admit were entirely accidental, and which could not by the exercise of any engineering skill be prevented.

When these views are generally known, I feel sure that their force will be seen, felt, and acted upon. The Oldham Chamber of Commerce, I notice from a local journal, has already passed the following resolution: "That this Association is strongly opposed to the Boiler Registry and Inspection Bill, 1887 (introduced into the House of Lords by the President of the Board of Trade last session), which it considers unnecessary, as shown by the rapid diminution of accidents which have taken place during the past few years, and as only likely to further embarrass trades already sufficiently harassed by Parliamentary enactments; and would call attention to the Boiler Explosions Act, 1882, the powers under which already conferred upon the Board of Trade, IF PUT IN FORCE, are amply sufficient to act as a safeguard against accidents, and as a deterrent to carelessness on the part of owners of boilers."

This example is to be commended to the notice of other Chambers of Commerce, and I certainly hope that a strong and irresistible force of opinion will be formed, so that the promoters of the Boiler Registry and Inspection Bill may be held in check, and prevented from adding this additional bar to trade and industrial progress.

Yours, &c.,

ECONOMISER.

Manchester, 6th February, 1888.

THE INVESTMENT OF CAPITAL IN SPAIN.

To the Editor of "Industries."

SIR,—I see from your London letter of the 26th January that a company has been registered under the title of the Andalusia Iron, Coal, and Steel Works Company, with a capital of £1,200,000. This seems to be a very large sum to employ in coal raising and metallurgical pursuits in Andalusia; but still the thing is feasible if it is intended to manufacture railway material and to build ships, as well as to export ore and pig, and furnish a coal supply to Gibraltar with the company's own steamers. But if the business is not developed to that extent, the home market is too small for the employment of such a large capital. I suppose that the coal fields which it is proposed to develop are in the Belmez and Espiel district; but their situation would not allow of their ever becoming the centre of a metallurgical industry on a large scale, owing to the scarcity of water. Again, if the iron mines which it is proposed to develop are the Pedroso or Fuente del Areo mines, the ores cannot be smelted on the spot, as there is not sufficient water even for the boilers, a small works in the district having been unable to obtain water during three months of the year for a 40 h.p. condensing engine.

In forming a large establishment in Andalusia on the lines of Creusot, Cockerill, or Krupp, it would be necessary to secure a site in the neighbourhood of the Guadalquiver, the question of a good supply of water being of the utmost importance. This would, however, cause a great part of the advantage of cheap ores and coal to be lost, since both would have to be transported a considerable distance. There would therefore be some difficulty in establishing an export trade, and for the inland market a works turning out 100,000 tons of pig iron per annum appears rather too large, even if the establishment goes in for making rails, locomotives, waggons, shipbuilding, and other branches of large engineering.

Your MADRID CORRESPONDENT.

Madrid, 2nd February, 1888.

TRANSMISSION OF POWER.

To the Editor of "Industries."

SIR,—Much has already appeared in your journal about the electric transmission of power. As *Industries* is very largely read, not only by electrical engineers, but by all classes who have anything to do with power transmission, I venture to add another letter. First, as to efficiency. The efficiency of transmission depends on a great many factors, such as cost of machinery, speed, power transmitted, &c. For instance, a large power, such as 500 h.p., can be transmitted a mile with a gross efficiency of 85 per cent. without any difficulty. If the dynamos and motors have to go at slow speeds, of course the efficiency is lower. For small powers, such as 50 h.p., with reasonable dynamo speeds, 75 to 80 per cent. is obtainable over a mile or so. Engineers do not seem to realise that electrical transmission is not a sort of guess work. A plant can be calculated within 1 per cent. or so without any difficulty, and the exact efficiency and waste is always known beforehand. In "Erg's" very able letter he points out that English makers try to make their machines too light. There may be some truth in this in some cases, but none of the large manufacturers countenance these practices. Many of the extraordinary slow speed machines, or light machines, are made to please customers with theories of their own on such subjects. If an engineer asks for a light dynamo or motor, or one to run at a slow speed, one naturally expostulates at first; but finding that of no avail, makes it rather than let the order pass. Engineers also often seem to think motors are in some way a special kind of machine that is not yet fully understood by dynamo makers generally. In fact the old fallacy that a good dynamo is a bad motor is not yet quite rooted out. With regard to Mr. Preece's letter, I am sorry to disagree with such an authority, but cannot see any inaccuracy in the calculations of the efficiency of the Oerlikon transmission. The only fault is the crude method of measurement of the powers supplied and received. It is rather barbarous to use brakes or transmission dynamometers for testing, when the electrical methods are capable of such perfect accuracy with infinitely less trouble. Perhaps, however, many engineers would not be satisfied with anything but brake tests, to which they are more accustomed. Electrical transmission has another advantage which must not be overlooked. A motor is always capable of giving an enormous output for a short time when required. For instance, a motor made for say 10 h.p. will give 30 or 40 h.p. for a short time if required. This property is especially important in locomotive work. Another advantage an electric motor has is its constancy of speed. When required a motor can be made to run with a varying load at even more nearly constant speed than the engine that drives the generator.

Yours, &c.,

JAMES SWINBURNE.

2nd February, 1888.

ON Saturday, the 4th inst., the Corporation of Stettin decided to purchase three ice breaking steamers, and a sum of £20,000 has been set aside for this purpose.

GREAT NORTHERN TELEGRAPH COMPANY.—Traffic returns: Receipts in January, 1888, £21,400; corresponding month, 1887, £20,400; corresponding month, 1886, £19,880.

EXHIBITION OF METEOROLOGICAL INSTRUMENTS.—The Royal Meteorological Society intend to hold an exhibition of apparatus connected with atmospheric electricity, including lightning conductors, photographs of lightning, and objects damaged by lightning, at the Institution of Civil Engineers, from 20th March to 23rd March. The exhibition committee is anxious to obtain as large a collection as possible of such apparatus, and will also exhibit any new meteorological instruments or apparatus invented or first constructed since last March.

SOCIETY OF CHEMICAL INDUSTRY.—At the February meeting of the Manchester Section Mr. Rowland Williams, F.I.C., F.C.S., read a paper on the "Adulteration of Tallow with Cotton Seed Oil," in which he said that during the past year he had examined a large number of samples specially for this adulterant, and had found it to be present in one or two cases. Owing to the comparatively low price of cotton seed oil there is plenty of scope for profitable adulteration by dishonest merchants. The author stated that it was possible to add as much as 40 per cent. of cotton seed oil to tallow without the mixture differing appreciably in general appearance from ordinary tallow. In fact, the only means of detecting the fraud is by chemical analysis. A series of mixtures of tallow and cotton seed oil, containing from 5 to 40 per cent. of the latter, was prepared in Mr. Williams' laboratory. The melting points and saponification equivalents of these were nearly the same as those of pure tallow. The author found, however, by determining the iodine absorptions of the various mixtures, that it is easy to detect 5 per cent. of cotton seed oil, which is the smallest proportion likely to be introduced into tallow. Each percentage of iodine absorbed in excess of that required by genuine tallow indicates adulteration with about 1½ per cent. of cotton seed oil. Mr. Williams therefore recommends, in addition to the usual tests, the application of Hübl's reagent in the analysis of tallow, as being the most certain means of detecting adulteration.

THE COAL FIELDS OF SOUTH AFRICA.—In a paper entitled "Contributions to the Physical Geology of Cape Colony," read by Professor A. H. Green at the meeting of the Geological Society, on January 25th, reference was made to the coal fields of South Africa. The coal seams occur in the Moltene beds, which overlie the well known Karoo beds, and are overlain by the Red beds and Cave sandstone. Their formation Professor Green considered as raising questions of much interest, as, unlike most coal seams, he believed them to have been subaqueous in origin. This opinion he based mainly on the absence of the underclay that forms so well known a feature in our English coal seams. The author maintained that the structure of the coal further confirmed this conclusion; the coal consists of excessively thin layers of bituminous matter separated by mud films; on examining the ash left by the combustion of the coal before the blow pipe, it is found to consist of minute lenticular grains of sand or silicious matter. Professor Green suggested that as the sand slowly sank through the waters of the lake in which the coal was deposited, it became coated with the decayed vegetable matter with which the water was charged. The coal field yields two principal varieties of coal, one free burning and the other slow burning; but even the best quality contains 25 per cent. of ash. The coal bearing strata have a very irregular dip, and hence one must accept with great caution the sanguine expectations of speculators. In conclusion, Professor Green said that he did not think it likely that the coal field would ever prove of great commercial importance.

SHIPBUILDING NOTES.

Messrs. Workman, Clark, & Co., Limited, Belfast, launched on the 28th January, a handsome steel screw steamer named "Macgregor," for Messrs. Colvils, Lowden, & Co., Glasgow. She is the sixth vessel built by them for this firm. She has been specially designed for the American fruit trade, to carry bananas from Belize to New York, and is expected to be one of the fastest boats on that station. The dimensions are: Length, 215ft.; breadth, 32ft.; depth to floors, 21ft. 3in. She is of the awning deck type, and has a cellular double bottom both fore and aft. There is accommodation for thirty passengers in a bridge house amidships. She will be classed at Lloyds' 100 A1 Awning Deck. After the launch she was towed to Glasgow to have her engines and boilers put in by Messrs. Muir & Houston.

On Monday last the new screw steamer "Nicholas" went to sea for her trial trip. The vessel is 212ft. by 30ft., and 14ft. draught, and has been built by Messrs. Wood, Skinner, and Co., Bill Quay, Newcastle, for the Russian Company of Land and Sea Conveyance of St. Petersburg and Odessa. She is a sister ship to the "Platon," recently built by the same builders for the same company. The engines have been constructed by the North-Eastern Marine Engineering Company, Wallsend, and they are the fourth set built by them for the same owners. They are on the three crank triple expansion type, with cylinders 17in., 28in., and 46in., by 30in. stroke, and include all the most modern improvements. During the trial the engines ran at 102 revolutions without difficulty, and great satisfaction was expressed with the machinery and the speed obtained, viz., 10¼ knots, being half a knot in excess of the guaranteed speed.

There was launched recently from the shipbuilding yard of Messrs. R. &. W. Hawthorn, Leslie, & Co., Limited, Hebburn, Newcastle, the first of two steel twin screw steamers, now being built by them for the mail and passenger service of the Chinese Government. The dimensions of the vessels are: Length, 260ft.; breadth, 34ft.; depth, 19ft. The vessel is made to the highest class at Lloyd's, with deck house for the accommodation of passengers from the after end of forecastle to the stern. Over this house is an awning deck extending the full width of the ship, and of the same length as the house. Forward of the engine and boiler space, in the large deck house before mentioned, is a handsome saloon for first class European passengers, together with the necessary state rooms, lavatory arrangements, &c. This saloon will be handsomely fitted in carved oak framing and ash panels. The vessel throughout will be lighted by the electric light, including mast head, side lights, cargo lamps, &c. This is being supplied by the Woodside Electric Light Company, of Glasgow. The vessel has steam windlass and steam winches by Messrs. Clarke, Chapman, Parsons, & Co., Gateshead, and also steam steering gear. The vessel will be driven by two sets of triple expansion engines, having all the latest improvements, including Marshall's valve gear. There will be two multitubular double ended boilers, which will be supplied with forced draught, and worked at a pressure of 160lb.

Messrs. Armstrong, Mitchell, & Co. launched from their Low Walker yard, near Newcastle, on the 3rd inst., a large vessel named the "Paula," which is intended for the oil carrying trade, and is now being fitted with engines by the Wallsend Slipway Engineering Company.

On Wednesday last the new steel steamer "Cabo San Antonio" made a very satisfactory full speed and progressive trial trip, after the vessel's return from Stockton-on-Tees, where the engines and boilers have been fitted by Messrs. Blair & Co., Limited. This vessel has been built by Messrs. J. L. Thompson & Sons, North Sands, Sunderland, to the order of Messrs. Ybarra & Co., Seville.

Reviews.

A PRACTICAL TREATISE ON BRIDGE CONSTRUCTION. By T. Claxton Fidler, M.Inst.C.E. London: CHARLES GRIFFEN & Co. 1887.

This book is a model of what an engineering treatise ought to be, and fulfils all the requirements which we have often pointed out ought to be met by text books intended for men engaged in practical work, as well as of great use to the more advanced students in colleges. Its author, who is well known, not only for the theoretical knowledge he possesses of bridge building, but also for his practical experience in actual construction, has made an excellent blend of theory and practice, not so much of the former to repel all except the mathematicians, and just sufficient of the latter to meet the requirements of intelligent engineers, who would of course supplement that part of it by the results of their own observations and experience. Moreover, the whole work is written in a fresh and vigorous style, and presents a considerable amount of useful information, which will be of interest to numbers of general readers; for, as the author explains, his object has been not only to describe the modern practice of bridge construction, but also to set forth in the simplest language the mechanical principles and experimental facts on which it is based. The necessity for such a work as that by Mr. Fidler has arisen from

Digitized by Google

the many important changes which the art of bridge construction has undergone within the past few years. Engineers have been called upon to construct bridges of unprecedented magnitude, whose design and execution have presented a number of new problems, or have invested old ones with an interest which they did not before possess. And further, as our author points out, new problems of interest have arisen in connection with the introduction of steel, the adoption of new forms of construction, and the employment of new methods of research; while the constant accumulation of experimental facts has in the meantime added largely to our stock of practical knowledge in regard to such subjects as the strength of materials and the effects of wind pressure. In order to make the book useful not only to engineers and draughtsmen who may be engaged in the work of bridge calculations and bridge construction, but also to students, the author has devoted the earlier parts of the work to a simple demonstration of those mechanical principles which must of necessity form the beginning of any study of the subject, and which are more fully developed and applied in the later portions of the book. He has employed to a considerable extent a geometrical method of investigation, not as a mere translation from the language of algebra, but as a parallel and independent method which is capable in itself of affording positive demonstrations, and of yielding direct solutions for most of the problems that arise in bridge construction. He has, however, kept his geometry within moderate bounds. When an enthusiastic specialist takes up a subject he generally runs it to death, and his work is of little use to the practical engineer. Within the past few years geometrical methods have been much developed; but many of them are little more than curiosities and examples of misplaced ingenuity, and we are glad to observe that Mr. Fidler has restrained himself in this matter. The earlier parts of the work contain a detailed application of the combined geometrical and algebraical methods to the determination of those bending stresses which take effect in all bridges, and to the classification of bridges. The subject of the strength of materials, and its application to the design and construction of tension members and compression members, the strength of columns and struts, and a comparison of the results of those with those of the most recent experiments, is then taken up, and the facts, rules, and principles involved are collated and applied to the practical work of designing bridges of various types of construction; and in every case the calculations are so arranged and tabulated that the sectional areas of the various members can be readily determined by the older methods, or by either of the newer methods for fixing the working stress. The latter part of the work is taken up with the more practical aspects of the subject, and the methods of designing various types of parallel and bowstring girders, bow and chain bridges, arched ribs, suspension bridges, and cantilever bridges, each of which is treated in a highly satisfactory manner, and well worthy of the attention both of the engineer and the student. The concluding chapter of the work is devoted to the question of wind pressure, a subject whose importance has only recently been realised, and which a short time ago was discussed in the correspondence columns of this journal. Throughout the work there is a considerable amount of useful advice on miscellaneous subjects. For instance, on the subject of theory and practice, the author says: "In the practice of iron bridge construction, and still more in its future development, theory must always be regarded as an indispensable guide, if only for the reason that there is always a point beyond which experiment will not carry us. At the present moment the trustworthiness of theory is so fully recognised that no one will think of determining the proportions and details of an iron bridge without reference to theoretical calculations, or by the mere exercise of that indefinable quality which is known as the 'judgment' of practical men. The time has, therefore, gone by when it is necessary to protest against that unreasoning objection to theory which can only have arisen from a mistaken notion as to the real meaning of the word. In fact theory, in its broadest and truest sense, is universally employed in all mechanical designs and operations; and the so-called 'practical' man who will have nothing to do with it is unconsciously in the position of the bourgeois in Molière's comedy, who would not believe that he had been all his lifetime speaking and writing *in prose*." Then again, speaking of bridge construction, the author says: "Economy in bridge construction is something very different from mere saving of cost, and has nothing in common with that sort of economy which consists in reducing expenditure at a corresponding sacrifice of efficiency, or strength, or fitness. On the contrary, it insures the highest possible efficiency by making the best use of the given material, and without it the safe construction of very huge bridges would be impossible." On the whole, we have very much pleasure in commending Mr. Fidler's book, not only for its theory and account of practice, but also for the sound common sense opinions with which it abounds.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

At yesterday's meeting of this Society the paper read was on "Alternate Current Transformers, with special reference to the best proportion between Iron and Copper," by Mr. Gisbert Kapp. Reduced to its simplest form, a transformer consists of a magnetic circuit interlacing with an electric circuit, very much like two links in an ordinary chain, as represented in Fig. 1. In this

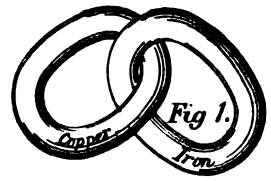

Fig 1.

case the co-efficient of mutual induction between the two circuits is a maximum, and is equal to the square root of the product of the two co-efficients of self induction. In all modern transformers the condition for maximum mutual induction is fulfilled, the iron core exhibiting no external magnetism, and the different types of transformers now in the market are only distinguished by the particular manner in which the circuits are arranged, with a view to obtain the following objects: reduction of the length of the two circuits, reduction of the weight of materials employed, ventilation, facility of manufacture and repair, efficiency of insulation, and reduction of cost of manufacture. The author divided modern transformers

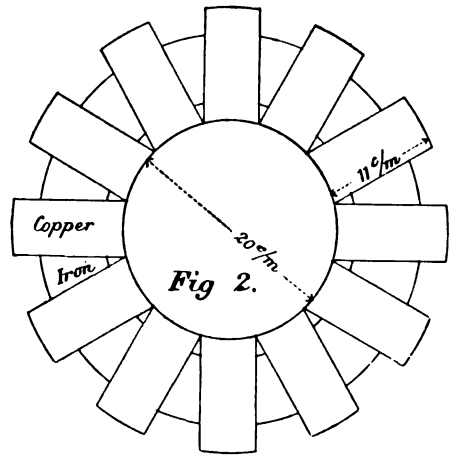

Fig 2.

into two classes—"core transformers," where the iron core is more or less enveloped by the copper coils; and "shell transformers," where the copper coils are more or less enveloped by an iron shell. As familiar examples of these two classes he cited the ordinary Gramme ring and the Zipernowski type of transformer, and part of the paper was devoted to a comparison between the merits of these types. To obtain a basis of comparison he assumed two transformers to be made, of circular ring shape, and of the same over all dimensions (Figs. 2 and 3). The

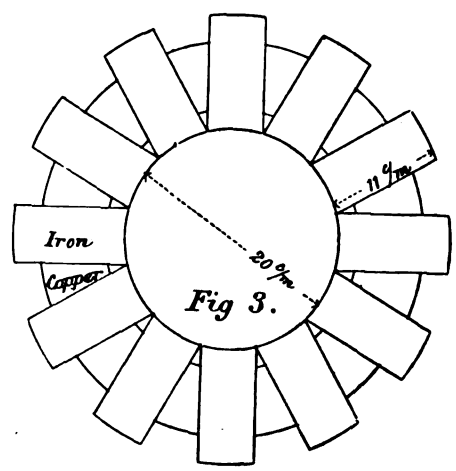

Fig 3.

internal diameter of the ring is 20cm., the cross sectional diameter 11cm., and the external diameter therefore 42cm. The circular cross section is made up by the iron core and the copper coils in the Gramme ring (Fig. 2), and by the copper coils and the iron shell in the Zipernowski ring (Fig. 3). An insulating space of 2½mm. between the core and the primary and between the primary and secondary circuit has been assumed in all cases, so that the available space for copper and iron in each type amounts to 10cm. The author then investigated how much of this space should be filled with iron and how much with copper, in order to obtain a maximum output with a given rate of heating, and maximum output under the condition that the electromotive force between the secondary terminals should not vary by more than 2 per cent. between full load and open circuit, if the e.m.f. on the primary terminals is kept constant. The theoretical part of this investigation was based on his graphic method of dealing with induction coils, which was published in *Industries*, Vol. II., page 360; but he has amplified the method then given by including the phenomenon of hysteresis or molecular friction in iron which causes heat. It is evident that the more heat is developed in the iron core itself, the smaller is the margin left for the heating of the copper coils, so that the output of a transformer becomes reduced as the amount of heat developed in the core increases. In calculating the output for the two types of transformers above described, an induction of 8500 lines per square centimetre and a period of one-eightieth of a second were assumed, under which conditions, according to Professor Ewing, the heat generated by viscous hysteresis amounts to 5000 ergs per cycle, or about 30 per cent. more than would be the case if the iron were carried slowly through a complete cycle of magnetisation (static hysteresis). The effect of hysteresis will be clear on a comparison of the two diagrams (Figs. 4 and 5), the former showing the original method, where hysteresis was neglected, and the latter the method under which it is taken into account. The circle represents the effective exciting power, which is assumed to coincide with the magnetisation, so that the projection on the vertical of the radius O P as it revolves clockwise round O represents the effective exciting power in ampère turns, and to a different scale; also the flow of force at any instant. The line representing the current in the secondary lags behind O P by a quarter cycle, and can be calculated according to a well known formula, from the maximum induction, number of turns, and resistancy of this circuit. This gives also the exciting power of the secondary circuit. Let O J_2 in Fig. 4 represent its maximum; then by erecting a vertical

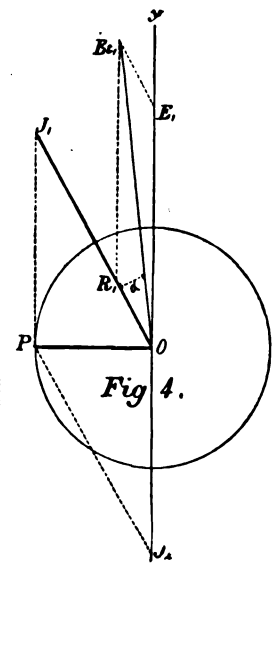

Fig 4.

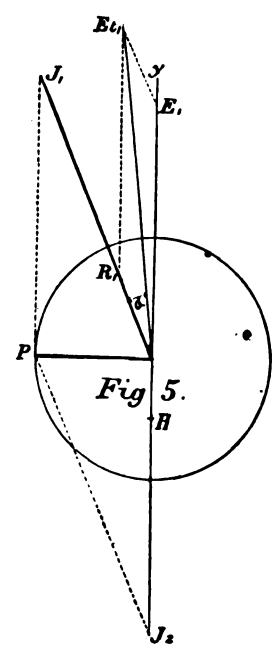

Fig 5.

on O P in P, and making P J_1 equal to O J_2, we find the line O J_1, which represents in position and magnitude the maximum exciting power due to the primary coil alone. This gives also the primary current, and the loss of e.m.f. due to the resistance of the primary coil can now be calculated. Let O R_1 represent this, and O E_1 on the vertical the counter e.m.f. of the primary, which is calculated from the total induction and number of turns. Then the parallelogram O R_1 E_{t1} E_1 gives the point E_{t1} and the line O E_{t1}, which represents in position and magnitude the maximum e.m.f. impressed on the terminals of the primary coil; whilst α is the angle of lag of current behind impressed e.m.f. The work absorbed in the primary coil is represented by the product of mean primary current, mean primary potential, and the cosine of the angle of lag; but in modern transformers the lag for full load is so small that the work absorbed is very nearly represented by the product of current and potential. In order to include the phenomenon of hysteresis, the author assumes that the rate of dissipation of energy by hysteresis follows the same law as the rate of dissipation of energy by eddy currents. When the induction passes through zero, the rate at which heat is generated would then be a maximum, which would gradually diminish to zero as the induction approaches its positive or negative limit.

Digitized by Google

On this assumption he imagines an iron core, perfectly devoid of hysteresis and eddy currents, substituted either by imperfectly sub-dividing the iron core, or by wrapping round it a closed conductor of such resistance as to generate the same heat which in ordinary iron would be generated by hysteresis. The current in the third coil

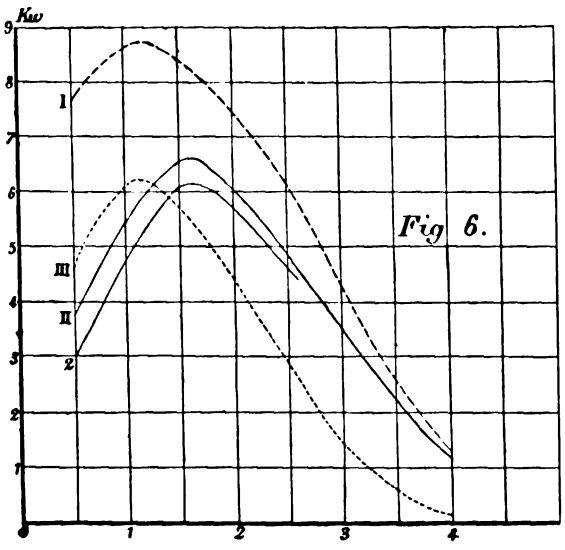

Fig 6.

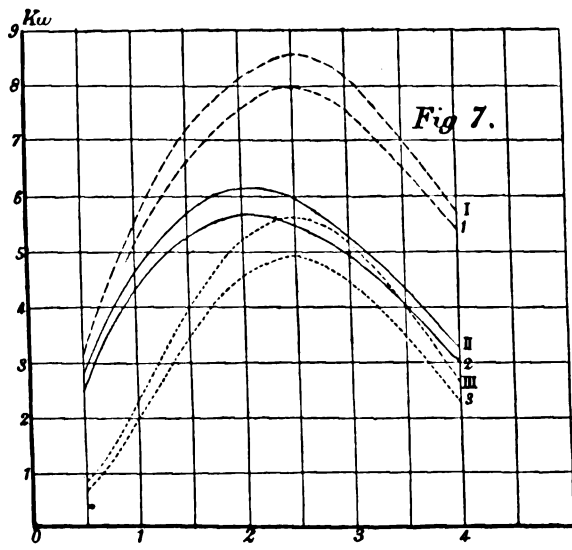

Fig 7.

would coincide with that in the secondary coil, and its exciting power would be added to it. This exciting power can now be represented by a length on the vertical in Fig. 5. Let O H represent the maximum value of this fictitious exciting power, and H J_2 the real exciting power due to the secondary coil, then O J_2 is the exciting power which must be overbalanced by the primary circuit, and the point J_1 in Fig. 5 will consequently be pushed higher up than it was in Fig. 4, the net result of the alteration being an

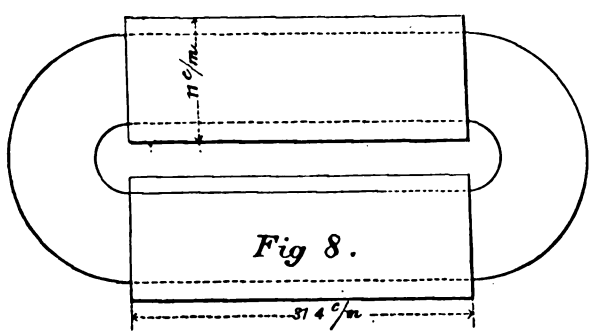

Fig 8.

increase in the amount of energy which must be supplied to the primary coil. By using this method for determining the output of the Gramme and Zipernowski rings, the author finds a series of results which are represented in the curves Figs. 6 and 7 respectively. The primary potential was assumed at 2000 volts, and the secondary at 100 volts. The total amount of heat which may safely be generated in each transformer was assumed to be 260 watts. In Fig. 6 the thickness of copper winding in centimetres is plotted on the horizontal, and the output in kilo.-watts on the vertical; whilst in Fig. 7 the thickness of the iron shell is plotted on the horizontal, and the output on the vertical. The curves I show the output which could be obtained if hysteresis did not exist, the curves II give the output allowing for hysteresis, and the curves III show the output as regulated by the condition that the pressure should not vary more than 2 per cent. The curves marked 1 2 3 give the output under similar conditions for a transformer made as indicated in Fig. 8. A glance at the curves shows that, both as limited by heat and as limited by self regulation, the ordinary Gramme ring is better than the Zipernowski ring. This result, however, refers only to the circular ring type, and if we so alter the shape as to reduce the length of the electric circuit, even if that of the magnetic circuit is thereby slightly increased, the shell transformer becomes actually the better type. The characteristics of the two types are given as follow: Core transformers consisting of one iron core and two sets of coils, and shell transformers consisting of two cores and one set of coils. Various transformers were exhibited on the table and described. The author also described two safety appliances by which the danger of leakage from the high tension to the low tension circuit is avoided. One of these is Mr. Kent's dividing sheet, consisting of a thin metal plate placed between the primary and secondary coil and connected to earth. Upon the insulation of the primary failing the leak is thus carried to earth before it can reach the secondary. The other appliance is the invention of Captain Cardew, and is based upon the electrostatic attraction between a platinum foil and a disc placed above it, which are respectively connected to earth and to a point on the secondary circuit. Upon the potential of the secondary circuit attaining any dangerous amount, the foil is attracted, and the contact causes a fuse wire to melt, which releases a short circuiting contact on the primary, thus causing the fuse of the latter to melt. Referring to the application of transformers, the author distinguished between the English, American, and Continental practice. In all countries the transformers are worked in parallel; but whereas here each subscriber has a separate small transformer on his premises, in America the transformers are fixed out of doors on the same poles which carry the primary and secondary mains, and in some continental installations there is a complete network of secondary mains laid underground in the same manner as if the supply were on the direct system, and this network is fed at certain points by large transformers which are not within the reach of the subscribers.

Mr. Kapp's paper was followed by one by Mr. J. Kenneth D. Mackenzie, dealing with the general subject of the distribution of electricity by transformers. We shall give an abstract of this paper in our next issue.

THE SEEL GLOW LAMP.

A new glow lamp, which has been invented by Herr Seel, is now being largely introduced in Berlin electric light installations and elsewhere in Germany, under the name of the "Berlin Glow Lamp." It is made either with a single or double filament, and of a power of 8, 10, 15, 20, and 30 standard candles, but recently larger lamps, giving a light of from 200 to 300 standard candles, have also been manufactured. The voltage varies from 35 for the two smallest lamps to 50, 65, 90, and 100 volts for the larger sizes. The inventor claims that in small lamps the energy required per candle is about 3 watts, but in the 200-candle size only 2 watts. The pear-shaped globe, as usual in several modern lamps, has no point in the centre, so that the light is freely emitted in all directions. The lamp is provided with a metal socket, into which it is cemented by plaster of Paris, but the end face of the socket is protected by a disc of serpentine, through which the lamp wires pass. In this way the plaster of Paris is prevented from absorbing moisture. A special fitting is used in connection with this lamp. The socket is fastened by a bayonet joint into a somewhat larger socket which is free to revolve on a plate, on the face of which are spring terminals of the branch wires, which are brought through the tube of the bracket. Two little studs, which are screwed into the serpentine plate, and are connected with the lamp terminals, form the contact with these springs when the holder is turned into a certain position. When the holder is turned 90° on its vertical axis this contact is interrupted, so that the light is switched on and off by turning the whole lamp with its holder on its axis. In order to avoid touching the lamp itself when switching on or off, the outer socket is provided with a slot, into which engages a pin on an arm, the prolongation of which is shaped into a handle of about the size used with an ordinary gas tap. By turning this handle the rotary movement in one or the other direction is imparted to the outer socket, and to make sure that even in careless hands the quarter turn should be fully completed, so that the contacts shall be either completely made or completely broken, the spindle of the tap is provided with a disc having flats, against which presses a spring.

The filament is prepared from a vegetable or animal fibre, the exact nature of which the inventor keeps secret. In cross section the filament is triangular, and consists of three layers, which are prepared in the following way: After the raw material is cut up into strips of suitable length, it is saturated with a solution of Senegal gum, a silicate, and caustic soda. Under this treatment it becomes plastic, and is pressed through hot rollers having triangular grooves, the object of the process being to completely fill the pores with the deposits from the solution, and to make the whole filament of equal homogeneity. After carbonising the centre of the filament consists of carbon, upon which is deposited a layer of silicate, protecting the carbon from contact with the air, and at the same time insuring great toughness. The third layer consists of carbon, which is deposited after baking, and by means of which the resistance of the filament is adjusted. In other glow lamps, as usually manufactured, this deposit is provided in what is technically termed the flashing pan, that is to say, the filament is put into the glass globe, the latter is filled with some hydrocarbon gas, and a current is passed through the lamp, heating the carbon filament unequally. In those places where the resistance is highest the filament becomes hottest, and there the carbon is most readily deposited. In this way uniformity of resistance throughout the length of the filament is obtained, and the total resistance of the lamp adjusted. Herr Seel, however, proceeds in a totally different way. He flashes his carbons, if such a term may be applied to the new process, before they are put into the glass globes, and instead of using hydrocarbon gas, he uses solid paraffin for the purpose. A number of baked filaments are attached by small clamps to the under side of a disc forming the cover of a vessel, which is filled to the top with molten paraffin. The vessel is left to cool until the paraffin solidifies, and then a current is sent through the filaments embedded in solid paraffin. Under the heat of the current the paraffin immediately surrounding each filament becomes first liquefied, and ultimately transformed into paraffin vapour, from which the carbon is thrown down on to the filament in those places where the temperature is highest. By this method of flashing air is excluded from contact with the carbon without having to previously seal up the filaments in the glass bulb of the lamps themselves. After the desired resistance has been reached the current is interrupted, and the rest of the paraffin is melted again by the application of external heat. The cover with the filament attached can then be taken up, and the filaments are ready for mounting. The lamp terminals consist as usual of two platinum wires, which are fused into the bottom of the glass globe. The connection between these wires and the filament is made in the following way: The ends of the wires are shaped into small cups, into which fit the ends of the filament, and the whole is then laid into a mould from which the air can be exhausted. When that is done a viscous paste of graphite and albumen is allowed to enter at the two junctions, filling up all the interstices and forming a kind of cement. After a further application of heat this cement sets hard, and the filament with its terminal wires is ready to be placed in the glass globe, when the manufacture proceeds in the same way as with other glow lamps.

PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING.*

In the present paper the author purposes confining his remarks to those branches of electric engineering which involve the employment of considerable power, and are in some way connected with the use of dynamo machines. The principal of these may be treated under the four following heads: (I.) Electric Transmission and Distribution of Power; (II.) Electric Locomotion; (III.) Electric Lighting; (IV.) Electric Metallurgy.

I. Electric Transmission and Distribution of Power.

In the near future this branch of electric engineering will probably occupy more attention and call forth more outlay of capital than either of the three others mentioned above; already, indeed, it is commanding a great deal of attention. Owing to its simplicity, the ease with which an electric motor can be applied to any purpose requiring power, and its high efficiency, it is certainly an approach to an ideally perfect system of transmission. No greater contrast can be imagined than the difference between the position of electricity in this country and in America. On the other side of the Atlantic, although the science of electricity is much behind, the practice is far ahead of our own. European science has supplied an agent, the value of which has been recognised by American engineers; and now in the United States the applications of electric motors are already rivalling, and will soon excel in importance, the application of electricity for lighting purposes. It is to be remembered, however, that there, owing to the high price of coal, the use of steam power is a more serious consideration than here; they have also in many places abundance of water power, which can be utilised by electric transmission. Notwithstanding these differences, there is in our own country an almost unlimited field for the employment of this mode of transmitting power cheaply to a distance, and of distributing power generated at a central station to a number of users in the neighbourhood. Were it not for the cost of the dynamos and motors, electricity

* Paper read before the Institution of Mechanical Engineers, on the 3rd inst., by Mr. Wm. Geipel, of Edinburgh.

Digitized by Google

would supersede to a great extent the use of belts and shafting. In large works, where high speeds are required and the demand for power is variable, the efficiency of belts and shafting is very low indeed. As much as 25 per cent. of the power may be absorbed by the shafting when the full number of machines are in use; and in such a case, with half the machines in use, the loss of power rises to nearly 50 per cent., while in the extreme case of driving a single machine even 99 per cent. may be lost. With electricity, on the other hand, no power is being used in keeping the transmitting medium in motion, the conductor being stationary; the loss takes place only whilst power is actually being used by the motors, each of which drives its own machine. In fact, the percentage of power lost in the transmitting medium becomes smaller as the amount of power transmitted is reduced, which is exactly the converse of what happens with belting and shafting. For the sake of illustration and comparison, let it be assumed that a loss of 25 per cent. of power would take place in the electric conductor when the full load is on, although in reality the loss would never be above 10 per cent., and need not be more than 5 per cent. Then with half load the loss would be 12½ per cent., and so on; and with one machine possibly one-tenth of 1 per cent. might represent the loss in the conductor. When it is remembered in how many cases the average load in a factory is less than half the maximum, it is evident that this point is one demanding the greatest consideration. In New York, where a large number of motors are supplied with current from the electric light mains, it has been found by experience that on an average less than one-third of the whole number of motors are in use at any one time. The depreciation of the electric conductors is comparatively small; but whether the saving of renewing belts and of lubricating shafting would not be counterbalanced by the wear and tear of motors, is a question to be settled by individual experience. The advantage, however, of getting rid of shafting, thereby obviating the necessity for additional stability in the building, and doing away with constant lubrication, and the further advantages of saving the space and light absorbed by belts, and of the ease with which the conductor can be shifted to suit any desired alterations in position of machines, are also very important matters. The distribution of power by electricity from a central station to small users will, in the author's opinion, form in many towns a larger business than the lighting. Both can be done from the same mains and generators, just as is the case with gas; it is merely a question of economy and convenience as to whether gas or electricity should be used. The encouragement of small industries has long demanded some cheap means of obtaining power in small quantities, say from ½ h.p. to 25 h.p. The gas engine has not altogether met the requirements of small establishments, although needing but little attendance; for the first cost of even a small engine is high, and the amount of gas consumed is large. Moreover, the speed is generally irregular, owing to the intermittent impulse, which is more especially noticeable with light loads; and a considerable amount of wear and tear takes place in the valves and working parts. An electric motor can be started and stopped at will with the greatest ease; it requires the smallest amount of attention, occupies the minimum of space, and can be placed in almost any position. An ordinary shunt wound motor will run at an almost constant speed, with a maximum variation of only 5 per cent. from running light to fully loaded; this fact was first pointed out in an interesting paper in the *Philosophical Magazine* for January, 1886, by Mr. Mordey, who has done much valuable work in the perfecting of the modern dynamo machine. This exceedingly close regulation was obtained by using a simple shunt motor of suitable construction, and without any accessories such as the many forms of governing devices to which so much attention had previously been devoted. The result shows that such a motor possesses a practically perfect power of self control, not only over its rate of speed with varying load, but, what is of equal importance, over the energy absorbed by it; for it helps itself, as it were, to only such an amount of energy as will enable it to deal with the work imposed on it. Another advantage in the use of shunt motors is that they act as generators when themselves driven by any extraneous power, without any complication of switch gear, such as is required with a series motor. This fact was first pointed out by Sir William Siemens in a paper read before the Society of Telegraph Engineers, 3rd June, 1880. In such a system, where railways, lifts, &c., are being worked by motors, the current generated by descending trains or loads might suffice at times to supply the rest of the motors with sufficient current for their work, without absorbing any current from the dynamo; at any rate it would reduce the amount of current required to be supplied by the dynamo. The first cost is also small compared with that of a gas engine. A one h.p. motor will cost £20, against £100 for a gas engine. The cost of running a gas engine is about one penny per horse power per hour for gas alone; the same power generated by a dynamo driven by an efficient steam engine costs only about one farthing, current being supplied from street mains just as gas is. As small steam engines are being superseded by gas engines wherever the outlay for the latter can be afforded, the competition in regard to small power lies between gas and electricity, and steam may be left out of the question. There is of course a limit above which steam becomes the cheapest; and probably 10 h.p. may be taken as about that limit in this country. In Boston, in the United States, where some hundreds of motors are supplied with electricity from central stations, they range from ½ h.p. to 15 h.p., and are working lifts, printing establishments, small machine shops, and watch making, tailoring, boot making, and similar industries. Their working seems to be highly appreciated; and the author understands the users would be willing to pay even 25 per cent. more for them, in consequence of their convenience and regularity in working. In Geneva, within a radius of a mile and a quarter there are no fewer than 175 motors at work, varying from ½ h.p. to 70 h.p., supplying power to small workshops and for other purposes, the electric power being obtained from dynamos and turbines which are driven by water power derived from the Rhone. The installation is paying its way, and is about to be largely increased. At the Falls of Niagara plant is being put down to distribute power obtained from the falls to neighbouring towns, including Buffalo, which is twenty miles distant; the amount of power is stated at 15,000 h.p., of which 10,000 h.p. is contracted for at £3 per h.p. per annum for power and lighting purposes in Buffalo.

As an interesting example may be mentioned a 6 h.p. motor recently erected by the Brush Company of Cleveland, Ohio, in a printing establishment, where it was connected with the regular arc light circuit. It takes the place of a 10 h.p. steam engine, which had sometimes come to a standstill under its load. It drives about 70ft. to 80ft. of shafting, three cylinder presses, four platen presses, one large paper cutter, and one heavy lift; and by a 4in. belt carried up through three floors it also drives three ruling machines and four paper cutters. It does its work splendidly, and its motion is steady and regular. It has proved to the proprietor's satisfaction that printing offices could well afford to employ electricity instead of steam, even in cases where the first cost might be more. In many other towns in America, where the electric light mains are within reach, the number of motors already in use is very great; within two years 5000 motors have been supplied by one firm alone, and the author understands that the Brush Company are turning out as many motors as dynamos. In some places in this country, and more especially in Lancashire, it is customary for power to be supplied from a large steam engine to neighbouring buildings, which are let out as separate workshops. In such instances, however, the power supplied is more frequently above than below 10 h.p., and probably it would not pay to introduce an electric motor. Still it should not be forgotten that in renting these workshops considerable inconvenience may be incurred as regards the locality of the premises for the manufacture; moreover, the rent is often disproportionately high. Many schemes have been propounded for distributing power in manufacturing districts by means of steam, compressed air, and water pressure, each of which is in use to a somewhat limited extent; and as all of them have been known long enough, it may seemingly be inferred from their limited employment that there is not much to recommend their extended use commercially. With steam, the condensation in the pipes causes loss of pressure, and results in wet steam being supplied to the engines. Compressed air cannot efficiently be worked expansively, and is attended with loss of heat in the compressor. Water pressure commonly involves using the maximum power, whatever the work required. Besides these prominent faults of the three several methods, what is of the greatest importance and common to all three is that the generating plant has to be used almost exclusively for supplying the power, and cannot be utilised for other purposes in addition; whereas with a central electric station the engines and dynamos serve to generate current for lighting purposes also at night.

Collieries.—In collieries electricity will be largely adopted in the near future. For underground hauling, pumping, ventilating, and drilling, it can readily be applied with an efficiency double that of the compressed air. With a well arranged installation 75 per cent. of the brake power of the engine will be utilised on the shaft of the motor. For hauling and pumping, wire ropes or rods are the greatest competitors of electricity, which obviates the following disadvantages in connection with them: Chance of breakdown through strain; wear and tear; mishap to guides through falls of roof or dirt; trouble and expense of oiling the guides; and room required at pit mouth or at bottom for engine, pulleys or levers, or other gear. As the tendency in mines in this country is towards a reduction of working hours, the question of mechanical haulage becomes most important, because horses must be fed whether at work or idle, and the cost of haulage by horses therefore increases as the working hours become reduced. For ventilating and drilling, compressed air is perhaps most largely used; and one of the great points in its favour is that the exhaust is available for supplying fresh air to the miners, and for driving out the foul gas after the firing of shots. But the cost of the compressed air machinery is heavy, as is also that of the pipes for conducting the compressed air from the compressor to the place where it is used. The cost of electric plant is somewhat less, and the efficiency is very much greater; while by using old haulage ropes as conductors the cost of this item is rendered very small. At Trafalgar Collieries, in the Forest of Dean, there is an interesting instance of pumping on a small scale. A Gramme machine driven at bank supplies current to a motor in the mine 800 yards distant from it. A current of 15 ampères at 100 volts, equal to 1500 watts or 2 h.p., is found sufficient to work the pump, which is double acting, 5in. diam. and 8in. stroke, and runs up to 70 revolutions or 35 gallons per minute, lifting about 90ft. The entire installation cost £250; it has been working about four years, and has given so much satisfaction that additional plant has lately been put in at a distance of 1650 yards from the pit shaft for lifting 120 gallons per minute 300ft. high, the distance between the pump and generator being 2200 yards. A double throw pump with 9in. plunger and 10in. stroke is driven at 25 revolutions per minute by spur gearing reducing 6 to 1, the small pinion being driven by a belt from the motor. Current is conveyed to the motor by a conductor composed of nineteen wires No. 16 S.W.G. (0·065in.) thick, giving 0·065 sq. in. total sectional area, insulated and carried on earthenware insulators; an old 4in. wire rope serves for the return circuit. The efficiency obtained throughout is only 35 per cent.; but as much as 6·49 h.p. or 22 per cent. is lost in the engine alone, which is an old one. The cost of engine and electric plant and pump complete was £774, without pipes. The weekly cost of maintenance is given as follows by Mr. Brain, the colliery manager:—

	£	s.	d.
Engineers, half time	1	8	0
Men underground, full time	2	9	0
Small coal consumed, say 36 tons at 1s.	1	16	0
Oil, waste, and sundries	0	7	0
Interest and depreciation, say 15 per cent.	1	17	0
Total per week	£7	17	0

Total per annum, £408, showing a yearly saving of £470 on the water power that was superseded. The cost of the water raised is 0·02 penny per h.p. per hour, and 1·8 pence per 1000 gallons. At the same collieries a 6ft. fan is also being worked by an electromotor at 1800 yards distance from the generator. Another interesting example of pumping is afforded by the recent introduction of electricity for this purpose into St. John's Colliery, Normanton, where 39 gallons per minute are raised 530ft., equivalent to 6·3 h.p. of work done. An old girder beam engine is utilised to drive the dynamo, and indicates 14·2 h.p. with full load. The efficiency throughout is therefore 44·4 per cent. The power lost in the different stages is as follows:—

	h.p.		per cent.
Engine and dynamo running light	1·7	=	12·0
Conductors	0·88	=	6·2
Motor and first shaft	2·8	=	19·7
Driving pump empty	2·0	=	14·1
Other losses	0·52	=	3·6
Total loss	7·9	=	55·6
Useful work	6·3	=	44·4
	14·2	=	100·0

It will be seen that only a small part of the loss takes place in the electrical plant, the greater part occurring in the pump, engine, and gear. The pump is driven by toothed wheels, which are worked from the motor by a cotton belt, in order to obviate transmitting the vibrations of the pump back to the motor. This plant is being extended to pump in addition 120 gallons per minute against a head of 900ft. At Thallern Colliery, on the Danube, where electricity has replaced steam for pumping, it has been found after several months' work that a considerable saving in coal is effected; also that the temperature of the pit is reduced some 14°F., steam having previously rendered the atmosphere of the mine unbearable. In the mines of Blanzy, in France, a ventilating fan is driven from a generator at bank. The fan is 150 yards in, 2½ft. diam. by 11¾in. broad, and runs at 730 revolutions per minute. The temperature at the face has been reduced 15 degrees, from 95°F. to 80°F., since its introduction.

Shipyards.—In shipyards and similar works electricity has already proved itself a suitable and economical means of transmitting power for riveting, drilling, &c. The electromagnetic tools described in Mr. Rowan's paper at last year's summer meeting* are being successfully employed in yards at Dumbarton. This system possesses the additional advantage that the tool can be firmly held to its work by magnetic attraction alone, without the use of bolts, so that no holes need be left for hand riveting, as is required with other machine riveters.

PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING.

FIG. 1.

Colonies, although even in the small sluggish rivers of this country there are large amounts of power running to waste. In many places where works have been erected for utilising water power, it has been at the sacrifice of convenience of situation, or of a ready and cheap means of receiving and dispatching goods; whereas by means of electricity the same water power might have been transmitted to a locality more suitable for the works. For short distances it does not pay to transmit water power by electricity, owing, as previously mentioned, to the cost of dynamos; in such cases transmission by shafting or wire ropes is cheaper. But for long distances shafting is out of the question, wire ropes become more expensive, and electricity is cheapest. In Table I. is shown the first cost of plant per horse power transmitted through different distances by electricity, water, air, and wire rope. There is, of course, a limit beyond which it would not pay to transmit power, because with the distance the capital outlay increases, until the interest thereon outweighs the cost of the coal which would be consumed by a steam engine on the spot. Wire rope is perhaps cheaper for distances of less than one mile, although the disadvantages of having to lubricate pulleys and to provide substantial supports would in many cases compensate for the higher cost of electricity. The limit of distance to which it is economical to transmit water power increases with the amount of power transmitted. From Table II., showing the cost of one horse power per hour,* it appears that, when the power is generated by a fall of water, 5 h.p. can be transmitted 11,000 yards at the rate of 0·52 penny per horse power per hour by electricity, while at the same rate also 100 h.p. can be transmitted 22,000 yards, that is, double the distance. The transmission of steam power over long distances is seen from the same table to be not economical; small powers, say up to 10 h.p., may be transmitted as far as three miles; but larger powers not so far, because for larger power a local engine becomes more economical. As an interesting instance of the transmission of power by electricity over long distances, that at the Phœnix Gold Mines in New Zealand† may be referred to. The current is generated by two No. 8 Brush machines, each capable of giving 20,000 watts or 26 h.p.; they are driven by Pelton water wheels, with a head of 180ft. The current is conveyed to the motor about three miles distant, and back again, by a No. 8 B.W.G. copper wire (0·165in. thick) nearly six miles long, supported on telegraph poles. The power lost in the line is only 3 h.p. A Victoria motor is used, running at about 350 revolutions per minute; and the power is transmitted to the machinery by a belt. Deprez succeeded in demonstrating practically that 52 h.p. could be transmitted over a distance of 35 miles, viz., from Creil to Paris, through a copper cable equal in section to a wire of less than 0·2in. diam. But his machines were not efficient, the power required to drive the dynamo being 116 h.p., of which 44 per cent. was lost in the dynamo and motor, and 11 per cent. in the 70 miles of the outward and return wire. There is no reason, however, why much more efficient results should not have been obtained; as much as 18 per cent. of the total power was absorbed for maintaining the magnetism of the field of the dynamo, whereas in a well designed machine less than 5 per cent. should suffice. Mr. C. E. H. Brown, of Oerlikon, has succeeded in transmitting by electricity 50 h.p. from water power at Kriegstetten over a distance of 5 miles to Solothurn in Switzerland, with a commercial return of over 70 per cent.‡ Two series dynamos and two series motors are arranged on the three-wire system. Each of the three wires is ¼in. diam., consisting of bare copper suspended on poles about 40 yards apart, with fluid insulators for insuring good insulation. For a span of 130 yards across the river Aare, silicium bronze wire is used, which has the same conductivity as copper, and a tensile strength of 30 tons per square inch. The current used is 15 ampères, and the potential difference at the terminals of each dynamo is 1250 volts. The resistance of the line is 10 ohms, and the loss in it is a little over 3 h.p., or 6 per cent. of the total power. The loss in dynamos and motors is 24 per cent., being much less than in Deprez' machines, where it was 44 per cent. At Hatfield, on the Marquis of Salisbury's estate, the river Lea is utilised to generate electricity, which is transmitted to the house and over the estate for a variety of purposes. Two turbines are used, one to drive a 40 h.p. Siemens alternating current dynamo for lighting the house, and the other to drive a 16 h.p. Brush machine for arc lighting at night, and in the day for working the motors at the house and on the farm. Those at the house drive pumping and ice making machinery, and a 24in. Blackman air propeller fixed in the roof for ventilating; on the farm the motors are used for elevating hay and corn sheaves to the tops of the stacks, for threshing, for cutting rough grass with a chaff cutting machine for ensilage, in fields extending to a distance of two miles, for grinding corn, &c., to make fodder, and for other purposes. The motors have also been used for pile driving, for making coffer dams where necessary in the river, and also for dredging the river and clearing it of weeds. A Gramme motor capable of raising 2500 to 3000 gallons per hour, pumps the town sewage into a tank at a height of 30ft. for irrigation. The conductors are carried overhead on poles about the farm, and underground in wooden troughs to the house. In favourable districts the supply of power to farmers by means of electricity is a subject well worthy the consideration of capitalists. If water power is not to be obtained as the prime mover, then steam power must be used as is now the custom, but in a more economical form than in a portable or traction engine. The expense of taking these engines about the farm, both in coal and wages, must render them costly to the farmer in respect of the power actually used. An economical engine could be fixed for generating an electric current to be transmitted through overhead conductors carried on poles along the roadside.

* This is a modification of a table given in Mr. Kapp's work on "Electric Transmission of Energy." The original table is based on the investigations of Herr Beringer and on the cost of power as determined by Professor Grove.

† *Industries*, Vol. I., page 594. ‡ *Industries*, Vol. IV., page 18.

II. Electric Locomotion.

The practical methods of accomplishing electric locomotion seem to the author to be the four following: Firstly, the use of a third insulated rail or conductor to convey the current from the generator to the motor carried on the locomotive, contact being made by a wheel or a sliding spring or brush; while the two ordinary rails serve as a return circuit, the current being conducted from the motor to the rails through the frame, axle, and wheels of the locomotive. Secondly, the employment of an overhead conductor supported on poles or from the roof of an arch or tunnel, contact being made either by a carrier on wheels running along the conductor, or by rubbing. The return circuit may be either through a second overhead conductor, or through the ordinary rails as in the third-rail plan. Thirdly, the use of an underground insulated conductor, placed in a conduit between the rails, and conducting the current from the generator through a contact carriage to the motor, whence it is conveyed back through the frame, axles, wheels, and rails. Fourthly, the employment of storage batteries, placed preferably under the seats of the car, with the motor and gear underneath, or the whole placed on a separate locomotive. The plan of using the ordinary rails as positive and negative conductors, and insulating the wheels or axles of the cars, is attended with the objection that, owing to the rail supports having to carry heavy loads, there is difficulty in insulating the rails sufficiently to prevent excessive leakage to earth. Of these four methods the first two are the cheapest and most efficient, but are applicable only to railroads; while the two other plans, of an underground insulated conductor, and of storage cells on the car, are both applicable to street tramways.

Gearing.—Owing to the high speed at which electric motors require to run, and the limited space available for them to occupy, the mode of gearing the motor to the axle of the locomotive or car forms an important consideration, more especially in places where the motor is placed upon the car which carries passengers, when noise and vibration would be most objectionable. The following five methods of gearing are those more generally employed: (1) Worm wheel gearing; (2) pitch chain gearing; (3) leather belting; (4) rope, either endless or not; (5) toothed wheels. Worm gearing appears from Mr. Holroyd Smith's experience at Blackpool, where his electric tramway is worked with an underground conductor, to be the best for tram cars. Although, as a rule, it is not efficient, yet if well designed and properly lubricated it can be rendered more efficient, and probably is fairly suitable for this purpose. Some tests made by Mr. Reckenzaun show a maximum efficiency of 87 per cent. The author thinks that a combination of toothed wheels and friction gear, such as has been introduced by Mr. Raworth for driving dynamos in electric lighting with excellent results where space is a desideratum, would make a silent working and durable form of gear: the friction gear would serve to reduce the speed from a motor to a counter shaft; and from the latter the driving wheels of the car would be driven by toothed wheels. The form of gear employed of course depends greatly upon the nature of the traffic and of the rolling stock.

Third Insulated Rail.—As an example of an electric railway with a third insulated rail, that at Portrush, Ireland, is probably the most interesting, as being one of the first started in the world and also the longest; its total length is six miles. The accompanying diagram (Fig. 1) has been kindly lent by Messrs. Siemens, by whom the railway was planned. Power is generated by two 50 h.p. turbines, driving a dynamo which is capable of generating 100 ampères at 250 volts; the current is transmitted from the river Rush through a distance of 1600 yards to the railway, the resistance of the line being 1·9 ohm. Pitch chain gearing is used, and gives satisfaction. The working expenses amount to less than threepence per car mile.

Another instance, also in Ireland, is the Bessbrook and Newry tramway, which is three miles long and 3ft. gauge, and is actuated by water power. A turbine, which develops 62 h.p., drives two Edison-Hopkinson dynamos, each capable of giving out 25 h.p. at 250 volts. The third rail is of channel section steel, supported in wooden blocks, which apparently act admirably as insulators, the leakage being only ¼ ampère per mile, or 0·3 h.p. in all. A train consists generally of one passenger car constructed to carry thirty-eight persons, and three goods waggons, each carrying 2 tons freight. The maximum speed that can be attained is fifteen miles per hour. Here also chain gearing is employed. The cost per train mile is 3·3d. during the busy months, and 4·2d. in slack months; these figures, however, do not include anything for depreciation on the cost of construction of the railway, which was £2,500, nor for general supervision.

Overhead Conductors.—The electric railway at Moedling, near Vienna, is a good example of the employment of overhead conductors. The number of passengers carried during the year 1886 was 342,257, according to Mr. Reckenzaun, and the average cost 3·42 pence per car mile; the coal consumption per car mile was 13·4lb. of very inferior brown coal. The current is generated by six Siemens dynamos, driven by three portable engines of 12 n.h.p. each; the use of these engines may account for the somewhat high consumption of coal. The overhead conductors, which are carried on posts 18ft. high and 90ft. apart, consist of slotted tubes in lengths of 15ft. each, soldered together; a contact carriage slides within the tube, which is 1in. diam. inside. Spur gearing is used, but apparently is not satisfactory. The objections to it are the rapid wearing out of the high speed pinions, the great weight of the gear, and the noise and vibration caused.

The Frankfort Offenbach electric railway, which was opened for traffic on 10th April, 1884, is similar to that at Moedling, the current being brought to the moving cars by means of slotted iron tube conductors carried overhead. The length of the line is about 4½ miles; the gauge is 1m. (3ft. 3⅜in.). The sharpest curve has a radius of 98½ft.; the steepest incline is 1 in 30, and only 18 per cent. of the line is level. The average speed of the cars is 7½ miles per hour. Two cars coupled together start from each end of the line every twenty minutes. Each car has seats for eighteen passengers and standing room for twelve more, the gross weight being 4 tons. The motor is placed under the floor of the car, and the connection to the wheels is made by toothed gearing. The generating station is at Ober-rad, about the middle of the line, and contains one twin engine of 240 i.h.p. and one spare engine of 80 to 100 i.h.p.; in regular work one cylinder only of the twin engine is used, giving off 120 i.h.p. The current is generated by three Siemens dynamos, called 300-light; a fourth similar dynamo is in reserve. The working electromotive force is 350 volts. The current generated by the three dynamos is sufficient to keep eight cars running simultaneously. This plan has been most largely adopted in America, where there are probably not far short of one hundred electric railways at work and projected. It has certainly the recommendation of cheapness, for a higher voltage is permissible, and consequently a smaller conductor with less loss of power than in the case of the third rail; this is more especially important for long lines. As an instance of what is being done, a railway of eleven miles length is now in course of construction at Richmond, and forty cars are building to be worked upon it on the overhead system. Another instance is the railway at Scranton, Pennsylvania, which has been in successful operation about a year. It is 4½ miles long; five cars carrying motors from 15 to 20 h.p. are in use, and four cars with 25 h.p. motors are being constructed, each of which will be able to draw two others; the cars carry seventy-five passengers each. The current is generated by two 100 h.p. dynamos driven by two 180 h.p. engines, one set being spare; the potential adopted is 600 volts. The overhead conductors are of copper $\frac{1}{16}$in. diam.; the supporting poles are 100ft. apart, about 20ft. high, and about 6in. diam. at the thick end; the return circuit is through the ordinary rails. The plant is also used for lighting the town. The potential generally employed in America for the longer lines is from 500 to 600 volts; the latter is probably the limit to which it is safe to work. With this potential two ⅜in. copper conductors would serve to work twenty-five cars in parallel, the current per car averaging about 10 ampères. With a voltage as high as this the leakage on the third rail system would be excessive.

Underground Conductors.—Perhaps the most important example of this plan is Mr. Holroyd Smith's electric tramway at Blackpool, which has been in successful operation for some two years. The underground conduit is somewhat similar to that of a cable tramway such as is working at the present time in Edinburgh and on Highgate Hill, London; but instead of the carrier being used to grip a running cable, it is made to rub along a stationary conductor. The cost of working is stated to be less than 4d. per car mile; during one week in the season of 1886 there were 44,306 passengers carried at a cost of £45 for wages and fuel, which is less than one farthing per passenger.

Where an underground conductor is employed, the advantages of having no slit communicating with the surface of the street are so obvious, that an ingenious plan has been proposed by Mr. Frank Wynne for placing the conductor in a hermetically sealed conduit under the line. A small carrier, which acts as a contact maker between the conductors and short sections of rails laid in the road, travels along the conduit, being actuated by a tiny electromotor and by part of the same current which works the tram car above it. An absolute synchronism between the tram car and the carrier is obtained by a simple device. The short sections of rails are in circuit only whilst the car is over them.

A plan has been proposed by Messrs. Ayrton and Perry for making contact between the underground conductor and the section of rail underneath the car, by means of the weight of the car, which actuates an arrangement of levers that make the contact so long as the car is on that section. A plan has also been proposed by them for employing the attraction of a

Digitized by Google

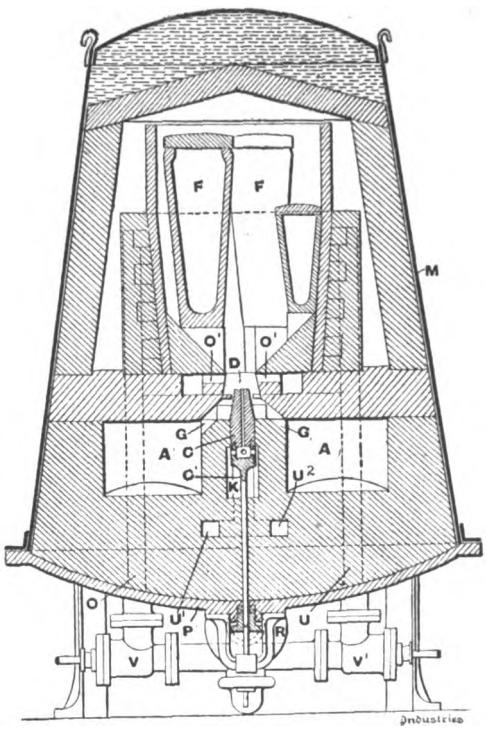
magnet fixed on the car and keepers fixed in boxes underneath the street. The contacts on the keepers are permanently connected with the underground conductor, and when lifted by the attraction of the magnet on the car they make connection with a section of rail, putting the motor in circuit.

Storage Batteries.—Storage batteries on the car have not as yet been much used, though many experiments have been made from time to time. The problem was first attempted by Mr. Reckenzaun, who has done much to perfect the plan. The difficulty is that, if the accumulators are made light, their depreciation is high; while if they are constructed with a thoroughly serviceable make of cell, their weight is very great. The first cost of the cells is also somewhat prohibitive, and their depreciation is high. A trial of this plan on a practical scale is now being made by Mr. Elieson on the North Metropolitan Tramway in London. The storage cells are placed on a separate locomotive car. The motor turns itself round on an upright pivot, by means of a bevel wheel on the armature shaft gearing with a circular rack fixed on the floor of the car; and the revolution of the motor is transmitted to the axle of the car through mitre gear. Trials are also being made in Brussels, in Philadelphia, and in other places; but there appear to be no very reliable data as to the cost of working. The plan has been unsuccessful in the past, owing to the use of inefficient motors and gear, which require of course an increased size of battery in proportion to their inefficiency; the imperfection of the secondary batteries employed, as pointed out, has also prohibited success. With motors, speed reducing gear, and secondary batteries all improved, the experiments now being made bid fair to demonstrate the successful working of tramways by electricity in crowded thoroughfares.

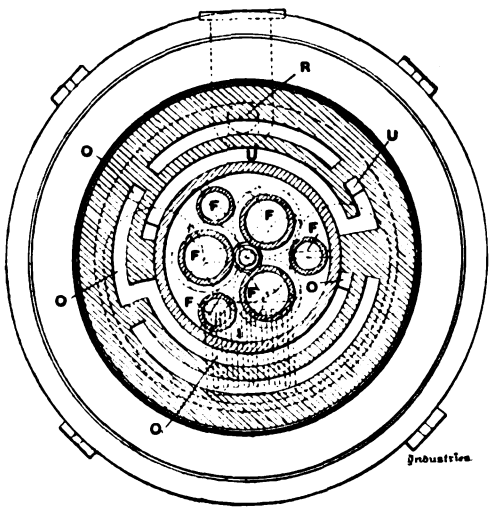
Ordinary Rails as Conductors.—The short electric railway of Mr. Volk, at Brighton, on this system is interesting as being one of the earliest in use in this country. The expenses amount to 2d. per car mile, being made up as follows:—

Gas for engine	1·11	penny.
Wages	0·70	„
Oil and waste	0·07	„
Repair	0·12	„
Total per car mile	2·00	pence.

The total car miles per annum are stated to be 47,000, and the depreciation at 10 per cent. on the £3,000 cost of construction is therefore equal to 1½d. per car mile, thus bringing up the total cost to 3½d. per car mile. Several similar railways are now working or contemplated in seaside towns.



Cost of Working.—From these instances it will be seen that, taking into consideration the fact that the machines here employed are not so efficient as those now being made, an electric tramway may be worked for about 3d. per car mile; and as the cost of horses is from 7d. to 9d. per car mile, the importance of electric propulsion for tram cars and short railways is very evident. At the Antwerp Exhibition, in 1885, when electric locomotion was beginning to receive consideration in its commercial aspect, a series of trials extending over four months on five different kinds of tramway motors resulted in the first place being assigned to the electric car, in competition with the four following plans: The Krauss and the Wilkinson locomotives separated from the car, the Rowan engine and car combined, and the Beaumont compressed air car. The results of these trials are given in Table III.



Notwithstanding that the use of electricity for heavy railway traffic has been predicted, the author thinks that so long as the electricity is generated by dynamos driven by steam engines, steam locomotives will not be discarded in favour of electricity for long distances. But for light railways and suburban lines, underground or overhead, where the use of a steam engine is a nuisance, there can be little doubt that electricity must be largely adopted in the immediate future, as the number of such railways already constructed and in course of planning is now between one and two hundred.

(To be continued.)

OTTO'S CRUCIBLE FURNACE.

We are indebted to our contemporary the *Chemiker Zeitung* for the accompanying illustrations representing a crucible furnace made on the Otto system. The furnace is made of the best fire bricks, and surrounded with an iron shell M bolted to a base plate P. From the generator A the gases are conducted through G into the burner D. The air is supplied to D from four nozzles O_1 connected to the upper air channel O. A perforated cone C is fixed in an air chamber K connected to O, and may be moved up or down, for regulating the draught in D, by means of a rod passing through a stuffing box, and carrying a screw and hand wheel. The gases are ignited at D, and the flame circulates round the crucibles F. A pipe R conducts the compressed gases to the boiler, which supplies the engines driving the air compressors. From the fire box of the boiler the gases are taken to a hot air engine, thereby making extensive use of the energy stored up in the products of combustion. The furnace is started in the following manner: The shell M is removed by means of a crane, and a fire is made in the ordinary way on a temporary grate I. At the same time a fire is made on a temporary grate in the boiler, so as to be able to start the engines. Now the shell M is replaced and bolted down on the base plate P, the engine and air compressor are started, and the valves V and V_1 opened. The pipe connecting the fire box of the boiler with the hot air engine is closed by a valve, until a considerable pressure has been attained. The compressed air enters the air-passages U and O. From U the air passes in semi-circles five times round the shaft of the furnace, and comes considerably heated through the nozzles $U_1 U_2$ into the generator A. The air entering O passes in a similar manner into a circular channel O, as shown in plan. From here it is conducted through the nozzles O_1 and through the perforation in C into D, where it is mixed with the gases passing through G and coming from the generator A, and the mixture is ignited. The flame may be observed through a lens made of mica, and the draught

is easily regulated by means of the cone C. As the parts of the furnace which are exposed to the flame are made of five large fire bricks only, which are able to resist very great heat without softening, the furnace may be taken to pieces and injured parts exchanged in a very short time. The furnace is especially adapted for the cheap production of aluminium bronze and aluminium iron on the system adapted by Cowles for the Electric Smelting Company.

Notes.

CHINESE BRASS AND COPPER WARE.

Large quantities of yellow metal sheathing are now employed by the Chinese in the manufacture of pots, pans, gongs, cymbals, &c., which were formerly cast. The United States Consul at Hong-Kong gives some interesting particulars regarding the native manufacture of hubble-bubble pipes, which is an important industry, some establishments employing over one hundred hands. The workman sits on a low stool in front of a narrow bench about 3ft. long. The metal is cut from the sheets into proper form with shears. The workman then hammers it into shape upon a block of wood with a convex faced hammer. The metal is annealed from time to time by heating in a charcoal furnace and cooling by immersion in water, in order to render it softer and tougher. The different parts are wired together and brazed. After having been filed smooth, the vessel is polished with fine sand and finished with a finely powdered silicious ash, obtained by burning rice husks. Gongs and cymbals are also made from this sheathing by hammering. Pots and pans, after being hammered, have a rounded and thickened edge given them by folding the edge over a wire and then soldering it.

NATURAL GAS AS FUEL.

Experiments for the utilisation of gas in mines are being made at Hebburn-on-Tyne. About six months ago a "blower," which gave forth about 200 cub. ft. of gas per minute, was discovered in one of the mines. A sample was analysed, and found to be suitable for burning purposes, although deficient in illuminating power. The owners of the mine thereupon decided to experimentally use the gas as fuel in the furnaces of the boilers, and are laying down a special set of pipes for transmitting the gas to bank. At the present time the blowers are tapped and diverted into the airways, through which bad air and gas are carried to the surface. The confinement of the gas to pipes will undoubtedly tend to additional safety in the working of the mine, while its consumption in the furnaces of the boilers may promote economy.

ARTIFICIAL SILK.

An artificial textile material resembling silk has recently been described by M. de Chardonnet to the Academy of Sciences in Paris. It is obtained from nitro-cellulose, which is dissolved in a mixture of alcohol and ether, and then treated with a reducing agent, either ferrous or stannous chloride giving the best results. A small quantity of a solution of tannic acid, dissolved in alcohol, is next added to the solution, and the mixture is filtered in a closed vessel to prevent loss by evaporation. This liquid is then placed in a large reservoir, from which a tube with a fine conical nozzle projects. This tube communicates with a vessel filled with dilute nitric acid, and the liquid as it flows into this acid hardens into a fine filament, which is drawn across a space through which a current of dry air is passing, where the thread is finally dried. The filament obtained in this manner is of a grey or black colour; but it can be made in any desired colour by previously dissolving some soluble colouring matter in the ethereal solution. The thread is transparent, cylindrical, pliable, and has a silky appearance. It is not acted upon by dilute acids and alkalies, and is insoluble in alcohol, ether, and hot or cold water. It dissolves, however, in a mixture of alcohol and ether, and in acetic ether. It does not explode when heated, but burns quietly. It bears a considerable weight without breaking (20-30 kilo. per square millimetre). Organzine, and a material resembling weft silk, can easily be manufactured by multiplying the number of nozzles through which the prepared liquid issues. The several filaments consolidate together in the dilute acid, and any desired thickness or strength can thus be readily obtained by altering the number of threads produced. M. de Chardonnet deposited with the French Academy a note describing his invention about four years ago; but it was opened at his demand at their meeting a few weeks ago, in order that he might establish his claim to priority.

BRITISH AND GERMAN BUILT VESSELS IN THE CHINESE NAVY.

A writer in a journal published in China describes four vessels which were recently added to the Chinese Navy, two having been built at Elswick and two at Stettin, and makes a comparison between them. He says the displacement of the German boats is 3100 tons, as against 2300 tons of the English; still they only carry two 21cm. and two 6in. guns, against Armstrong's three 21cm. and two 6in. guns, besides an auxiliary armament of vastly superior importance, while in speed there is also an enormous difference. The German ships only attain a speed of 15 knots, while the English have reached nearly 19 knots. In the matter of protection the latter are also superior. The German armour is laid on in three strakes only 30in. deep, and consequently liable to be easily broken across by a moderately heavy projectile. The upper strake is 8in. thick, the two lower 6in. only. The English armoured deck is 8in. thick, without taking into account the special properties of sloping armour for deflecting shots. The workmanship in general, and particularly the blacksmiths' and shipwrights' work in the German vessels, is very rough indeed. A large number of fittings provided in the Armstrong boats do not exist in the others, and in some instances these omissions constitute extremely grave defects. Among others the writer specifies the means of closing the doors in the water tight compartments in case of accident, the German vessels not being provided with gear above water for opening or closing them; the steering gear where there is an absence of relieving tackle; and the absence of davits for the principal boats, which have to be hoisted out and in by means of large steam derricks. Finally, the decks throughout the crew spaces in the German ships are of ordinary pine, in the Armstrong ships they are of teak.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

10176A. Hahn, E. J. — Carburetters for gas motors. (This application having been originally included in No. 10176, dated 20th July, 1887, takes, under Patents Rule 23, that date.)

27th January, 1888.

1236. Robinson, T. N. — Feed motion for wood planing machines.
1239. Biggin, H. — Chairs for railways.
1240. Holt, T. — Couplings for railway waggons.
1244. Sowden, M. — Looms.
1247. Sewell, S. J. — Type writers.
1250. Immisch, M. — Water wheel for driving electric generators.
1256. Jackson, J. P. — Soda water machinery.
1260. Halliday, T. — Propelling boats.
1262. Cutlan, J. E. — Machines for lasting boots.
1266. Monteith, J. — Starting tramway cars.
1279. Silverman, L. — Ordnance.
1282. Lyle, J. — Automatic retort grate.

28th January, 1888.

1293. Rowe, J. A. — Hydrostatic motors.
1296. Thomson & Biles — Rolling chambers for ships.
1299. Crabtree & Crabtree. — Looms.
1300. Holroyd, J., & others — Yarn machinery.
1306. Tennant & Sharpe — Appliances for getting coal.
1312. Holt & Carter — Mules.
1317. Pearson & Bennion — Self feeding eyeletting machines.
1324. Donkin, B. — Fluid pressure engines.
1329. Gentry, O. H. — Steam boilers.
1331. Thompson, H. — Vertical boilers.
1332. Donkin, G. M. — Excavators.
1333. Gauhe, O. W. — Chain elevators.
1335. Royce, W. — Pumps.
1336. Imray, O. — Starting tramway cars (*Weilbach*).
1340. Willcox, B. — Joining the ends of bands (*Uhlenhuth*).
1341. Evans, J. B. — Wire fencing standards.
1343. Skerrett, H. — Semaphore signals for railways (*Spicer & Schrender*).
1347. Lake, H. H. — Manufacture of screw nuts (*Ibbotson*).

30th January, 1888.

1351. Baraclough, W. H. — Shaping sheet steel.
1355. Howarth, R. — Heating of feed water.
1362. Spencer, J. — Manufacture of gloves.
1375. Archer & Faulder — Hoists or lifts.
1377. Britten, W. E. — Manufacture of boots.
1379. Thompson, W. P. — Braking the motion of machines (*Deimel*).
1381. Blessing, O. — Gas engines.
1382. Peach, C. — Grinding cutlery (*Johnston*).
1385. Chance, G. F. — Kilns for annealing sheets of glass.
1390. Imray, O. — Distribution of oil over rough water (*Stebbins*).
1391. Wyke, W. H. — Rotary engines.
1392. Newlands & Alliott — Apparatus for filtering saccharine liquids.
1397. Immisch, M. — Propellers.

31st January, 1888.

1400. Kitson & Holmes — Pulverising salt.
1402. Paterson, J. — Testing the fairness of crank shafts.
1403. Mansfield, J. W. — Manufacture of boots.
1407. Peltzer-Teacher and Rilke — Stop motion on doubling frames.
1408. Brown & Burnley — Shuttles.
1411. Cunningham, W. — Winding yarn.
1415. Richards, G. — Double acting steam engines.
1419. Thompson, W. P. — Refrigerating apparatus (*Craft*).
1420. Thompson, W. P. — Sewing machines (*Ehrlich and Bendix*).
1421. Boult, A. J. — Magazines for fire arms (*Hindley*).
1426. Madan, C. S. — Steam jet pumps.
1430. Gellert, K. L. — Scalper and flour dresser.
1431. McDowell, C. G. — Wheels for vehicles.
1432. Platt & Richardson — Carding engines.
1434. Velluet, A. — Apparatus for making wine.
1436. Brewer, G. — Driving gear for velocipedes, boats, and other machines (*Stevens*).
1437. Thomas, J. — Sewing machines.
1440. Kirk & Brook — Jacquard harness looms.
1446. Vojácek, L. — Centrifugal pumps.
1447. Anthon, H. T. — Apparatus for moulding pulleys.
1448. Stead & Roberts — Screw propeller.
1449. Gilles, D. — Furnace for annealing plate glass.
1450. Smith, C. H. — Wool scouring machine.
1452. Crocker, S. H. — Raisin stoning machine.
1459. Wells, C., & others — Machinery for making envelopes.
1460. Jefferson, W. — Davits for lowering ships' boats.
1465. Haddan, R. — Axle boxes (*Batlle*).
1467. Marshall, C. A. — Seamless tubes.
1473. Death, E. — Steam hosiery presses.
1474. Saxby, J., & others — Interlocking apparatus for railway point and signal levers.

1st February, 1888.

1481. Rudge, J. — Machinery for barbing fish hooks.
1486. Barlow, H. B. — Stop motions for drawing frames (*Mahoney & Leigh*).
1487. Dorman, W. H. — Forming screw threads.
1489. Yuill, W. — Ironing and polishing machines.
1490. Williams, G. J. — Manufacture of grooved brackets
1494. Palmer, H. — Mules.
1498. Moore, J. — Propulsion of steam vessels.
1501. Morrin, T. F. — Steam generators.
1502. Burbery, J. S. — Boats and vessels.
1506. Montgomerie, J. — Refrigerators.
1512. McLaren, J. — Steam generators (*Despeissis*).
1515. Eissner, C. A. — Machines for cutting clay.
1517. Tooth, H. — Manufacture of pottery.
1530. Woodcock & Gwyn — Multiple drills.
1531. Abel, C. D. — Sewing machines (*Rudolph*).

2nd February, 1888.

1534. Smith, W. — Dividing double piled fabrics.
1545. Ayres, P. P. — Safety apparatus for tram engines.
1547. Ashworth & Ashworth — Carding engines.
1550. Guy, J. P. — Machine for hollow earthenware.
1551. Payne, F. — Feeding paper to printing machines.
1553. Robertson & Orchar — Finishing woven fabrics.
1555. Brown, A. F. G. — Rotary engines.
1565. Butler, S. — Shipping coal.
1572. Stephenson, G. — Machines for compressing hay.
1574. Brand & Hill — Steam boiler furnaces.
1575. Thompson, W. P. — Lifting apparatus (*Pohl*).
1579. Chadwick, P. — Hansom gigs.
1580. Berridge, I. L. — Punching machines.
1582. Martin & Blackshaw — Sizing machines.
1584. Nordenfelt, T. — Quick firing guns.
1585. Hickman & Shelton — Propulsion of canal boats.
1588. Wilson, G. — Gas engines (*McNett*).
1589. Newton, H E. — Apparatus for evaporating and cooling (*Theisen*).
1590. Nicholson, W. G. — Lessening resistance to vessels moving through water.
1592. Imray, O. — Sheet metal (*Mannesmann*).
1595. Davy, C. — Plate rolling mills.

ELECTRICITY.

27th January, 1888.

1243. Lucas & Vaughton — Electric lamp.
1254. Spink & Gauzentes — Incandescent lamps.

30th January, 1888.

1364. Martin, F. J. — Electric lighting for railway carriages.
1383. Borel & Paccaud — Electromotor.
1386. Fowler, G. — Telegraph insulators.

31st January, 1888.

1406. Turton & Turton — Electric time signals.

1st February, 1888.

1525. Solignac, L. E. — Distribution of electricity.

2nd February, 1888.

1536. Battye, J. — Telephone and telegraph.
1557. Jacob, F. — Duplex telegraphy.

CHEMISTRY.

27th January, 1888.

1270. Donald, W. — Nictric acid.

28th January, 1888.

1346. Willcox, B. — Azo dyes (*Bayer & Co.*).

30th January, 1888.

1371. Hargreaves, J., and others — Treatment of alkali waste.
1393. Hanson, J. — Sulphurous acid.

31st January, 1888.

1463. Rademann, O. — Carbolic acid.
1469. Newton, A. V. — Explosive compounds (*Nobel*).
1470. Newton, A. V. — Safety fuses (*Nobel*).
1471. Newton, A. V. — Explosives (*Nobel*).
1472. Imray, J. — Colouring matters (*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis*).

1st February, 1888.

1495. Chance & Chance — Sulphides of sodium and potassium.
1528–9. Abel, C. D. — Brewing processes (*Kiderlen, Van Leenhoff, Wernicke, Wilhelmi, & Köhlmann*).

2nd February, 1888.

1546. Wilson, J. — Sulphide of zinc.
1558. Squire, W. S. — Manufacture of yeast.
1560–1. Hake, C. N. — Chlorate of potash.
1569. Barnard, E. N. — Chlorinating ores.
1571. Newburn, J. C. — Black colour from toluidine (*La Société Jeannolle et Cie*).
1591. Abel, C. D. — Explosive compounds (*Schöneweg*).
1593. Leigh, H. H. — Colouring matters (*Williams*).

MISCELLANEOUS.

27th January, 1888.

1233. Longworth, J. — Supplying moisture to the atmosphere in weaving sheds.
1237. Jenkinson & Greaves — Hammers.
1245. Alliott & Paton — Steam disinfecting apparatus.
1246. Vering, H. — Pitch chains.
1248. Burt, H. J., & others — Metallic shell spinnings.
1251. Dronsfield, S. — Prevention of "snarls" and "lashed ends."
1252. Wood, T. — Pipe facing tool.
1253. Royston, J. — Disinfecting gas producer.
1255. Kaye, J. — Bolting doors.
1259. Royle, J. J. — Heating by steam.
1264. Shackleton, J. — Heating railway cars.
1267. Buckley, E. — Equalising the feed in scutchers.
1268. Howcroft, W. J. — Metal buckets.
1271. Tandy, H. R. — Velocipedes.
1273. Morisseau, A. — Boring and drilling tools.
1274. Settle, T. — Relieving gas retorts from pressure.
1280. Garrod, G., & others — Curtains for preventing the spread of conflagrations.
1281. Clark, A. M. — Harness (*Dax*).
1283. Lyle, J. — Improved clip or binder.
1284. Pückert, H. — Lamps (*Schwarz*).
1285. Hall & Phillips — Velocipedes.
1286. Townsend & Gould — Needles.
1287. Fletcher, R. G., and others — Velocipedes.
1288. Stevens, C. — Fire escapes.
1289. Jones, J. H. — Bottle stoppers.
1291. Stanbury, C. H. — Dark chambers for photographic purposes.

28th January, 1888.

1292. Wilson & Chittenden — Slip hook.
1294. Cliffe, J. — Asphalt composition.
1295. Harrison, R. R. — Devices for opening fan lights.
1297. Pemberton, W. — Moistening and drying warps.
1298. Parr, J. — Bicycles and tricycles.
1301. Rogers & Felmingham — Apparatus for keeping railway carriage doors closed.
1302. Campbell, S. — Fire escape.
1303. Riley, J., & others — Figured fabrics.
1304. Roberts, T. — Automatic stop block.
1307. Seage, E., & others — Fasteners for printers' tapes.
1310. Hosken, W. A. H. — Coupling for railway trucks.
1313. Redfern, W. — Valves or taps (*Howard*).
1314. Carter & Boughton — Taps for measuring spirituous liquids.
1315. Brotherhood, C. — Generating gas.
1316. Nightscales & Illingworth — Retainer bolt.
1318. Horwood, H. — Velocipedes.
1319. Wright, H. W. — Reservoirs of oil stoves.
1320. Bowen, E. — Lamp stoves.
1325. Brangwin, F. — Emptying carboys.
1326. Roberts, W. C. — Sanitary disinfecting apparatus.
1327. Bamlet, W. H. — Stopper for bottles.
1328. Dearlove & Davies — Velocipedes.
1337. Nicholls, R. — Purification of sink water.
1344. Everitt, P. — Alarm apparatus.
1349. Shaw & Sydenham — Recording the revolution of wheels.

30th January, 1888.

1352. Morgan, W. — Ironing and velouring felt hats.
1353. Wilson, J. A. — Recharging stale beer.
1354. Shingler, E. I. — Frame pulleys.
1357. Winter, T. — Immersion rollers.
1358. Washington, W. — Cardboard boxes.
1359. Thornton, J. E. — Photographic cameras.
1360. Cook, H. W. — Needles.
1366. Thomas & Thomas — Foul gas pressure indicators.
1368. Wynne, F. — Making infusions of tea.
1370. Parsons & Whitworth — Finger plates.
1373. Dittrich, J. — Chimney cowls.
1374. Mushing, E. — Velocipedes.
1376. Singer & Lea — Velocipedes.
1378. Smith & O'Donnell — Railway signalling apparatus.
1380. Moss, J. — Miners' lamps.
1388. Lübbe, L. von — Bicycle and tricycle wheel.
1389. Erfurth, O. — Support for scaffolding.
1394–5. Heaton, C. J. — Ornamental work for walls.
1398. Waquier, M. — Mincing machines.

31st January, 1888.

1399. Watkins, J. S. — Military cycles.
1401. Lloyd, A. — Pocket compasses.
1405. Leadbeater & Leadbeater — Guards or screens for machinery.
1410. Cowan, D. — Gas cooking stoves.
1412. Fraser, D. — Sights for guns.
1417. Bennett, J. F. — Brakes.
1418. Kreissig, C. H., & others — Increasing the light from burners.
1423. Smith, T. — Glass and mount cutters.
1424. Taylor, H. — Bobbins for ring spinning machines.
1428. Allison, H. J. — Nuts (*Stout & Underwood*).
1435. Carter & Aynsley — Spring to open and close doors.
1439. Martin, J. S. — Cycles.
1441. Grünbaum, H. O. A. E. — Coupling harness, railway carriages, and other objects.
1443. Boothroyd & Renouf — Velocipedes.
1444. Pert & Weston — Coating cisterns.
1445. Duffy & Fawcett — Purification of water.
1451. Hillman, W. — War cycles.
1454. Johnson, J. Y. — Tool for cutting screws (*O'Hagan*)
1456. Downes, W. J. — Spring clip pen.
1457. Gilbert, B. F. — Mop holders.
1461. Boyle, R. K. — Applying metals to metals.
1464. Rohart & Rohart — Scouring cloth.
1468. Barham, G. — Scale.
1475. Batchelor & Latch — Wire ropes.
1477. Cluse, W. — Gas burner.
1478. Tylor, J. J. — Liquid meters.
1479. Macgregor, A. — Apparatus for registering payments.

1st February, 1888.

1480. Duffy & Duffy — Window fasteners.
1484. Holmes & Sugden — Draught excluders.

4297. Hunt, B. ..... Agglomerating coal and other substances (*Couffinhal*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Gas Engines.—*H. Williams, Stockport.*—This invention relates more particularly to the type of engine known as the "Stockport" gas engine, and consists chiefly of introducing one portion of the charge of the explosive mixture of gas and air into the power cylinder at its extreme inward end, and simultaneously introducing the other part of the charge from a point in the cylinder near the head of the piston when at the extremity of its outward stroke. The object of this arrangement is to obtain a homogeneous combustible charge prior to ignition. The charge is to be ignited while compressed within the combustion chamber of the cylinder, at a point near the head of the piston when at the end of its inward stroke. The charge drawn into the charging cylinder by the outstroke of the piston is, on the instroke, compressed into a reservoir, whence different portions enter the power cylinder through separate openings. At the moment when the charge thus enters the power cylinder, the exhaust port of the cylinder is opened, and the inrushing charge expels through it the products of the previous explosion. The

Digitized by Google

charge is thus rendered homogeneous, and is ready for combustion after the piston in its return stroke has compressed it into the combustion chamber. The inventor makes three claims for the method and construction.—No. 16144. November 24th, 1887. 8*d*.

SPINNING MACHINERY.—*J. Butler & T. Howarth, Bolton.*—This invention involves the use of revolving under clearers in drawing frames and other machinery employed in spinning fibrous materials, for the purpose of removing the fluff which is gathered during the passage of the sliver. Suitable rollers are mounted in vibrating frames and are disposed below the ordinary rollers; while the frames are attached to double levers secured to the main supports of the machine. The outer ends of the levers are fitted with sliding weights in order to adjust the pressure of the under clearers against the ordinary drawing rollers. The vibrating frames are provided with a metallic roller disposed immediately below the feed roller, and with others of wood under the third and fourth drawing rollers. These clearing rollers are enclosed in an endless band of cloth, which revolves by the action of the feed roller and the pressure of the lever and frame. The cloth operates on the under side of the ordinary drawing or other rollers, clearing them of their imperfections. The inventors make two claims: For the combination of the endless band with the vibrating frames and levers; and for the general construction of the improved under clearers.—No. 6955. May 12th, 1887. 8*d*.

MULES.—*B. A. Dobson, Bolton.*—The improvements are for the purpose of effecting the changes in long lever mules in a more expeditious manner. The diagrams show the method and mechanism adopted by the inventor. Fig. 1 represents a side view, and Fig. 2 a plan of part of a self acting mule to which the invention is applied. A is the quadrant band shaft, and B is the head stock. On the shaft A is mounted a small pinion A^1 gearing with a spur wheel C, which has a scroll attached to it. A lever E is pivoted at E^1 to the head stock B; a bowl E^2 on this lever engages the scroll, and the lever E thus receives an upward and downward movement. At the end of E is a slot, into which enters a stud F^1 fixed on a slide F. This

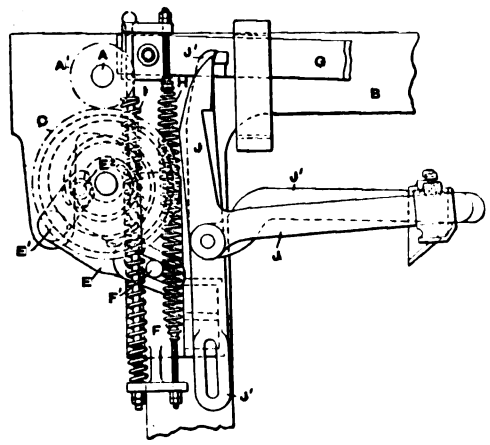

FIG. 1.

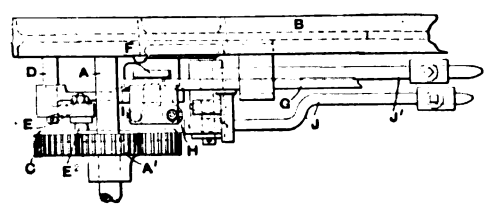
slide is free to move in a slideway fixed to the framing, and is connected by two springs H and I to the ordinary long lever G. In the outward run of the mule carriage the spring I is compressed by the revolution of A actuating the scroll, lever E, and slide F. When the catch on the latch lever J is withdrawn at the moment of making the first change, the spring I exerts its force to move the long lever G. During the inward run the quadrant shaft is reversed, and the scroll and lever draw the slide F down, and extend the spring H; so that when the carriage arrives at the end of the inward run, there is sufficient power left in H to make the third and last change when the catch on the latch lever J^1 is withdrawn. At the back end of the long lever is a stud or bowl working in a lever pivoted near



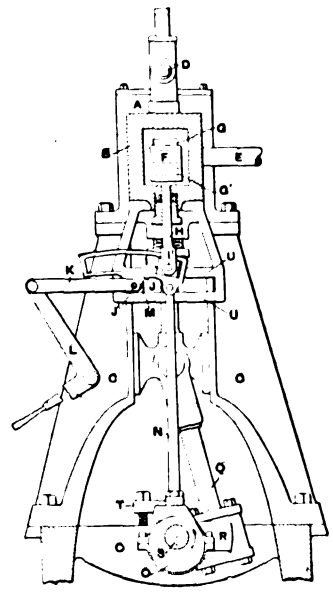


FIG. 2.

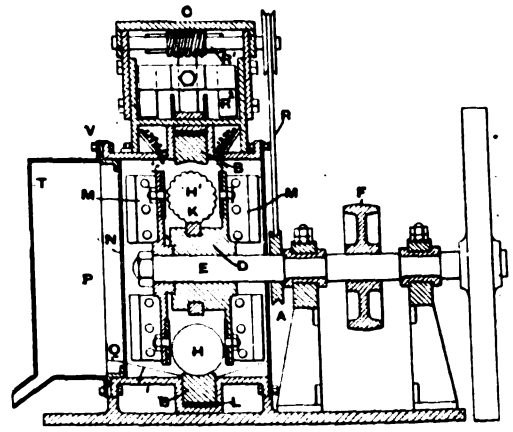
one side of the head stock. This lever is made in two parts connected together by a closed spiral spring, and one extremity of the lever has a fork which enters a groove in a catch box on the back shaft. When the first change of the long lever is made the catch box will be drawn out of gear, and the revolution of the back shaft will thus be stopped. On the second change the slot in the pivoted lever will be in a direct line with the line of motion of the stud on the long lever, and thus no further movement will be imparted to the catch box. When the third change takes place the catch box will be instantly moved back into gear and the back shaft again turned. Should the carriage be impeded in its outward course the spring will yield sufficiently to allow the catch box to slip out of gear. The inventor makes six claims for these combinations.—No. 2577. February 19th, 1887. 8*d*.

STUFFING BOXES.—*S. Griffin, Bath.*—The construction of stuffing boxes and of the metallic packing is arranged in such a manner as to reduce the friction as much as possible. A box or sleeve is arranged to contain the packing rings, and is of a diameter somewhat larger than that of the piston rod. At the bottom of the box there is a shoulder whose size is determined by a second sleeve fitting the piston rod in the usual way. A certain number of packing rings are parted at one point by a thin slot, so that when the piston rod is passed through the rings they can open and accommodate themselves to its diameter. Their tendency is to continually close on the rod and prevent the steam from escaping, and the rings are necessarily arranged so that the slots do not register with one another. In order to prevent the escape of steam between the outer edge of the rings and the inner surface of the stuffing box, the inventor introduces between each group of two or more rings a second series of rings which are bored of the same diameter as the piston rod. These rings are split, so that their tendency is to press upon the inner surface of the stuffing box, and thus the steam is prevented from escaping. The rings are held in their places by a suitable gland. The inventor makes four claims for the combination of the two sets of packing rings, and for the apparatus for adjusting them and holding them in their places.—No. 3350. March 4th, 1887. 8*d*.

VALVE GEAR.—*D. Williams, Cardiff, and W. E. Raymond, Yarmouth, Nova Scotia.*—The reversing of a steam engine is effected, according to this invention, by the employment of one eccentric only. By referring to the accompanying figure, this arrangement will be seen fitted to a vertical steam engine. The cylinder is indicated by A and the valve chest by B. The valve F controls the action of the supply ports G and G^1, and the steam and exhaust pipes are represented at D and E. At the



lower end of the valve spindle H is a jaw, in which is a block I loosely fitting on a pin I^1. Upon the upper and lower faces of the block I bears the radius link J, towards one end of which is connected the eccentric rod N. The eccentric O is set at right angles with the crank R. The radius link J is pivoted at J^1 to blocks M, which are free to slide in grooves U. A pair of drag links K are connected to the pivot pin J^1, and are operated by the hand lever L; and the blocks M are thus moved in the grooves U. In the figure the position of parts is such that the shaft S is being driven in the direction of the arrow, and the eccentric rod N and the valve spindle H ascend together as the radius link J oscillates on its pivot J^1. In order to reverse the engine the radius link is moved by means of the hand lever until the blocks M are at the opposite ends of the guides U. In this position the eccentric rod moves up and the valve spindle descends, while the shaft S revolves in the reverse direction. The inventors make three claims for the combination of parts represented in the drawings by the letters I J M U K with the other parts of the engine. No. 15915. November 19th, 1887. 6*d*.

STEAM ENGINES.—*A. J. Boult, London.* (*J. T. Case, Bristol, Connecticut, U.S.A.*)—The case of the engine is in the form of a flat thin box having a removable cap on one side. The upper end has a flange, by which it is secured overhead in a pendant position, and to serve as one of the hangers for the main line of shafting. Through the case a hollow axle extends transversely, and is divided into two longitudinal chambers, each having a port upon their upper and lower sides, opening radially. The steam pipe is connected to one chamber and the exhaust to the other. A piston surrounds this hollow axle, and is provided with a port at each end. Surrounding the piston and fitted to it is a steam box, and the piston is fitted to the sides of the steam box with ordinary packing rings. The open sides of the steam box are covered by the broad sides of the principal frame. The surface of the frame over which the steam box travels may be elevated a little over the rest. This steam box forms the cylinder of the engine, but it reciprocates instead of the piston. The steam box is connected to a crank pin on a disc mounted on a shaft by a connecting rod, which is screwed into one end of the steam box. The lower end of this rod is provided with a round stem and a shoulder. The crank pin is held between two half boxes secured to a frame having a threaded neck, through which the stem of the connecting rod passes. Within the lower part of the frame a pipe is secured which may act also as a standard. This pipe has a branch pipe at one side which is connected with a chamber provided with a central outlet pipe extending in the chamber to the level of the first motion shaft. This chamber is filled with water, which flows through the pipes and rises in the case, where its surface is covered with lubricating oil. Live steam admitted through the supply pipe passes through one port of the piston, and drives the steam box in one direction, while the exhaust steam escapes through the other port of the piston into the chamber of the hollow axle. As the crank reaches the limit of its stroke, both steam ports are closed by the solid metal between each pair of ports of the hollow axle. The further motion of the crank again opens the opposite port of the piston. The inventor makes ten claims.—No. 11915. September 2nd, 1887. 8*d*.

METAL ROOFS.—*S. Taylor, Birmingham.*—In constructing a metal covered roof the inventor uses stepped roofing sheets of zinc or galvanised iron. The steps are arranged equi-distantly and parallel with the eaves of the roof. Along each bearing edge of the roofing sheet a convex beading is made, and between the beading and the extreme edge of the sheet is a gutter, which is formed by bending upwards the extreme edge of the sheet at an obtuse angle. The combined beading and gutter is made at each bearing edge of the roofing sheets. The beading acts as a barrier to the passage of water, which the gutter conveys away. The beaded edges of adjacent sheets are not in contact, but are arranged at a short distance apart on the rafter. The opposed edges of the separated sheets are fixed to the rafter by means of a cap or fixing strip having steps in it corresponding to those in the sheets. The fixing cap between its locking edges is arched for the sake of rigidity, and in the middle of its arched part holes are made for the passage of fixing screws. The bearing edges of the sheets are thus secured firmly on the rafters, and the sheets are capable of expanding and contracting. The inventor makes five claims.—No. 4818. March 31st, 1887. 11*d*.

CARDING ENGINES.—*E. W. Wrigley & R. Patterson, Oldham.*—The object of this invention is to construct an improved indicator applicable to the flexible bends which support the ends of carding engines, so as to enable the card surface of the flats to be set with accuracy concentrically with the main cylinder. The indicator consists of a vertical finger which moves upon a pivot at one end. A short arm projects from the lower part of the finger near its pivot at right angles to the finger. This arm carries a short horizontal slot, in which works a pin in connection with the flexible bend. The flexible bends are usually mounted on three equidistant brackets. The index plate of the indicator is fixed to the central bracket, and the pin is attached to the flexible bend and works through a vertical slot in the central bracket. In the case of the two sliding brackets, the pin is fixed to the brackets, and the index plate is carried by an outer bracket secured to the framing in front of the sliding bracket. In the indicators made by the inventors each mark on the index plate represents one four-hundred-and-fiftieth part of an inch in the adjustment of the flexible bend, and thus great accuracy is attained. The inventors claim the combination of a fixed dial plate with a movable pointer actuated directly by the movement of the sliding bracket or of the flexible bend.—No. 3011. February 26th, 1887. 8*d*.

PULVERISING MACHINERY.—*J. W. Pope, London, and R. Pope, Bristol.*—The annexed figure represents a longitudinal sectional elevation of the improved machine. The outer case A is mounted on a frame, and the rotary beater D is fixed to the shaft E, which is driven by a belt passing round the pulley F. This rotary beater is cupped or chambered at its outer edges, so as to receive a number of balls H^1. These balls rest perfectly free in the chambers, and upon the rapid rotation of the beater they fly out centrifugally and revolve against the path or ring B in the casing, and thus pulverise the material which descends through the machine. In order to lessen the jar of the balls the inventors provide springs K in the base of the chambers; and behind the ring B a similar cushion L is placed. The withdrawal of the pulverised material is effected by means of a series of vanes M mounted upon the outer side of the beater. These

vanes direct the draught through a coarse mesh N and a fine gauze screen P; the coarser material which cannot pass through the second screen is returned to the machine through the outlet which is represented at Q. The machine is fitted with a hopper and a feeding apparatus which is driven by a strap R. A worm wheel R^1 is thus caused to rotate, and by these means a series of arms R^2 feeds the material in a uniform manner through holes in the bottom of the hopper. The sides of the chambers in the beater are preferably lined with hard steel plates, which may be rotated and removed in order to present fresh surfaces to wear. The part T is made removable, in order to provide access to the interior of the machine. The inventors make three claims: (1) For the combination of ring B with the rotary beater chambered to receive balls; (2) for fitting these chambers with elastic buffers; and (3) for the combination of the machine with the automatic feed, as described.—No. 1879. February 7th, 1887. 8*d*.

MANUFACTURE OF CAST STEEL.—*F. H. Lloyd, Wednesbury, and H. White, Newport, Monmouthshire.*—The inventors take highly carbonised pig iron and melt it in a cupola. A fixed converter with a silicious lining is in close proximity with the cupola, and the molten metal is allowed to flow into it. Air is blown into the converter as usual, and decarbonises the metal entirely. The metal is then run into an open hearth furnace, where it is mixed with molten metal containing the fixed amount of alloy required. The inventors make four claims for the method and apparatus designed.—No. 3670. March 10th, 1887. 6*d*.

CARDBOARD CUTTER.—*T. Furnival, E. Tudor, C. Preston, and W. Byway, Manchester.*—This improvement relates to machines for cutting out the corners in cardboard sheets used in the making of boxes. The rectangular knives which have hitherto supplied the cutting power have frequently exhibited a tendency to cross and overlap during their action. By this invention the blades are provided with projections or prolongations at their ends, so that in no position which they assume will they be altogether out of contact with each other. The possibility of their ever crossing during their up and down motion will thus be effectually precluded. The inventors make three claims for this improvement.—No. 15756. November 17th, 1887. 6*d.*

TUBULAR BOILER.—*O. Lilienthal, Berlin.*—The boiler is preferably mounted in an inclined position, and the steam generator consists of a series of bent pipes arranged in parallel planes within the outside shell. A series of walls enclose the pipes in order to form a furnace chamber and flues. The water enters the system of tubes at one end, and passes through them to the exit of steam or heated water. The flames and heated products of combustion thus come into intimate contact with the water circulating in the tubes, and the heat thereby imparted to the water causes it to rise in the tubes and sets up a continuous supply of feed water. The inventor makes two claims.—No. 16555. December 1st, 1887. 6*d.*

MACHINE FOR MAKING DOWEL PINS.—*C. F. Stewart, Norwalk, Ohio, U.S.A.*—In the manufacture of dowel pins the wood is cut into suitable lengths which are fed into the machine, where a reciprocating plunger forces the timber against the splitting knife. Hitherto a gauge has usually been rigidly attached to the bed, and the splitting knife was arranged obliquely to the line of the gauge in order to give sufficient clearance for the blank in case the wood did not split straight. If that event occurred, it was probable that the block would be turned to one side and enter the finishing die obliquely. This was the cause of many blanks being spoiled. The inventor proposes to remedy this defect by setting the splitting knife parallel with the axial line of the finishing die, and by providing a yielding guide block rabbeted along the inner lower corner to engage the blank on the rear and top sides. Springs are arranged to press the guide block downwards and forwards, by means of which the blank is always firmly held against the knife and against the bed, and made to enter straight into the finishing die. The inventor makes six claims for this improvement and for the details of its construction and arrangement of parts.—No. 13705. October 10th, 1887. 8*d.*

CASTING METALS.—*F. R. Schweiger & C. F. Mühlmann, Chemnitz, Saxony.*—The drawback connected with the casting of metals and alloys in moulds of cast iron is the difficulty experienced in expelling the gases from the molten metal in order to form a homogeneous casting without bubbles and flaws. In the usual chill and sand moulds the expanding gases drive the metal towards the walls, which yield to the pressure. The object which the inventors have in view is to provide between the molten metal and the walls of the chill a layer or coating of material which will expand on being heated. This expansion of the coating of the walls of the chill will prevent the metal being forced to the sides, and the imprisoned gases will have to escape at the free surface of the molten metal. The bubbles will thus be absent, and the number of flaws in the casting will be considerably diminished. The composition of the material which the inventors use for this purpose consists of American lard and soapstone. The chill is slightly warmed, and its interior is first coated with a layer of old American lard, the excess of which is wiped off with waste. Powdered soapstone is afterwards sprinkled over and well worked in with a soft brush. The inventors claim a chill having its inner surface coated with a layer of material adapted to expand by the introduction of molten metal for the purpose set forth.—No. 3409. March 5th, 1887. 6*d.*

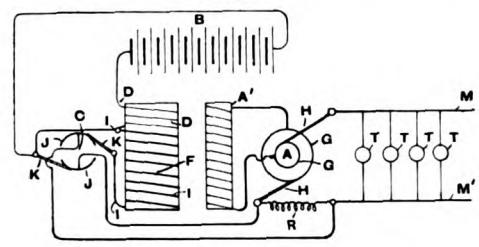
OPENING AND CLEANING COTTON.—*J. Greenhalgh, R. Greenhalgh, and J. Greenhalgh, Oldham.*—This invention relates to the class of machinery known as "Willows." The roller hitherto used for periodically projecting the material through the door at the top of the machine is dispensed with; the delivery door is mounted on a pivot at its lower edge, and is provided near its hinge with an eccentric roller for automatically widening and narrowing the passage between the hinge and cylinder; suitable guide plates are placed at the ends of the cylinder, and the flake or grid is opened and closed by the usual mechanism. When open the delivery door forms a shoot to guide the material delivered on to the lattice. In order to prevent the cotton from spreading to the sides of the cylinder, flanges are provided which have corrugations on their inner side, for the purpose of directing the cotton towards the centre of the machine. The inventors make three claims: (1) For opening and closing the passage by means of the eccentric roller; (2) for the combination with the door and roller of a sweeper or cleaner; (3) for the corrugated flanges for the purpose specified.—No. 3306. March 4th, 1887.

ELECTRICITY.

INCANDESCENT ELECTRIC LAMPS.—*A. Heintz, London.*—This invention relates to the method of manufacture of incandescent lamps of low resistance, and its object is to overcome the difficulty of introducing the straight carbon rod into the neck of the bulb. The inventor takes a glass tube whose ends may be denominated by A and B. Both ends are first drawn into taper form, then the end A is closed and a bulb is blown in the tube. The end A is opened and the end B closed, and a second bulb is blown at the A end of the tube. The end A is then opened and expanded to the form of a broad cylinder. In this state the carbon is introduced after it has been attached to the leading wires. The leading wires are held together by a stem of glass, which is subsequently attached to the neck of the bulb. The next operation is to close the opening through which the carbon has been introduced by means of a heated glass rod as is usual in glass blowing. A small glass tube is welded to the A end, which serves to exhaust the air from the lamp. The tube is afterwards sealed. The inventor makes two claims: (1) For forming the large opening opposite the neck of the lamp for the introduction of the leading wires, and (2) for the improved lamp constructed as described.—No. 16728. December 5th, 1887. 6*d.*

REGULATING DYNAMOS.—*R. P. Sellon, W. M. Mordey, and Major-General C. E. Webber, London.*—The means which the inventors make use of for the purpose of obtaining the self regulation of the electromotive force of a dynamo are illustrated in two cases in the accompanying diagrams. In Fig. 1. A^1 A and F are respectively the armature, collector, and field magnets of an alternate current generator. A commutator C is placed on the shaft, and M M^1 are main conductors connected with the collector A. The resistance R is placed on the main circuit. T T are lamps or other translating devices; and D and I are respectively the initial and correcting coils of the field magnets. The collector A is composed of two rings G connected with the terminals of the conductor on A^1. The two brushes H serve to make contact with these two rings, and the two brushes K rest on the two contact pieces of the commutator. Across some portion of the main conductor M M^1 the inventors take a shunt, the current in which is commutated at C and conducted to the initial exciting circuit I, or to a separate coil on the field F. The shunted portion of the current so obtained is for the purpose of obtaining constant potential. As this derived current is proportional to the main current, the machines may be so

FIG 1.



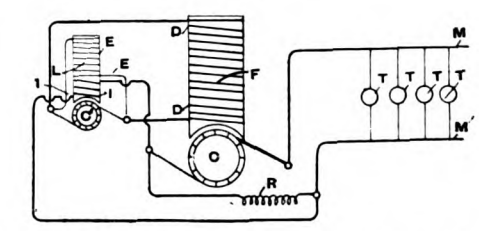


FIG. 2.

made as to maintain a constant or rising and falling difference of potential as required. For constant current working this shunted and commutated current is made to have a demagnetising effect. When a separate exciter is employed for the fields of either continuous or alternating current machines, this invention is applied in the following way: The current shunted and commutated is passed through the field coils, or through a separate coil of the fields of the exciter. The initial excitation of the main dynamo may be obtained from the separate exciter, and the correcting excitation may be produced simply by augmentation of the field current of the exciter. Fig. 2 illustrates the application of this principle to a continuous current machine. C is the commutator, and F the field magnets of the main dynamo. The fields F are excited by a current generated by a separate dynamo, of which C^1 is the commutator and L the field magnet. This exciter is in the form of a shunt machine, E being its shunt circuit. Its brushes are connected directly to the terminals D of the exciting coil of F. In addition to the shunt coil E the field is provided with a coil I, which is connected directly to the terminals of the resistance R. The coil I thus forms a portion of the main circuit, and a very small expenditure of energy is required to control the field L by the current flowing through the mains M M^1. The main current is regulated by an augmentation or diminution of the exciting current in the coil D. In constant electromotive force systems the current in I is made to strengthen the magnetisation of L; and in the case of working with constant current, the coil I weakens the effect produced by the coil E. The principle of this invention may be applied to many dynamos, and several modifications are introduced in the applications. The inventors make eleven claims.—No. 16661. December 18th, 1886. 8d.

CHEMISTRY.

HYDRATES OF BARIUM AND STRONTIUM.—*H. L. Pattinson, Felling-on-Tyne, Durham.*—In his specification of Patent No. 16989 of 1884, the inventor describes a method of manufacturing the hydrates of barium and strontium, in the course of which a liquor containing the hydrate and tersulphide was obtained. This liquor was crystallised so as to obtain the hydrate; and the crystals of the hydrate were washed with water to remove the tersulphide. In accordance with the present invention, the sulphur is removed by washing the crystals with cold water by either of the two following processes, which form the subject of this invention. In the first way a series of tanks are employed which are arranged so that the bottom of the first communicates with the top of the second, and so on, in the same way as the black ash tanks are arranged in the Leblanc soda process. The liquor from one tank, which has been almost exhausted from its sulphides, goes to the next, which has a considerable quantity of sulphide in it; the solvent powers of the water for sulphides are thus fully utilised, while with the cold water the minimum quantity of hydrate is dissolved. According to the second method, the inventor makes use of a series of cylindrical tanks, which are kept agitated mechanically. The cylinders are filled from the bottom, and are provided with a filtering arrangement at the top, through which the water passes out, leaving the solid matter behind. The water is subjected to a slight pressure when put in, and is thus made to circulate. The crystals obtained in this manner are dried by heat. The remaining liquor consists of tersulphide together with a small proportion of the hydrate. This remnant of hydrate is saved by concentrating the liquor by heat, and then cooling it down so as to separate the hydrate crystals. The inventor makes five claims for the processes and methods here described.—No. 3144. March 1st, 1887. 6*d.*

DYEING WITH ANILINE BLACK.—*F. Towlson & E. Weldon, New Basford, Nottingham.*—The object of this invention is to remedy the defects of aniline black dye—that is, its perishable colour and its lack of fastness. The material to be dyed is, according to this invention, subjected to the action of a bath composed of bichromate of potash, aniline oil, hydrochloric acid, and water. After this treatment the material is wrung out, and placed in a drying chamber and aged at a low temperature for twelve hours until it assumes a brownish black colour. On its removal from this chamber it is steamed at a low pressure for about half an hour, and then soaped and dried. In the printing process a rather different bath is used, and starch is added to the previous ingredients. The inventors make two claims for the constitution of the bath, and for the general process.—No. 3389. March 5th, 1887. 6*d.*

MISCELLANEOUS.

PACKING FOR STUFFING BOXES.—*S. Lamont & C. Lamont, Glasgow.*—The inventors employ triangular shaped packing composed of compressed canvas, with an india-rubber core placed alternately with triangular metal rings. Instead of canvas, asbestos may be used. A metal neck ring of less diameter than the stuffing box serves to keep the triangular rings in position, and also to tighten the packing when worn. The packing may be used without the metallic rings, by reversing the packing at every alternate turn. The inventors claim: (1) The triangular form of packing; (2) the adjustable neck ring; (3) the economy derived from the use of this packing, only one-half of the packing being in contact with the piston rod, every alternate turn being neutral.—No. 99. January 7th, 1887. 6*d.*

SHOE SOLE SEWING MACHINES.—*J. Albrecht, Cannstadt, Wirtemberg.*—This invention relates to the class of machines which produce double lock stitches, and its object is to sew the soles on to the shoe with two pitched threads by means of a hook needle and a shuttle. The details of the improvements are shown in Figs. 1, 2, 3, 4. The shuttle S rotates in a ring R, and is operated by a disc C and driver C^1. It has its point on its side, so that the position of the shaft A^2 is made to incline with respect to the needle bar N. The press ring H surrounding the ring R has its fulcrum in the pin H^1, and is closely guided by the cheeks H^2 and screw H^6. Two cams E^2 E^3 are inserted in the disc C and push alternately against the cheeks, thus pressing the ring downward at one time, and at another time to the left, while the spring H^5 tends to pull the ring in the contrary directions. The screw H^6 is arranged for the regulation of the length of the stitches, for when it is screwed forward the ring will not travel such a great distance. The bed plate is movable in its bearing

FIG 1.

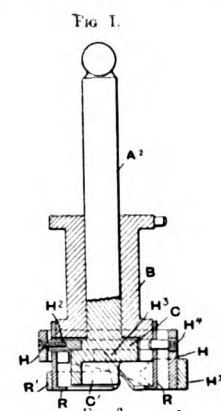

FIG. 2.

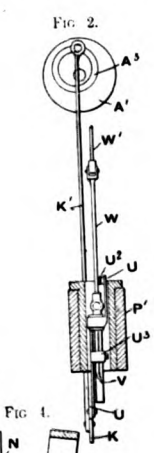

FIG 3

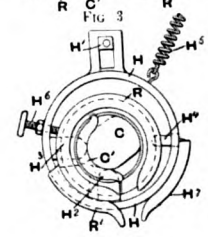

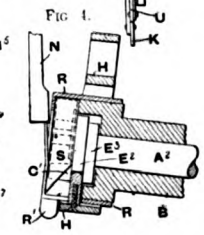

FIG 4.

P^1 (Fig. 2), which projects from the frame of the machine. The bed plate is bent so that the length of the boot shall be kept in the proper position, and that the threads shall go through the sole vertically. The thread lever K receives its reciprocating motion by the rod K^1 from the eccentric disc A^3, and carries at its front end a lever U which has a projection U^4 and a roll U^2. The rod W^1 is provided at its upper end with a small crank having an eyelet through which the thread passes on its way from the bobbin. The square rod V is somewhat twisted at its lower end, so that it may be turned by the lever as it passes up and down. This movement causes the rods W and W^1 to turn, and thus the thread is laid upon the hook of the needle. Before the thread has been drawn tight the cam E^2 has pushed against the cheek H^2, and has pressed the foot H^7 against the sole leather. The foot H^7 will be raised again by a spring attached to B. The cam E^2 presses on H^2 and moves the leather along. The cheek H^2 will then enter the indented part of E^2, and the spring H^3 draws up the presser and the latter rests on the leather. But when H^3 has sunk into the indentation of the cam E^2, the presser ring H will be drawn to the right in Fig. 3 by the spring, and the presser and shuttle will regulate themselves according to the thickness of the leather. As soon as the presser has gone back the needle will make a new stitch. The inventor makes four claims.—No. 13352. October 3rd, 1887. 8*d.*

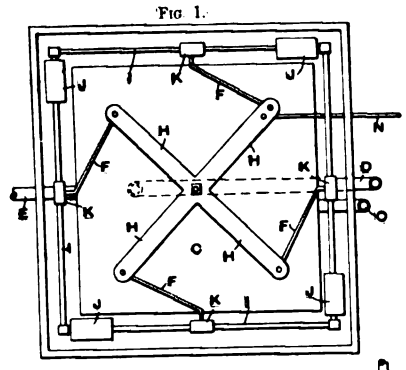
HEATING RAILWAY CARRIAGES.—*J. Langfield & R. L. Martland, Tyldesley, Lancashire.*—The heat of the fire box or smoke box of the locomotive is utilised for the heating of the railway carriages with hot air. A tube with a trumpet-shaped mouth projects in front of the engine, and during the motion of the train the air is forced down the tube. The tube leads through a chamber of cast iron, which is placed inside the fire box or smoke box of the locomotive, and the air thus heated circulates with the draught through a system of tubes, which convey it to the carriages. Under the floor of the carriages are arranged perforated pipes, which supply the hot air to the carriages, and suitable cocks are provided in the pipes for the regulation of the quantity of air admitted. The inventors claim the application of the draught caused by the motion of the train for the heating of the carriages, the air being first heated in a chamber provided in the fire box or smoke box of the locomotive.—No. 3183. March 2nd, 1887. 8*d.*

GAS GOVERNORS.—*G. Bray, Leeds.*—The object of this invention is to provide a suitable cover for the valve and flexible loaded diaphragm, which are used for governing the pressure of the issuing gas. The cover is necessarily removable in order to alter the load on the diaphragm, and to apply oil to preserve its pliability. The cover made by the inventor is hinged at one side to the case, and a lock and hasp are provided on the case for securely closing it down. This cover is thus only removable by the owner of the key. The claim is for providing a gas governor with a cover over its diaphragm, which cover is hinged to the body of the governor and secured by a hasp, as described.—No. 16716. December 5th, 1887. 6*d.*

AUTOMATICALLY EXTINGUISHING LAMPS.—*J. Y. Johnson, London. (A. Berry, Warden, Quebec.)*—The object of this invention is to provide means of automatically extinguishing the lamps in a railway collision. Compressed air is supplied to a tank under each coach from an air brake cylinder or elsewhere, and mechanism attached to the tank is arranged in such a way that a blast of air shall be admitted to the lamp to extinguish the flame in case the vehicle is telescoped or assumes an inclined position. The apparatus is shown in plan and sectional elevation in Figs. 1 & 2 herewith appended. A represents the floor of the carriage, and C is the tank which is supplied with compressed air through the tube E. The valve E¹ prevents the escape of this air. The outlet pipe is provided with a valve G, which is mounted on a spindle. This spindle is attached to the centre of the frame H, which consists of four arms. The rail rods I extend

FIG. 1.



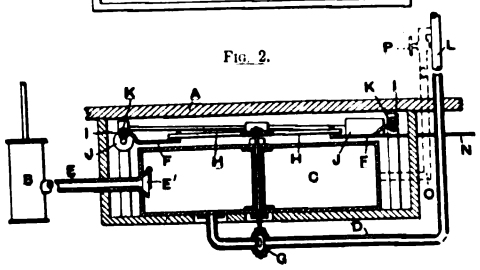


FIG. 2.

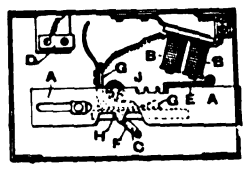
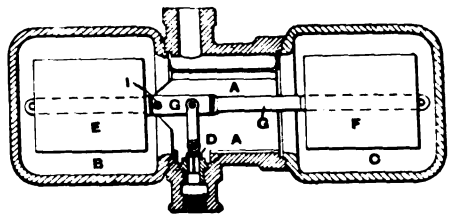


all round and outside the tank, and are carried on brackets. The weights J slide on each rail, and one or other will gravitate in the direction in which the car tips. A sleeve K also slides on each rod, and is connected by a bar F with one of the cruciform arms H. When the weight gravitates and strikes against the sleeve K, the spindle on the frame H rotates and opens the valve G. The air is thus liberated, and its discharge causes the lamps to be extinguished. The rails I are preferably slightly inclined downwards towards the normal position of the weight in order to keep the weight from accidental contact with the sleeves. The arms H have to be re-set by hand in their former position after each operation of the air and weights. N is a rod having one end attached to one of the cruciform arms H, and extending to the end of the car. In case of collision or telescoping this rod is thrust back, and thus operates the valve G in the same manner as the weights. A branch pipe O connects the tank with the distributing pipes L, and is provided with a cock P, so that by turning P the lights may be simultaneously extinguished at any time. The inventor makes six claims for these combinations, as described and illustrated.—No. 15438. November 11th, 1887. 8*d.*

INDICATING THE DIRECTION OF ROTATION OF SHAFTS.—*J. C. Ricketson, Milwaukee, U.S.A.*—This invention provides an improved method of ascertaining from a distance the direction of rotation of engine shafts. The different positions of the eccentric rods during direct or reverse rotation supply the means of operating the mechanism designed. Two electric or pneumatic push buttons are mounted on the frame of the engine, and the eccentric rods engage one of them during each revolution in one direction, and during rotation in the opposite direction the eccentric rods, being in a different position, engage the other push button. These automatic signals are communicated by an electric wire, or by a pneumatic tube, to the locality where the information is required, and one or other indicators are there actuated by one or other of the push buttons according to the direction of rotation. The inventor makes one claim.—No. 16742. December 6th, 1887. 8*d.*



GERMAN PATENT ABSTRACTS.

ELECTRIC LOCK.—*G. Straka, Gradiska.*—This invention relates to a lock with a tumbler moved by electricity. By turning the key C the key bit H presses the lever G on the contact D, thereby establishing an electric circuit in the electromagnet B

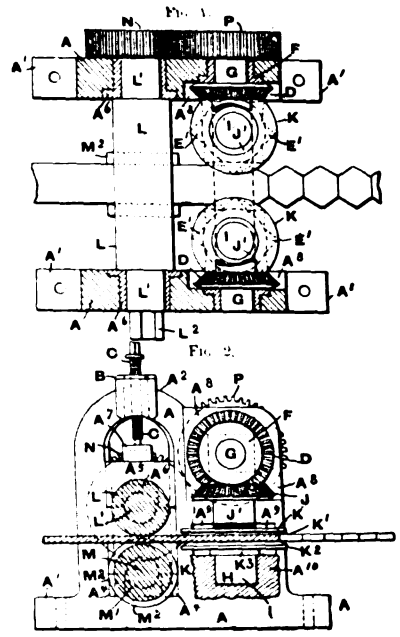
which attracts the tumbler E. The bolt A can now be moved by means of the key bit F. By doing so G is removed from the contact D by the spring J, the electric circuit is broken, and E falls into one of the notches in A, thereby locking A again.—No. 41811. June 15th, 1887.

STEAM PIPES.—*J. Kroog, Halle.*—This invention relates to the automatic removal of condensed water from steam pipes. The apparatus consists of a valve casing A and two caps B and C, which may be easily removed for cleaning. In this casing the

lever G is fixed with the fulcrum at I. G carries two solid pieces of metal E and F of equal volume but different weight, which are fixed on G in such a manner that the distances from the fulcrum I are inversely proportional to their respective specific gravities. As the water in the casing rises and partly immerses E and F, those two bodies get lighter by the weight of water displaced by them, and as E and F are of equal volume, as pointed out before, they lose an equal amount of weight; but F, acting on a longer lever than E, overbalances E, thereby opening the valve D and allowing the water to flow out.—No. 41847. May 18th, 1887.

UNITED STATES PATENT ABSTRACTS.

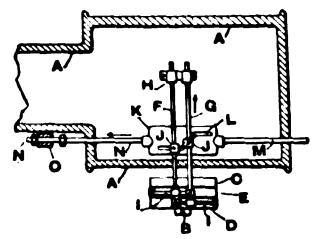
LIGHTNING ROD.—*S. R. Lawshe, Chicago.*—This rod is made in sections, and each coupling is formed of two parts, one of which has a threaded end or tenon, and the other part has a threaded cavity to receive the tenon. The length of each section is made up of one centre steel wire and two or more outside steel wires, and of a sheathing of copper arranged in such a way as to separate the steel wires from each other. The outside wires fit into collars at the end of each section, and the middle wires touch each other through the threaded tenons.—No. 375756, dated 3rd January, 1888.



PRESERVATION OF MILK.—*O. Von Roden, New York.*—The method consists of charging the milk with carbonic acid. The milk is first heated in order to expel all the air from it, and is afterwards heated in the presence of carbonic acid to a degree sufficient to destroy all germs of fermentation. After the milk has been subsequently cooled it is charged more perfectly with carbonic acid gas. A special apparatus has been designed for the carrying out of this process. The inventor makes four claims.—No. 376495, dated 17th January, 1888.

DIRECT ACTING STEAM ENGINE.—*G. W. Stewart, New York.*—The driving shaft passes vertically through the centre of the cylinder and valve chest, and has attached to it a double crank whose connecting pin slides in a slot in a metal piece, which forms the middle part of the double ended piston. The crank also has fixed to it a circularly revolving valve, which regulates the admission and exhaust of the steam. The lubrication of the moving parts is effected by placing the oil in a hollow tube, which extends the length of the vertical driving shaft, and the oil thus is admitted to the inner wall of the cylinder, and to the shaft bearings. Three claims are made.—No. 376271, dated 10th January, 1888.

TREATING LOW STEEL.—*H. A. Harvey, Orange, New Jersey.*—This invention is designed for the purpose of imparting to the metal the qualities of refined crucible steel, that is, an increased tensile strength and a greater capacity for welding. The method consists of embedding the ingots of low steel in a body of granulated wood charcoal, and depositing the whole in a crucible made preferably of plumbago. The crucible is covered so as to prevent combustion, and the furnace to whose heat the crucible is subjected is raised to a temperature exceeding that of molten cast iron. The process lasts for such a time that on removal the objects of metal exhibit clean, unblistered surfaces. The inventor makes two claims.—No. 376194, dated 10th January, 1888.



PULVERISING MACHINE.—*A. D. Searls, sen., A. D. Searls, jun., and D. C. Searls, Troy, Illinois.*—The outer case of the machine is of cylindrical form, and is mounted on a bed with the axis of the cylinder placed horizontally. A rotatable drum is disposed within, and concentrically with the outer case. On the inner peripheral surface of the drum are projections, and the radial arms of the drum are provided with lateral beaters. On the same axis is arranged a smaller cylindrical body which carries short beating arms, and the mechanism is so arranged that while the drum is rotated in one direction the short beating arms are driven in the opposite direction. This combination of beaters is designed to effect a rapid granulation of the materials. One claim is made.—No. 376112, dated 10th January, 1888.

MACHINE FOR MAKING NUTS.—*H. Harris, Reading, Pennsylvania.*—The machine is adapted for forming the nut blanks out of a continuous bar of metal. The diagrams show the essential features of the invention. Fig. 1 represents a plan of the apparatus, and Fig. 2 a sectional elevation. The frames and standards A are attached to the main frame of the machine, and carry bearings which support the rollers L M. The pinion gearing P N serves to communicate rotary motion to the shaft G, on which are fitted two bevel wheels D. These bevels gear with similar bevels J on the shafts L, which are journalled on bearings in the bed of A. On the shaft I are fixed the discs K K², and between them is the forming disc E, which has a corrugated periphery, as shown. The rollers L M are journalled

in bearings in the upright standards A, and are made adjustable by the ring M², which may be taken on or off the roller M, and by the mechanism shown at A⁷ and C. This adjustment is necessary for different thicknesses of bars of metal which are used in the process. The operation consists of introducing the bars between the rollers L M, which act as a feed, and passing them between the discs K K². The forming peripheries of E, which are placed between K K², and act in unison with each other, compress the bars into the proper form for octagonal or hexagonal nuts. The bar thus proceeds from the machine in the form shown in the diagram. The inventor makes five claims for this combination of horizontal rolls and vertical shafts carrying the forming discs.—No. 375746, dated 3rd January, 1888.

AUTOMATIC BELT SHIFTING DEVICE.—*E. R. Hyde, Springfield, Massachusetts.*—The essential features of this mechanism will be seen by reference to the accompanying diagram. The pulleys C D E are mounted on the shaft B, C and D being fast and E being loose. The belt shippers I are connected to the two shipping rods F and G, which slide in the bearings H. The guide rods M and N are fixed to the ends of the plate K and receive a longitudinal reciprocating motion from the bar O,

which is connected with one of the moving pieces. The plate K has a cam slot in it, as is shown at L in the diagram, and the pins J, mounted on the rods F G, work in the slot. The longitudinal reciprocating motion of the rods M N cause the pins J to move at right angles in the slot, and this motion is transmitted to the belt shippers I. The inventor makes one claim.—No. 375752, dated 3rd January, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE "WADDINGTON" ELECTRICAL SUBMARINE VESSEL.

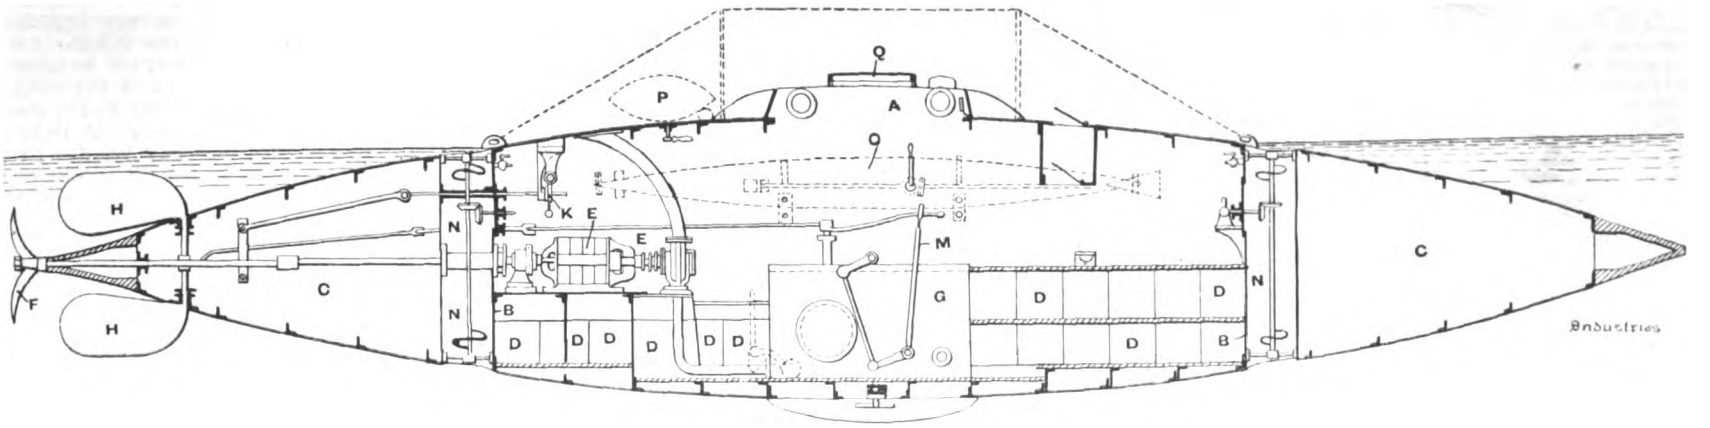

FIG. 1.—SECTIONAL ELEVATION.

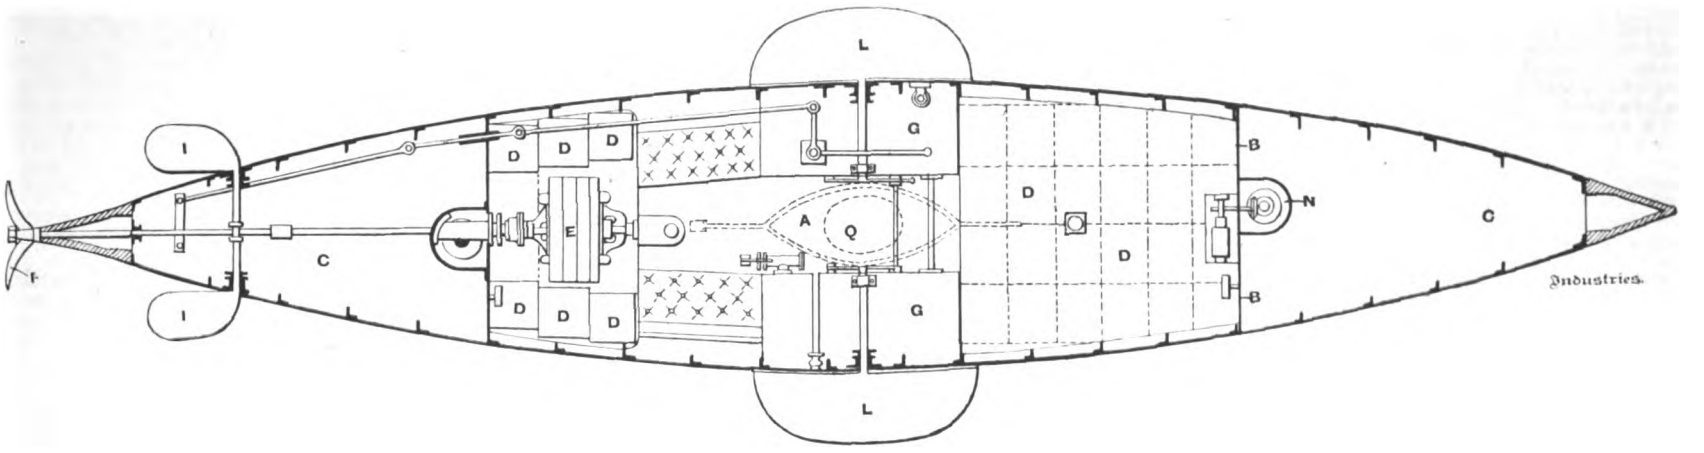

FIG. 2.—SECTIONAL PLAN.

THE "WADDINGTON" ELECTRICAL SUBMARINE VESSEL.

OUR illustrations represent a new electrical submarine vessel, designed by Mr. J. F. Waddington, of the firm of Messrs. J. F. Waddington & Co., shipbuilders and engineers, Seacombe, near Liverpool, which has recently undergone trials before representatives of the British and Foreign Governments; Count Candiani, of the Italian navy, and other gentlemen, accompanying the inventor in the vessel, below water, on various occasions. The length of this vessel is 37ft. over all, and her diameter amidships is 6ft., tapering in a curve to a point at each end. On the top of the vessel is the conning tower A, provided with ports at the sides and a water tight scuttle Q on top for entering the interior. The vessel is divided by the bulkheads B B into three compartments, of which the two end ones C C are used for storing the supply of compressed air, while the centre one is occupied by the driving, pumping, and steering apparatus. The electricity used for working the motor is stored in forty-five large accumulator cells D, which have a capacity of 660 ampère hours each, and are connected in series to an electromotor E, which drives the propeller F direct at about 750 revolutions per minute. The motor when working at full speed uses a current of about 66 ampères and 90 volts, developing 7·96 electrical horse power, which would drive the vessel for ten hours at a rate of eight miles an hour, thereby enabling the vessel to go eighty miles at full speed without replenishing the accumulators, while at half speed she would travel 110, and at slow speed 150 miles. The great advantages the inventor claims in using electricity are that when once charged the vessel is ready to start at a moment's notice; that when stopped, the motive power is not subject to waste, as in the case of steam power; and that no heat or poisonous gases are given off to pollute the air in the vessel, which is an important feature in submarine vessels; also that a small sized class of these vessels can be carried on a man-of-war's davits, ready for instant use, the same as any ordinary launch. All the levers for manœuvring the boat are arranged amidships, within easy reach of the steersman, so that he can control the movements of the vessel whilst looking out of the conning tower. A second man accompanies the steersman, to assist in case of emergency, so that the crew of the boat consists of two men only. On either side of the vessel large water ballast tanks G are provided, by filling which the buoyancy of the vessel may be reduced by several hundredweights when preparing to dive. At the after end are arranged two vertical rudders H H and two horizontal ones I I, the latter ones being used for keeping the vessel on an "even keel" when moving under water. It was found necessary to make the rudders I I act automatically, as a man might lose his presence of mind when most required. The inventor at first provided a pendulum suspended from the top of the vessel and connected to the rudders I I; but it did not answer readily enough to the action of the vessel, and he now adopts an electromotor K working into worm gearing, and arranged in such a manner that the slightest cant up or down causes the rudders to be put over to meet it, and then stop in the same manner as a steam steering gear. At each side of the vessel balanced side planes L L are provided, which may be inclined at different angles by the lever M. Close to the bulkheads at each end of the compartments C C a vertical tube, open at each end, extends right through the vessel so as to leave a clear course for the water from the vertical propellers N N, which are worked by separate motors, and may be used separately or together, as the occasion may require. At the bottom of the vessel a heavy weight is attached in such a manner that it can be released from the inside in case of an emergency, such as a sudden leak, &c. The mode of working the vessel is as follows: The water tanks G G are filled, so that only the conning tower is above water, representing only several hundredweights of buoyancy, the motor started, and a speed of say four to five miles an hour attained. Then the side planes are inclined by means of the lever M, and the vessel thereby submerged. By regulating the angle of the side planes and the speed, any reasonable depth may be maintained. If it be desirable to submerge the vessel without forward motion, only the vertical propellers are used, and any reasonable depth may be maintained by regulating their speed. These vertical propellers may also be used for regulating the depth when the vessel is moving onwards, but the side planes are considered preferable in that case. The fresh air is drawn from the two end compartments C C, and the bad air escapes through a valve as soon as the pressure inside becomes greater than that outside. But the compressed air need only be used when staying below a lengthened period, as the centre compartment contains air sufficient for two men for six hours without drawing upon the supply of compressed air. The vessel carries two locomotive torpedoes O, one on each side, secured by grips, which can be opened from the inside of the vessel. By releasing these grips the propelling motor of the torpedo is started, and it shoots ahead of the submarine vessel. A mine torpedo P is also provided for attacking any vessel at anchor with the torpedo nettings down, and which can be fired from a distance by an electric wire paid out from the submarine vessel. The dotted lines indicate portable guard rails and stanchions, which are put in place when the boat is above water—a very necessary precaution in a seaway. Mr. Waddington is still engaged in further perfecting his invention, which can be worked by compressed air as well as by electricity, and hopes at no distant date to rival the present high speed surface torpedo boats.

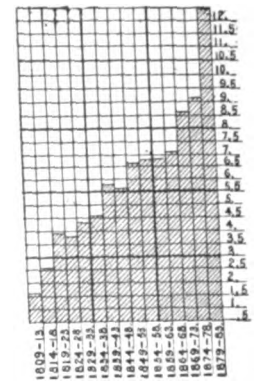
THE INSTITUTION OF CIVIL ENGINEERS.

AT the ordinary meeting on Tuesday, the 7th of February, the President, Mr. Bruce, being in the chair, the paper read was on "The Alexandra Dock, Hull," by Mr. A. C. Hurtzig, M.Inst.C.E. The Alexandra Dock was commenced on the 15th of January, 1881, and was completed and opened for traffic on the 16th of July, 1885, and during this period the works were for five months practically stopped. The dock was essentially a foreshore dock, some four-fifths of the site being below the high water mark of the Humber, and a considerable portion below the low water mark, the range of tides at springs being 22½ft. The works included a dock of 46½ acres, with two miles of dock walls from 52ft. to 62ft. in height, two large graving docks, a lock 550ft. long by 85ft. wide, a river embankment 40ft. high and 6000ft. long, the dredging of an artificial channel through the Hebbles shoal, erecting pumping machinery, the construction of sheds, and various minor works. Pending the completion of the main river embankment, the north dock wall and the graving docks were carried on under the protection of temporary reclamation banks of clay, which at the more exposed places were protected by a pitched stone face. The lock, and all the works to the westward, were included within a second reclamation, consisting of a coffer dam, a portion of the main embankment, and two transverse earth embankments. These latter were constructed with much difficulty across a foreshore consisting of mud, sometimes 27ft. in thickness, and frequently the banks made no progress for days together, owing to their sinking into the mud, and to the loss by tidal wash. The coffer dam was segmental in form, 255½ft. in radius and 461ft. long, constructed of two rows of piles 6ft. apart with clay puddle between. The piles were 50ft. to 60ft. long, and were driven about 33ft. into the ground, the toes reaching down to about 54ft. below high water mark. The dam was commenced in July, 1881, and completed in June, 1882, and contained 67,702 cub. ft. of timber. The excavations reached a total of 3,350,000 cub. yards, and in the removal of this quantity five steam navvies and two hydraulic navvies were employed, as well as hydraulic cranes and jiggers, thirty-one locomotives, and 975 waggons and trucks.

Digitized by Google

The southern portion of the dock site was covered with warp or river mud, which was stiff and sticky inshore, but softer further out; this, though drying on the surface when reclaimed, remained quite soft below for a long time. The mud varied in thickness, the greatest depth being 27ft.; and below it beds of warp, sand, gravel, clay, and peat were met with, in no definite order. The roads over this thick bed of soft mud had to be laid with two and sometimes three thicknesses of close timber and sleepers, and the passage of a locomotive over these was accompanied by a distinct undulation. A good deal of excavating was done at night by aid of electric light. The dock wall was designed to be founded 12ft. below the bottom of the dock, at which depth it was anticipated that hard clay would be found, and at the first place excavated, near the middle of the north wall, boulder clay was reached 4ft. above the required level. Proceeding eastwards, the favourable level of the clay was maintained; but westwards there was much variation, and in the last 300ft. of the western portion of the north wall the clay, after running 5ft. to 6ft. below the desired level, dipped suddenly, almost vertically; on further excavating the sand, water began to boil up all over the bottom, and the trench sides commenced to sink. A boring was put down in the trench, and it was found that an excavation 12ft. deep would have to be made to reach the clay, and to do this would have risked the collapse of the trench. Accordingly it was decided here, and for the future elsewhere, to enclose the foundations between sheet piling, tongued and grooved, and to found the walls at the designed level, unless clay could be certainly reached about 1ft. deeper. Large chalk was thrown into the enclosed space until a firm bearing was obtained, and then the concrete was deposited. The portion of the north wall on this site was finished and backed up for nearly three years before the water was let into the dock, and it showed no sign of settlement or displacement. The foundations of the lock were designed to be laid 48½ft. below high water spring tides. The side walls were built in deep trenches. In the eastern trench the clay was reached at a very suitable level; but in the western one it was 51ft. below high water spring tides. One or two slight "blows" occurred, but these were promptly dealt with in each case by placing an iron pipe in the hole, surrounding it and filling the hole with chalk rubble to the surface level of the clay, and covering with layers of Portland cement concrete in bags, upon which the foundation of the wall was laid. As the masonry was built up to near the level of the stand pipe, the water was led away from the blow holes in a horizontal pipe to a sump in the invert, thus keeping the vent open till the last moment. A far more serious "blow" occurred at the north end of this trench, and gave much trouble. The excavation over the first length at the north end was almost completed, when, without warning of any kind, the bottom of the trench suddenly began to heave, and soon water burst up in two or three places and rapidly filled up the trench, mastering the pumps. Though additional pumping power was provided, the impossibility of pumping out the water to the required level soon became apparent, not only on account of the great volume of water to be dealt with, but because of the very large amount of extremely fine silt brought up with it from below the bed of clay. This clay was thus gradually undermined, so that the sides of the timbered trench settled, and large holes appeared in the adjacent ground, forming fresh exits for the water from below, whilst the material was brought up into the trench through the main blow hole. These holes were staunched by tipping in clay puddle mixed with stable litter, straw, and bags loosely filled with Portland cement concrete. Soundings showed that the bottom of the trench was covered with a layer of silt 5½ft. thick, while a rod could be put more than 40ft. down the blow hole. The total collapse of the trench was threatened, and strong lacings were inserted, while the centre piles and struttings were partially suspended by long beams thrown across the trench. Accordingly, the pumping was reduced to the amount necessary to get in a pile foundation for the side walls at the highest possible level. The holes were filled up with chalk, and the whole area was also covered with it in order to intercept, as much as possible, the silt brought up by the water. Bearing piles were then driven between the network of temporary timbering, connected at the top by whole timber caps, on which a double thickness of elm planking was laid, forming the foundation of the inner gate recess wall and the heel post stone. The timber platform was placed as high as the level of the under side of the heel post stone, to reduce the pumping to a minimum, and thereby obviate further ill effects of the "blow." Though the difficulty was thus overcome for the time being, further trouble was anticipated at the inner gate platform, and it was proposed to excavate the foundations in small areas enclosed by half timber grooved and tongued sheeting; but after driving a short length of sheet piles, 25½ft. long, and two or three gauge piles in a longitudinal direction, some "blows" occurred at the surface, which was a little above the dock bottom, and considerable volumes of water came up. In a short time several large holes were formed, and some of the sheeting sank down and disappeared. Cast iron pipes were driven as deep as possible into the two principal springs, and in one of these the water subsequently rose 14ft. above the bottom of the dock, and remained at this level, indicating the upward pressure at this point. Clay puddle was tipped into the large holes and well trodden in, one hole alone absorbing several hundred cubic yards of puddle. The extensive area of the disturbance was manifested by the cracking and settling of the east and west dock walls at certain points, and the whole of the work at the northern end of the lock seemed in jeopardy. The continued flow of water highly charged with silt was likely to lead to further injury, whilst 14ft. of excavation remained to be accomplished for the foundations under the sill as designed. To reach the origin of the disturbance it was clearly necessary to carry the sheeting lower down; and accordingly pitch pine piles, not less than 14in. square and 50ft. long, grooved and tongued, were driven so as to enclose the principal blow holes and disturbed places, and effectually cut off the flow of water into the foundations, and the excavations were made and the foundations completed without the slightest appearance of water. The lock as finished was 550ft. long by 85ft. wide, and it had three pairs of gates, being subdivided by the middle pair into locks 325ft. and 225ft. respectively. The walls were designed to be built with rock ashlar on the face, and rubble chalk backing from the bottom of the dock up to 14ft. below the coping, and to be faced with fine ashlar above this level. A large amount was so built, but a strike of the masons whilst the work was in progress led to the substitution of 7 to 1 Portland cement concrete, faced with 5 to 1 in place of the lower ashlar and chalk. The masonry was set in lias lime hydraulic mortar, made from limestone brought from Lyme Regis and burnt upon the works. The graving docks, one 550ft. by 65ft., and the other 500ft. by 60ft., were constructed of masonry throughout. They were emptied by two centrifugal pumps of 4ft. suction. The pumps also performed a second and important duty—they were used to maintain the water level in the wet dock, and supply, as far as possible, the loss from penning. This was done by pumping from a fresh water stream, and the process was intended to obviate the necessity of dredging from the dock. The pumps could raise 14,500,000 cub. ft. of water from the stream in twenty-four hours, thus greatly benefiting the drainage of the surrounding low lying country, as well as reducing the cost of maintenance of the dock. Opposite the entrance lock, the navigable channel of the Humber, 35ft. to 40ft. deep at low water spring tides, was some 960ft. distant from the outer sill, the intervening space being the "Hebbles Shoal," consisting of hard clay and boulders. Through this shoal an artificial channel was dredged, 35 acres in extent, and the depth had been increased from between 3ft. to 6ft. down to from 12ft. to 14ft. at low water spring tides. A timber wharfing lined the sides of the trumpet entrance to the lock, and was returned for a length of 300ft. up and down the river along the Conservancy line. It was constructed in bays 10ft. apart, generally braced transversely and longitudinally, and covered with 5in. decking. The dock was well equipped with cranes, &c., and was laid out on the north side for the accommodation of the coal trade; but at present a portion only of the extensive space available was so utilised. The system of coaling was the same as that so successfully adopted at some ports in South Wales. The dock was designed and carried out by Mr. James Abernethy, Past-President Inst. C.E.

THE SCOTTISH HERRING FISHERY.



I.

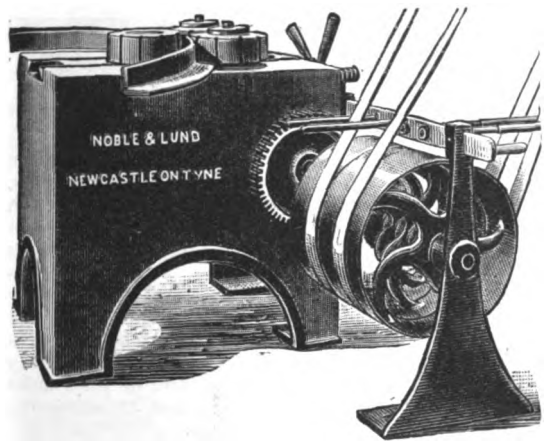
The continued prosperity of the fisheries around the Scottish seaboard is to a large extent due to the fostering care of the Fishery Board for Scotland, which was constituted by Act of Parliament in 1808. By far the most important of these, from a financial point of view, is the herring fishery, which now reaches an annual value of £1,500,000, being considerably larger than the annual rental of the seven northern counties of Scotland. Long before the Board was instituted, the fisheries were prosecuted with some degree of success, but the fishing companies which were started failed to realise expectations. The Dutch continued to fish not only on their own shores, but reaped a rich harvest on the Scottish seaboard. Jealous of their rivals, the resident Scottish fishermen began to bestir themselves to take advantage of the bountiful supply within their reach, and the Legislature seconded their efforts by helping them to find the necessary fishing tackle. Certain bounties were given by the Board of Manufactures under an Act passed in 1727; but matters were put on a proper footing in 1808, when the "British White Herring Fishery Board" was constituted. The benefits conferred on the fishing community by this Act were so marked, that at a subsequent date an Act following on the same lines was passed for Ireland; but from various causes the Irish Board did not so thoroughly work out its provisions as was done in Scotland. Among other powers vested in the Board, official brands were made on all barrels of fish which came up to a particular standard of quality and cure. These brands indicated the nature of the contents, and allowed the barrels to pass from the curing yard all over the Continent direct to the consumer, without being opened. From the carefully compiled statistics of the Board we learn that in the sea fisheries of Scotland a capital of £1,795,000 is invested in boats, nets, and other gear, while partial or permanent employment is given to about 50,000 men and boys, in addition to coopers, fish curers, and others who are largely dependent on the fisheries for employment, such as boat builders, sail and net makers.

Herrings frequent the Scottish seaboard throughout the whole year, though the greatest numbers are found during the autumn months. The winter fishing also has been of late years vigorously prosecuted; no fewer than 40,000 crans having been caught off Anstruther during 1885, while 22,184 crans were captured at Wick during the months of January, February, and March, 1886, the latter quantity, when prices were low, representing a value of £11,092. It is, however, on the summer season that the fishermen chiefly depend; this is begun on the West Coast about the middle of May, and prosecuted over the whole of the Minch till July, after which the boats move round the coast to the shores of Caithness, between which and North Sunderland the industry is vigorously carried on until September.

Although there have been considerable fluctuations from year to year, the record is one of continued progress. Beginning with a cure of 89,500 barrels in 1809, the quantity rose pretty steadily till 1884, when it reached 1,697,000 barrels. At 20s. each this represents £1,697,000, and it should be noted this is for cured fish alone—immense quantities are sent off daily to be used fresh, or as kippers. The cure of 1884, which has not since been surpassed, was larger than the total of the first ten years embraced in the Board's returns. Loud complaints were made during the years 1876 and 1877 that the herring fishery was in an unsatisfactory state, and a Commission was appointed to inquire "whether any legislative regulations would tend to promote the welfare of the fishermen engaged in the herring fishery, and to increase the supply of herrings for the benefit of the public." The best answer to the alarmists is given by the above statistics; and the Commission was no doubt right in reporting that "nothing that man has yet done, and nothing that man is likely to do, has diminished, or is likely to diminish, the general stock of herrings in the sea." The progressive character of the herring fishery is perhaps best shown by the following diagram, which gives the average cure of each five years from 1809 to 1883, and in which the figures on the right represent millions of barrels:—

Average cure of herrings in Scotland during periods of five years from 1809 to 1883.

Beginning with an average cure of 104,457 barrels for the five years 1809 to 1813, the progress has been gradual as the means of capture increased, with the exception of the five years 1844 to 1848, when there was a slight decrease, till we come to the years 1879 to 1883, when the cure averaged 1,195,787 barrels, or more than elevenfold that of the first five years. We are therefore warranted in concluding that the Scottish herring industry has attained an importance which could scarcely have been expected in the initial stages of its growth, when boats were few and bounties were given. An article of diet has thus been brought within the reach of the poor, for large quantities of herrings find their way in a fresh state daily to London and other English markets, especially in the manufacturing towns of England. From some of the Scottish fishing ports there have frequently been sent off as much as 900 tons weekly to English towns during the height of the summer fishing. During the year 1885, 139,875 crans of fresh or lightly salted herrings were sold, representing a sum of £122,034; while during 1886, 129,136 crans were disposed of, the value of which is estimated at £83,417, prices being lower in the latter year than in 1885. Before the year 1833 the bulk of the cured herrings were sent to the West Indies or Ireland, but since 1847 the demand from the latter has very greatly decreased. In 1884, when the exportation had reached its highest limit, viz., 1,185,220 barrels, Ireland and places out of Europe only took 2 per cent., the remainder all going to the Continent. Only about one-third of the total cure is reserved for home consumption. It is therefore to the Continent of Europe that the fishermen must look for their markets. Here they have powerful rivals, and in some cases almost prohibitory duties to contend against. Of late years some of the fish curers have suffered heavily in the disposal of their stock, and perhaps it may yet be necessary for the fishermen in particular districts to combine and become their own curers. This they could accomplish if the scheme were fairly taken up and judiciously worked. At present the fishermen contract with the curers for a certain number of crans per season, at a fixed price per cran, with a bounty in addition. But both the fish curers and the fishermen are beginning to see that this system cannot continue, and it has been suggested that the fish as caught should be sold at the market price of the day. There is an obvious disadvantage in this, for, when there is a large fishing, the men would be entirely at the mercy of the fish curers, who might refuse to take such a quantity of fish as might be beyond their resources. A valuable fishing might thus be entirely lost, the fish either being thrown back into the sea or used as manure; and until some radical change is made in the relations of the fishermen and fish curer the present somewhat unsatisfactory state of matters must prevail. The fishing industry has attracted to it a set of hardy men who are ever ready to prosecute their arduous calling in storm and calm along a coast line which has been described as the most dangerous in Europe, and they have been able out of their savings to invest a large capital in the purchase of boats and fishing gear.



Digitized by Google

As is well known, the herring fishery is prosecuted at night. The boats leave the harbours or fishing creeks before sunset, and make for the fishing grounds, which vary from three to 100 miles from land, the large boats now used enabling the distant fishings to be reached in good time. The most experienced fisher, when he reaches the ground, is unable to tell whether the fishing will be successful or not. One boat may have 100 crans or more, while the nearest boat may come in empty. Taking the fishing of 1886, some boats had only 50 crans for the season, while others had from 80 to 600. Fluctuations in the catch of individual boats, and in particular districts, it will readily be understood, are to be looked for. The state of the weather, the temperature of the sea, and many other circumstances come into play in the herring as in other industries. When caught and landed, the fish are without loss of time sent to the curing yards, where they are operated upon by "gutters." The gutters work with great rapidity—a gang of three women, for instance, can gut and pack during the six or seven weeks of the season 660 barrels, which means the passing through their hands of about 600,000 fish. After being properly cured in accordance with the requirements of the Board, should the fish curer desire it, on payment of a fee of 4d. the official "brand" is given to the barrels, which is simply a certificate burned on the barrels that certain conditions as to quality and cure have been complied with. There has been much controversy regarding the value of the brand, and its effect on the fishing industry. By many the operation of branding is considered an interference with trade, and it was urged that if the affixing of the brand required to be paid for it would cease to be operative. This, however, has proved to be fallacious, for, from 1859, when the fee of 4d. per barrel was imposed, instead of falling off, the brand has been in greater request than when no charge was made. The trade find it to their advantage to adopt the brand, which has yearly been used to an increasing extent. A higher price is always obtained for branded herrings than for unbranded on the Continent, as a guarantee is given for the contents of the barrels, and reliance does not require to be placed on the name which the curer may have in the market. The brand, as already stated, allows the barrels to pass unopened over the Continent, the merchants knowing well that the quality is vouched by officials who have no interest in branding herrings of inferior or doubtful quality.

(To be continued.)

IMPROVED BENDING MACHINE.

The accompanying illustration represents a bending machine constructed by Messrs. Noble & Lund, engineers and tool makers, Newcastle-on-Tyne, which is intended for bending iron or steel bars of various sections, such as angle irons, T irons, flat bars, &c., into a complete circle or part of a circle of any required diameter. The bar is passed between three rollers turned to the section of the bar operated upon, and mounted on strong spindles, which

run in bearings attached to the main frame, thereby insuring great rigidity. Each spindle is driven by a worm wheel and worm fixed inside the main framing, an arrangement which makes the machine accessible from all sides, and materially assists in preventing accidents. The worms are actuated from a shaft carrying three pulleys, as shown in the illustration. The middle pulley is keyed on to the shaft, while the other two are loose pulleys, one of which carries a crossed and the other an open belt, in the manner commonly used in planing machines. By this arrangement the machine may be instantly started, reversed, or stopped. In order to bend bars to any required diameter, one of the rollers is made adjustable by means of a screw and star handle. The machine is very compact and easily managed, and we understand that it will bend angle irons up to 3½in. by 3½in.

A NEW PNEUMATIC STONE DRESSING TOOL.

Last week we had an opportunity of inspecting a new stone dressing tool used at the works of Messrs. Farmer and Brindley, 67, Westminster Bridge Road, London, the invention of Mr. J. S. McCoy and others. The tool is a kind of rock drill in miniature, but the valve movement and internal arrangements are different. The tool consists of a gun metal cylinder in which works a loose cast iron piston. One end of the cylinder is prolonged into a nozzle through which projects a stem, into which may be inserted various forms of chisels or bits. This stem is pressed inwards by a spiral spring and receives on its inner ends the blow from the piston, which is shot backwards and forwards by air under a pressure of 40lb. per square inch. The main feature of this invention is the manner in which the air is distributed. The distributing valve is placed within the piston and with its axis at right angles to that of the piston. In the cylinder there are suitable ports by which air is admitted to one or the other end of the valve chamber, so that upon arriving at the end of its stroke the valve is shot over from one side to the other, so as to admit air through the main port to the end of the cylinder against which the piston has just arrived. We are told that in the smallest sizes the piston makes 15,000 strokes per minute, the number being ascertained by comparison with a tuning fork. There is no lubrication required for the piston, as the slight leakage which takes place between the piston and the inner surface of the cylinder practically keeps the piston floating in a thin film of air. The power required for the average size of tools which are used in stone dressing and sculpture works is about 1 h.p. per tool. In using the tool the workman supports it in his right arm and holds the front nozzle by his left hand, so as to guide the chisel or bit over the surface to be dressed. The stroke of the chisel is exceedingly short, ⅛in. or less, and as the strokes follow each other with great rapidity, the dressing of the surface is far more even than if the work were done by hand. On the back of the cylinder there is a nozzle communicating by means of an india-rubber pipe with a main supply pipe, the air being compressed by an ordinary Westinghouse reciprocating air pump. The exhaust air from the tool escapes by a hole near the back nozzle, and the tool can be stopped either by shutting off the cock on the main supply pipe or by pressing the thumb over the exhaust hole. On the occasion of our visit, the tool was shown at work on stones of various hardness, and also on wood, though we doubt that a field exists for the application of this percussive machine for working wood which can so easily be treated by rapidly revolving cutters. In all cases the work appeared to be done with great rapidity, and the dressed surface was beautifully smooth and even. The inventors also use this tool in America for caulking steam boilers and for coal getting.

EXHIBITION IN MUNICH.

An exhibition of motors and accessories for use in handicrafts is being organised in Munich by the Allgemeine Gewerbeverein of that town. It is under the patronage of Prince Luitpold of Bavaria, the Bavarian State Government, the Municipality of Munich, and the Polytechnic Society of the same town. The Exhibition will open on the 1st August, and close on the 15th October next. An international art exhibition, and a German national art exhibition will also be held this year in Munich. Thus a favourable opportunity will be given for German machine manufacturers to bring before the public their improved implements, machines, accessories, and tools. A petition has been addressed to all the German railway administrations requesting that all exhibits which remain unsold at the close of the Exhibition, should be returned to their owners without any charge being made for their carriage by the railway companies, and it is expected that this request will be granted. The construction of the exhibition buildings will be commenced on the 1st April, whilst their demolition must be completed by the 1st December. The buildings consist of two large halls in addition to various annexes. We extract the following particulars from the official programme which has been issued. The Exhibition will be supervised by the managing directors, and the site for the erection of the buildings, which is on the Isarthorplatz, has been placed at the disposal of the management by the town council of Munich. Exhibits are classed under two headings, viz.: prime movers, and machine tools and other mechanical appliances. Awards for merit will be given in the form of medals, the adjudication of which will be determined by a jury, whose formation will shortly be announced. Applications for space are to be addressed to the managing directors in Munich not later than the 1st March, and those arriving later will not be considered. A committee appointed by the management will decide as to the admission or otherwise of exhibits, and also as regards the amount of ground space to be allowed. Considering the objects of the Exhibition, heavy machinery will be entirely excluded or only accepted in the form of models. Motors exceeding 3 h.p. will as a general rule not be admitted. Persons desiring to exhibit will be informed within fourteen days after the time fixed for sending in applications as to whether their exhibits will be accepted or refused. The management consider it desirable that the performances of motors should be practically demonstrated, and trials for this purpose will be made, unless the exhibitor in his application states that he will not submit his exhibit for trial. With the exception of those articles which are manufactured in the Exhibition, and of small specialties, no exhibit will be permitted to be removed from the building without the special consent of the directors. At the same time that exhibitors receive notice that their applications for space have been granted, they will be informed how much ground space is allotted to them, the rent for which has to be paid within fourteen days after the allotment. If the payment is not duly made, or if the space granted is not occupied by the 15th July, the management reserves the right of disposing of the space as they think proper, and the exhibitor has no claim upon them. No money paid as rent will be refunded. The rent is 15s. per square metre of floor space and 10s. per square metre of wall space. Exhibits must be delivered at the Exhibition and installed at the cost of the exhibitor. The exhibits will be received before the 1st July, and the erection of working machinery must be completed by the 25th July. Special provision has been made for the transport of goods from the railway station to the exhibition buildings. Before any exhibit can be copied or photographed, the consent of the owner and directors must be obtained. The management are not responsible for any losses which may be experienced by exhibitors; but they will bear the cost of fire insurance. Exhibitors must remove their goods within eight days after the closing of the Exhibition.

RAILWAY CARRIAGE AND WAGGON WORKS.

By M. Powis Bale, M.Inst.M.E., Assoc.M.Inst.C.E.

I.

To secure in these days of excessive competition an adequate return on capital invested in wood converting works, it is necessary that such works should be very carefully arranged and managed. In arranging a saw mill, the great points to be aimed at are economy and efficiency of production. Economy in working is chiefly secured by reducing manual labour to the lowest limit by the introduction of mechanical appliances, and by having the building and its arrangements well suited to the work to be performed. In planning a railway carriage and waggon works, advantage should always be taken of the site with reference to the land or water carriage of the timber, as much money is often spent in unnecessarily hauling the timber about. The works should be so arranged that as the timber leaves the rail or water it should pass directly to the heavy machines, such as the cross-cutting machine, timber frames, or rack benches for breaking down. Its further manipulation is thus at once made easier. To illustrate this point a rough plan of a mill, designed by the author, and adapted for manufacturing railway carriages and waggons, is given (see Fig. 1). It represents a building eighty yards long by twenty yards wide. The boilers and engines, represented by 1 and 2, are arranged in a house entirely separated from the main building, and a line of rails for bringing fuel should be laid to run at the side of the boilers. The mill is divided into four sections by the rails running between them. The two sections nearest to the motive power comprise the heavy sawing machines for breaking down the logs, and sawing rough timber. These consist of cross-cut, circular, mill, and band saws. The third section includes planing, moulding, trying up, surfacing, and other machines for still further dressing and preparing the wood after it has been sawn to dimensions. The fourth section contains mortising, tenoning, scraping, sand papering, and other machines for finishing the various articles prepared in the previous sections. A sub-section may be attached to this for sawing, adzing, and boring sleepers, making treenails, compressing keys, and preparing other wood work connected with the permanent way of a railway.

It will be seen from this brief sketch that the mill is so arranged that the heavy timber enters at one end, and is gradually manipulated through the various machines till it reaches the opposite end of the building in the shape of sets of wood work for railway carriages or trucks; and mills for manufacturing any kind of wood work should be designed on this system of gradual progression. When it is once thoroughly established, and each machine has to look to another for work, a regular and economical method of manufacture is thus secured.

Sheds for storing sawn timber are not shown in the

Digitized by Google

RAILWAY CARRIAGE AND WAGGON WORKS.

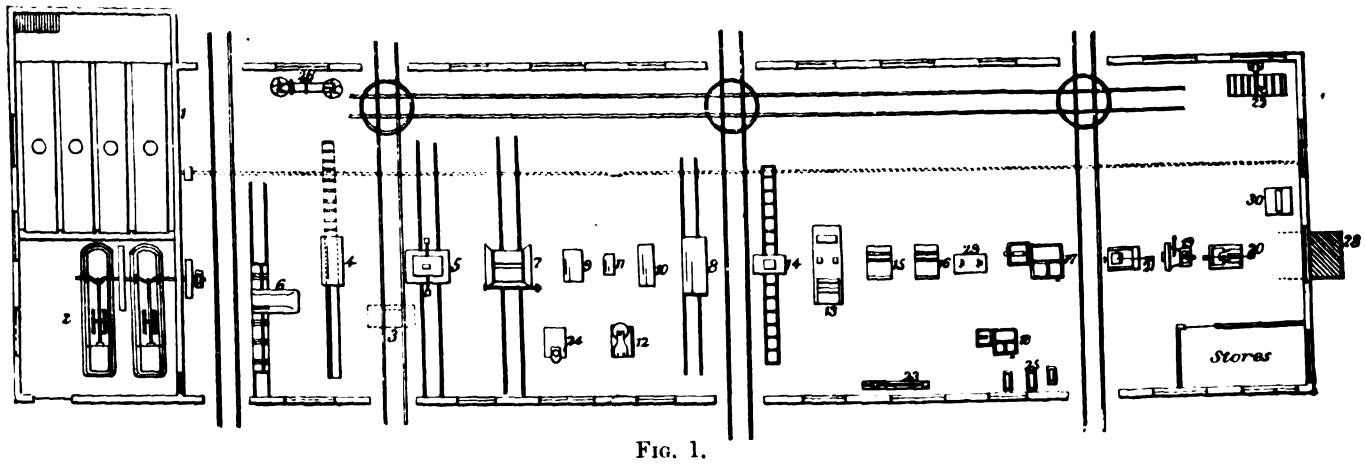


FIG. 1.

plan; but the author strongly recommends their use in preference to outdoor storing, as the wood is thus saved from unnecessary deterioration due to the action of rain, frost, or sun. In designing these sheds, care should be taken that the air is allowed to circulate freely through them. A magazine for the reception of shavings and sawdust should be attached to the mill near the boiler and engine house, which should be made as nearly fire proof as possible, and fitted with iron doors to separate them from the mill. The chimney stack base is best made of stone, laid in cement, and the engine and boiler room floors should also be cemented. All saw mill floors, whether ground or otherwise, should be of ample strength and well laid, and either a tunnel or cellar should be provided to receive the sawdust, &c., from the machines. Tramways, for bringing the wood to and from the various machines, should be laid, and an overhead traveller should traverse at least that part of the mill where the log sawing is done. Where an overhead traveller cannot be erected, Wellington travellers, running on rails and passing over each machine, are useful, as with them several logs may be lifted at the same time. Wellington travellers of about 20ft. span will usually be found sufficiently wide, and they should be fitted with both lifting and traversing gear. For fixing or turning over logs on the rack bench or saw frame, where an overhead traveller is not in use, an extremely serviceable apparatus is a travelling crab, which is usually made to run on rails attached to a beam or roof principal; the winding drum is worked by a rope, which actuates suitable worm gearing, and timber clips are attached to the end of the winding chain. Sufficient space should be left between all the machines for hand trucks to pass between them. It is important that the mill should be amply lighted both for day and night use. The electric light will, in large establishments, be found of considerable value. Should a railway run directly into the mill, it will in many cases be found advantageous in unloading the timber to have the mill floor raised a few feet above the level of the rails.

Care must be taken that the motive power is amply sufficient to drive the various machines at their full speed, as irregularity in driving through having insufficient power is detrimental to the quality of the work and output of the machines. The selection of the machinery for any particular class of manufacture is a matter of the highest importance, and, unless judiciously undertaken, the investor may find himself saddled with a lot of costly machines ill adapted to his wants. Owing to the high rate of speed it is necessary to work at, and the various strains it is subject to, first class workmanship and material is in wood working machinery more necessary than in many other kinds of machinery. In the following the author will give a few notes on what he considers the features to be desired in the construction of the various machines used in a wood works for the manufacture of railway carriages and waggons, taking the plan (Fig. 1) as a basis. No. 1 on the plan represents two pairs of Lancashire boilers, fitted with Galloway cross tubes, 35 h.p. each. The selection and proper working of a boiler must be held to be of even greater moment than the selection of the engine, and it is of the highest importance that a boiler best suited to each individual trade or manufacture should be chosen. In selecting a boiler, the chief points to be considered are what kind of water and fuel will be used; in fact, the water should in all cases be tested, and if found to contain a large percentage of sulphate of lime, or iron, or acid sulphates, no one would dream in such a case of employing a locomotive or complicated form of boiler difficult to clean, no matter what advantages may be claimed for it. In wood converting establishments, where usually large quantities of wood waste has to be burnt, Cornish or Lancashire boilers arranged with ample grate area will be found very convenient. On the plan duplicate sets of boilers are shown, an arrangement advisable in large establishments, so that in case of breakdown the whole works need not be laid idle. Each set of boilers can be used say for a month at a time, so that opportunities are given to clean or repair the boilers not in use. It will be found the best plan, unless the water is very bad, to keep the idle boilers quite full of water. Feed water heaters should be fitted, and steam pipes so arranged, that waste or other steam can be conveyed to the timber bending department, where the roofs of carriages are prepared. Steam pipes should also be laid for heating the works. Instead of slide dampers worked by hand, automatic steam worked dampers are much to be preferred, as these are entirely independent of the boiler attendant, and can be arranged to act at any desired pressure of steam, and so effect a considerable saving. Electric or other communication from the various machines to the engine room should be installed, so that the engine can be instantly stopped in case of accident.

The construction and arrangement of the main driving shafting is a factor of no little importance in economical working, but is one that as a rule does not receive the attention it deserves. Wherever the site will allow of it, the shafting should be fixed below the mill floor, as thereby the belts are out of the way, lubrication is easily seen to, and there is much less damage to the building from vibration. The shafting is best mounted in substantial standards set on brick or stone piers (Fig. 2), and so arranged that the pull of the belts is as far as possible in both directions. Steel shafting is to be preferred to iron, as it is lighter for a given amount of work, and less liable to spring. As shafting driving sawing and wood working machinery is subjected to very severe duty, and consequently to considerable and sudden strains, it is important that it should be well supported, and have a fair margin of safety. In saw mills the speed, number of pulleys, and belt tension are all considerably in excess of what is usually found in manufactories, and the shafting has to bear intermittent loads, as in the starting of heavy planing machines or rack circular saw benches. It will be found advantageous where the shafting is long to make the first length, which receives the power from the prime mover, of somewhat larger diameter than the remainder, and to place the bearings closer together. A bearing should be placed on either side of the main pulley. As regards the increase in the diameter of the first driving shaft over the following lengths, no arbitrary rule can be given; but the writer has found that if it is made about one-seventh larger than the rest, it will be amply sufficient to receive all the power transmitted. In calculating the diameter of shafting necessary to transmit a given power, it is well to err slightly on the side of strength; but care must be taken that this is not carried to excess, or considerable power may be lost daily in friction. Roughly speaking, every ton of shafting takes about 1 h.p. to move it. In erecting, the main driving shaft should be set from the driving wheel of the engine, and not from the walls of the building, as is sometimes done. Cross shafts, vertical shafts, and toothed gearing should be avoided as much as possible, as all these appliances are especially unsuited for driving high speed wood working machinery. One line of horizontal shafting should not be set vertically above another, as the driving power of the belt under these circumstances is diminished. The lengths of shafting should be arranged so that, as far as possible, the couplings should come close to the bearings. The proper distance between the bearings depends on the material of which the shaft is made, the nature of the work, the load the shaft has to carry, and the manner in which the power is taken off. A formula often used for iron shafting is as follows: $S = 4{\cdot}5\ \sqrt[3]{D^2}$ where D= diameter of shaft in inches, and S=distance of supports apart in feet; when power is taken off by pulleys between the supports, or $S = 5\ \sqrt[3]{D^2}$ when no power is taken off between the supports. In the case of saw mill shafting, the bearings, speaking generally, should be placed say 15 or 20 per cent. nearer each other than is usually done in ordinary factories. Pulleys, couplings, and toothed gearing, if used, should be placed as near the bearings as possible. All bearings should be made adjustable for wear and be arranged to pivot, as they are thus enabled to automatically adjust themselves to the exact line of the shaft in case it should be sprung or otherwise thrown out of alignment. The author, in his recent practice, has found it advantageous to considerably increase the length of bearings; the working pressure being thus distributed over a larger surface, the life of the brasses is much increased, and the amount of lubrication required is lessened. For use on saw mill shafting a bearing of three diameters in length can be recommended. All driving pulleys should combine strength with lightness, be turned true inside and out, and be perfectly in balance. As regards couplings, half lap joints with a taper of about 1in. to the foot are to be preferred to butt ends, and muff couplings to frictional or compression couplings, as

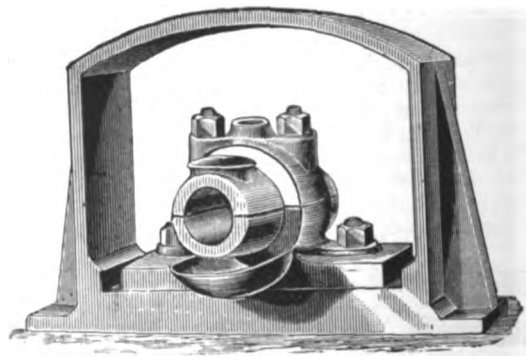

FIG. 2.

they are less liable to disarrangement. The illustration (Fig. 3) represents an improved form of muff coupling. It is made in halves, with recesses for the bolts which clamp the coupling round the shaft. This plan has the advantage of simplicity, and from the fewness of its parts it is less liable to disarrangement than some of the compression couplings in use. With the object of doing away with a number of intermediate shafts, the main shaft driving wood working machinery should be run at a tolerably high speed; 250 revolutions per minute may be accepted as a standard, and if a second or third shaft is used for driving the lighter machines, these may be speeded at 300 revolutions per minute.

In placing the various machines care must be taken that they are fixed at a dead level and on adequate foundations. The question of foundations is a factor of considerable importance in the performance of wood working machinery; more particularly that working with a reciprocating motion—such as log frames and heavy steam mortising machines. The question of getting rid of the sawdust and shavings is of some importance. If the mill is built with a tunnel or cellar the *débris* can readily be removed to a magazine near the boiler house, either by a pneumatic apparatus, by travelling bands, or even by hand. In the pneumatic apparatus the fan should be capable of creating an exhaust considerably greater than is theoretically necessary, as owing to bend friction, and in some cases back pressure, a very consider able margin is required to insure effective working. The speed of the fan should be moderate. Bends or contrac-

RAILWAY CARRIAGE AND WAGGON WORKS.

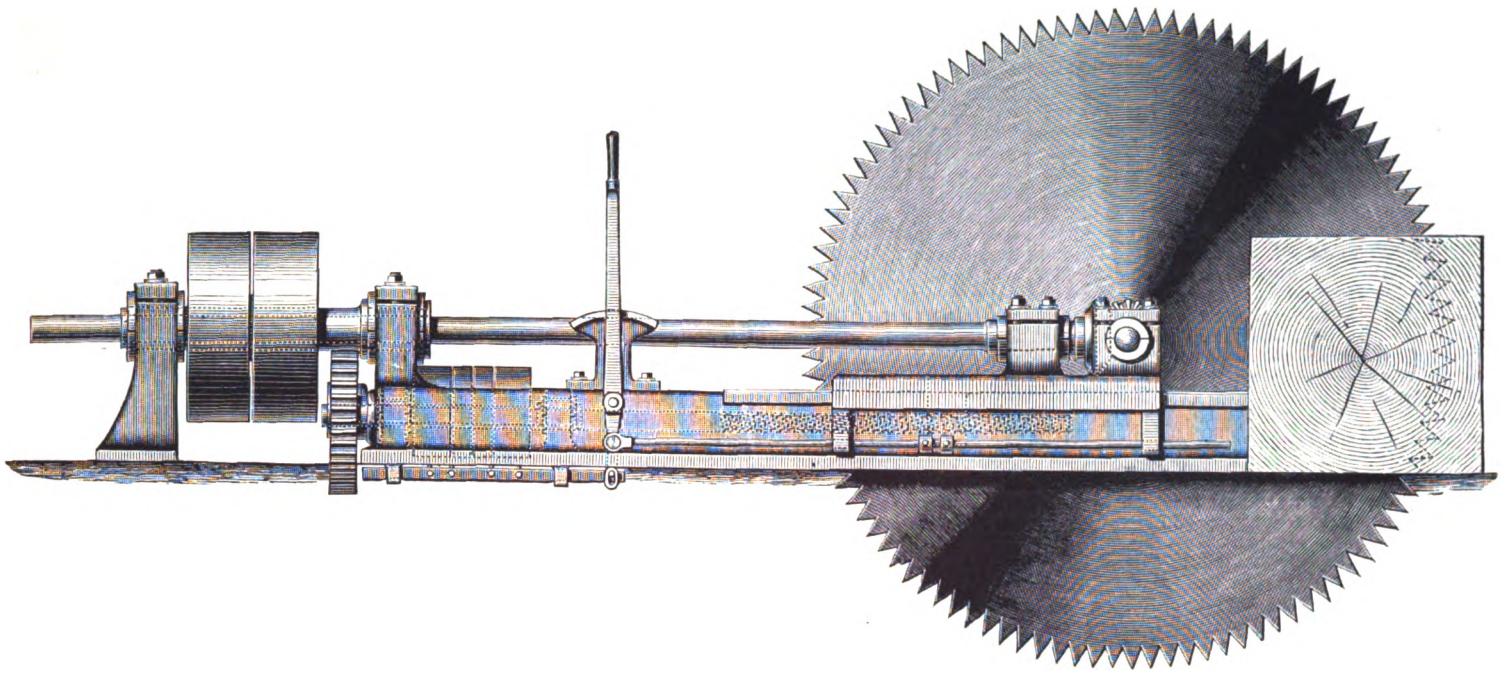

Fig. 4.

tions in the pipes should be avoided, and where necessary they should be made as gradual as possible. In joining up to the various machines care must be taken that they are tightly hooded, and in cases where cutter blocks are arranged to rise and fall they can be fitted on the telescope principle.

Returning now to the machinery shown in Fig. 1, the boilers shown at 1 are two pairs of Lancashire boilers fitted with Galloway cross tubes, 35 h.p. each; 2 is a pair of high pressure horizontal engines of 30 h.p. each; 3, circular saw cross-cutting machine (fixed below floor); 4, rack circular saw, arranged with two saws mounted one above the other, but in the same plane; 5, combined log, deal, and flitch frame, to take in logs up to 48in. diam.; 6, large band saw, with travelling table for breaking down logs, wheels 6ft. diam.; 7, horizontal single bladed saw frame, for cutting panels or crooked timber, able to take in logs 48in. diam. by 30ft. long; 8, circular saw bench arranged with roller and rope self acting feed, to carry saws up to 48in. diam.; 9, rising

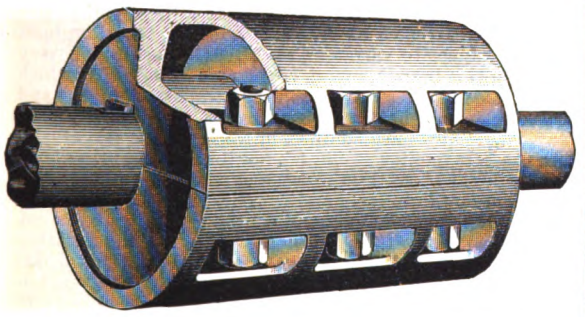

Fig. 3.

and falling spindle saw bench, to carry saws up to 36in. diam.; 10, cross-cutting circular saw bench, to carry saws up to 42in. diam.; 11, combined ripping and cross-cutting circular saw bench, to carry two saws up to 24in. diam.; 12, band saw, to cut up to 22in. deep, and having 42in. wheels; 13, four-cutter centre roller feed planing, jointing, tongueing, grooving, and moulding machine, to work wood up to 16in. wide by 6in. thick; 14, trying up and planing machine, to work up to 24in. wide by 18in. deep by 20ft. long; 15, panel planing machine, to work up to 24in. wide by 6in. thick; 16, large double tenoning and cross-cutting machine; 18, small tenoning machine; 19, slot mortising and boring machine; 20, multiple boring machine; 21, large combined steam mortising and boring machine; 22, sand papering machine; 23, large wood lathe; 24, saw sharpeners; 25, grindstones, &c.; 26, a band saw sharpening machine; 27, main shafting; 28, tunnel for shavings, running the whole length of mill; 29, double spindle irregular moulding, shaping, and recessing machine; 30, drum sand papering machine.

Additional plant for sawing sleepers and manufacturing wood work for permanent way can be fixed in a separate building or annexe. The number of machines will depend on the quantity of work required; but the plant should comprise at any rate the following: (1) Engine and boiler; (2) endless chain feed saw bench for sawing sleepers; (3) sleeper adzing and boring machine; (4) key shaping and compressing machine; (5) circular saw bench to carry saws up to 30in. diam.; (6) axe, hammer handle, and spoke dressing machine; (7) treenail turning machine; (8) horizontal slot mortising machine for fencing. When heavy timber is brought into the works, it first of all passes either to No. 3, the circular cross-cutting machine, No. 4, the rack circular saw bench, No. 5, the log and flitch frame, No. 6, band sawing machine for cutting logs, or No. 7, horizontal single bladed frame for cutting panels. If the log is of too great a length for readily converting, it is placed in any desired position on the floor over No. 3, the circular cross-cutting machine. This being set in motion, the saw rises above the floor line, and cross-cuts the log as it lies, thus at once rendering it more portable for further manipulation. To do rapid and effective work with this machine, it is important that the saw is run at the proper speed, and the teeth are kept very true and sharp. The duty of this saw—which severs or cuts the fibres of the wood crosswise—is much more severe than in an ordinary ripping saw, which cuts with the grain, the work of this latter being more of a dividing or splitting action. With woods up to a moderate degree of hardness, a speed of 10,000ft. per minute at the periphery of the saw will be found suitable. With hard woods this will require reducing. The teeth usually employed for cross-cutting purposes are known as dog, fleam, and lancet teeth. The dog tooth is illustrated in Fig. 4; it is placed perfectly upright, and the points and spaces should be the same angle, viz., 60°. This illustration represents a cross-cut circular sawing machine from the designs of Messrs. John McDowall & Sons, of Johnstone, near Glasgow. It is adapted for cross-cutting logs and trees, and consists of a strong cast iron bed, upon which is mounted a sliding carriage carrying the saw spindle. The carriage is traversed by a screw feed, actuated by toothed gearing and a set of pulleys, which receive motion from the main shaft. Motion is given to the saw spindle by means of a longitudinal shaft and pair of mitre wheels. This shaft is also driven from the main mill shaft. Another form of cross-cutting machine occasionally used consists of a straight saw, to which a horizontal reciprocating motion is given by means of a steam cylinder and piston. If it is required to cut the log into scantling, soles, buffer beams, &c., it is at once passed to the rack and other circular saw benches. Before pursuing its course further, it may be as well now to briefly consider the points of construction to be desired in the various machines, commencing with No. 4, and including the various circular saw benches. In these machines, in all cases, the main frame should be made on the "box" system, and cast in one piece. This system without doubt more readily absorbs the strains and vibrations of working than is the case when the frame is put together in sections. The face and edges of the bench should be planed. The bearings should be of ample length—at least three diameters—as the pressure and strains put upon them in working are very considerable. In all saws above 30in. diam., three bearings should be provided, one of these being placed outside the driving pulleys, to withstand the pull of the belt. In large benches, it will be found convenient to let the bearings in from the top of the bench, and fit in false plates, in preference to bolting them to the under surface of the frame. The bearings should be bored out in their places, and be made adjustable for wear. The saw spindle should be of steel, and free from seams and hard places, and fitted with a lock nut to take up end wear. The saw collars and steady pin should be very carefully made, and the latter be an easy fit, or it may throw the saw slightly out of truth. The hole in which the pin is fitted should be countersunk. The fence should be very accurately planed, arranged to bevel, and fitted with strips and fine adjustment screw, for accurately gauging the thickness of the cut. Important factors in satisfactorily working circular saw benches are the diameter and width of the pulleys employed. Many of these are undoubtedly made of too small a diameter, and too narrow on the face for the power they have to transmit, the result being over-strained and slipping belts, with rapid deterioration of bearings. The table of rack circular saw benches should be fitted with adjustable head blocks, simultaneously worked by a lever, and by means of a graduated scale any desired thickness of cut may be readily taken. By this arrangement of head blocks the timber is kept steadier, whilst under the action of the saw, than is the case with the ordinary plain table. The ordinary forms of saw benches do not require any particular notice till we come to No. 11, a combined ripping and cross-cutting circular saw bench. This machine is arranged with two saws—one for ripping and one for cross-cutting—mounted in a revolving frame. This frame is moved by means of worm gearing, worked by a hand wheel, and either saw is raised above or depressed below the table as required, the saw below the table being thrown out of motion. The fence should be arranged to bevel to an angle of 45°, and sliding plates for cross-cutting, mitreing, &c., fitted into the top of the table. This bench will be found extremely useful where there are frequent changes in the work, such as in interior carriage work, joinery, &c. It need hardly be said that the quantity and quality of work, and the power required to produce it, depend largely on the selection of the saws, and working them in what may be termed a scientific manner. For ripping purposes circular saws should have a speed of 9000ft. per minute at the periphery, and for cross-cutting about 10,000ft. It is very important also that the teeth of the saws be of the correct shape for the nature of the wood, and be equal in pitch, space, bevel, gullet, length, and set. There is an immense variety of saw teeth in use, but within the scope of these articles it is impossible to go into the question fully.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 14TH FEBRUARY, 1888.

THE IRON MARKET.—In its general situation, the iron trade has undergone further improvement. The failure of the negotiations over the renewal of the treaty with Italy has operated to depress the market; but, on the other hand, the more peaceful aspect of political affairs has acted as a stimulant. Consumers have made up their minds that prices must rise to a higher level, and they accordingly buy freely. Hence arises the activity which now characterises the business in iron, and which seems likely to continue, for besides a general revival of trade to maintain the demand, there is the prospect of an immediate resumption of building operations to quicken the trade in joists. The Paris market is animated and buoyant. The merchants are firm in their demands, their rates for bars being £5. 16s., and for joists £5. 8s. per ton. Old rails sell readily at £3. 4s. The practice, extensively indulged in by some manufacturers, of dealing directly with the consumer, gives occasion to many bitter complaints on the part of the merchants. Common plates have advanced 4s. a ton, making the present rates £7. 8s. Reports from the provinces indicate a steady improvement all round. In the Loire district, better prices are now obtained for finished iron. In the Haute-Marne, wire and wire nails are in strong demand. Chains have advanced from 1s. to 2s. a ton. Foundries are everywhere busy, and in some places are asking 4s. a ton more for castings.

THE ASSOCIATION OF FRENCH INDUSTRY.—The annual meeting of the Association of French Industry was held here last week, under the presidency of Senator Noblot. The meeting was largely attended, and some important resolutions were unanimously passed, among which the following will excite interest abroad: (1) That the State shall publish a list of all contracts made abroad, with the reasons which led to their being entered into. (2) That with a view to advance the export trade, a more judicious choice of men be for the future made to fill the post of consul. (3) That the system of temporary admission of raw and half wrought materials be regulated by law; and (4) that the railway tariffs be revised with a view to the abolition of preferential rates. The last is aimed at the import trade in English coal, which benefits by these rates.

THE SUGAR BOUNTIES QUESTION.—From trustworthy information just received, I judge that the anticipations indulged in on your side of the Channel, concerning the success of the project which forms the object of the mission of Baron Henry de Worms, are ill founded. In so far as the adhesion of France is concerned, the scheme is to be regarded as having failed. The Government dare not risk its popularity by running counter to the strong feeling against the measure which is manifesting itself among the manufacturers and the agriculturists. Letters from Berlin lead me to believe that a similar feeling exists in Germany.

AGRICULTURAL EXHIBITION IN PARIS.—The annual agricultural exhibition was held here at the beginning of the month, under the management of M. Menault. The number of exhibits was large notwithstanding the unfavourable season for a show of this character. There was a large display of agricultural machinery and a fair show of apparatus used in distilleries and dairies. The French colonies were well represented, a large number of exhibits having been sent from Algeria. Rice, tobacco, and corn from Cochin-China, Tonkin, and Annam, and sugar and rum from Réunion, Sénégal, and Guadaloupe were also exhibited. The attendance of visitors was good.

THE ELECTRICAL LABORATORY.—The inauguration of this establishment, regarding which some particulars were given in *Industries*, Vol. IV., page 91, took place on Friday last.

NEW SYSTEM OF RAILWAY CHARGES.—An agitation has been set on foot to obtain a reduction of the railway charges for commercial travellers. It is supported by some of the most influential representatives of French industry, and has been taken up by M. Dutrèsme, the Minister of Commerce, who proposes to meet the requirements of the class affected by a system of travelling cheque books, to be used in the following manner. The system is to be made applicable to all the lines in the country, and cheque books will be issued representing a certain sum per kilometre, which sum diminishes as the distance increases. A traveller buys, for example, a book of 25,000 kilometres journey. Desiring to travel from Paris, say to Lyons, he tears out one of the cheque forms and fills in the names of the stations of departure and arrival with the number of kilometres between them. He delivers this cheque to the ticket clerk, who then issues to him a ticket at the reduced rate indicated on the cheque. The tickets being paid for beforehand by purchasing the cheque book, no money passes in this transaction.

BERLIN, 13TH FEBRUARY, 1888.

THE COAL MARKET.—The firm tendency which the coal market assumed at the beginning of the year, continues to be maintained. The union of the owners of collieries producing gas coal has been prolonged to the end of the year, and at the next general assembly the question of an increase in prices will be settled. Meanwhile there is an increase in the price of coke, and every prospect of a steady trade.

THE IRON MARKET.—In the Upper Silesian district the demand for forge pig is so brisk that some furnaces are completely sold out, and have great difficulty in keeping pace with their orders. This fact is the more remarkable as nearly the whole of the production of crude iron is consumed at home. A year ago the owners of the Silesian blast furnaces had so poor an opinion of the buying capacity of the home market, that they considered the prospective decrease in their export trade an irreparable loss. The decrease was principally due to the new import tariff imposed by Russia, and has amounted during 1887 to something like 75,000 tons. Now, however, they see that their anticipations are not realised, and although the export trade has been practically abolished, the home consumption has more than made up for this loss. The increase in the demand for pig iron is partly due to the greater requirements of steel works both for the Thomas and Bessemer processes; but the principal reason is the larger demand for rolled iron. The consumption of foundry pig has not materially altered since the end of last year. The Silesian foundries making enamelled and plain ware are now erecting a common sales bureau in Gleiwitz, the organisation being on the same lines as that of the Silesian rolling mills. Tenders were recently issued by the Breslau railway management for the supply of railway tyres, and the successful firms were the following: Messrs. Borsig, 2092 waggon tyres of ingot steel, at 210s. per ton; the Laurahütte, 346 tender tyres at the same price; the Oberbilker Steel Works, 714 locomotive steel tyres of crucible steel at 225s. per ton; and the Bochum Union, sixty locomotive wheel tyres of specially selected crucible steel at 385s. per ton.

GERMAN SUGAR ABROAD.—The export sugar trade is steadily progressing, and promises soon to recover the position reached in 1884. The total exports in 1887 amounted to 12,389,238cwt., an increase of 9 per cent. on those of 1886; or an increase of 17 per cent. on those of 1885. The quantity exported in 1884exceeded 12,750,000cwt. Great Britain was last year a much larger purchaser of German sugar than in 1886. As far as can be judged at the present moment the beet harvest of 1888 promises well, and the area under beet cultivation is this year considerably greater than it was in 1887. The ruling price for contracts between the sugar factories and the farmers is now about 10s. per ton for the next harvest, and 9s. will probably be the minimum even if the harvest should prove very abundant.

TEXTILES.—Reports to hand from various centres of the weaving industry describe the position of trade as fairly satisfactory. The prices obtainable in the export trade, both in woollen and in cotton goods, are yet very low, but as the goods are mostly of inferior quality no great improvement in prices can be expected. On the other hand, however, there is a distinct improvement of prices in the home market, where the better qualities of piece goods are in strong demand, indicating the greater purchasing power of the population, which is the result of the general improvement in trade. Good orders are to hand for the spring season, especially in flannels and shirtings. The export of cloth to Italy is, however, decreasing, on account of competition from England.

THE BOILER EXPLOSION AT THE FRIEDENSHÜTTE.—As already mentioned in one of my previous letters, the Verein Deutscher Eisenhüttenleute are taking an energetic action against the attempt of boiler insurance companies to bring about an alteration in the law with regard to steam boilers fired by blast furnace gases. A few days ago the Society held a general meeting, and during the discussion on the causes of the boiler explosion it was conclusively shown by the engineer who was in charge of the works at the time, and who made a careful investigation of the boilers immediately after the explosion, that the latter was simply due to the mechanical weakness of the boilers. The plates were manufactured in 1872, that is to say, at a period when no proper and reliable tests were made before using the material. The theory that the accident was due to an explosion of blast furnace gases underneath the boilers was unanimously rejected by the Society.

VIENNA, 13TH FEBRUARY, 1888.

THE IRON MARKET.—The long expected rise in the iron market has at last taken place, and in sympathy with the better condition of trade in Germany, the prices of finished iron are advancing in Austria. The first to advance were sheets, which since the beginning of the month rose 8s. per ton. The crude iron market, however, is still depressed. Engineering shops are on the whole well employed, and as regards boiler makers and manufacturers of machine tools, work is abundant. The influence of speculation in the metal market is beginning to subside. There has been a slight rise in the price of copper, whilst tin remains firm. The prices for zinc and lead have not changed, and there is every prospect of a steady trade, provided there are no political complications to interfere with it.

TEXTILES.—Owing to the continued and strong demand for woollen piece goods of all kinds, the Moravian cloth mills are running full time, and have plenty of orders in hand for forward delivery. In yarns the markets are exceptionally firm, and unbleached cotton piece goods are accordingly advancing. As only small quantities of bleached cotton goods are imported, the quotations are also high. The market for raw silk is equally firm.

ELECTRIC LIGHTING.—The motive power required for the Jubilee Exhibition was at first estimated at 450 h.p., afterwards at 600 h.p., and now it is reckoned that it will reach 1000 h.p. The lighting of the fountains, which it is proposed to effect in the same manner as at the exhibitions in London and Manchester, has not been included in this estimate. The number of applications from persons wishing to exhibit is considerably higher than was anticipated. The Town Council of Stockerau are at present divided in opinion as to the advisability of using gas or the electric light. Sixteen councillors are in favour of the adoption of gas, and twelve advocate the employment of electricity. It has been decided to adopt gas for lighting purposes; but the necessary money for the carrying out of the project has not been granted, since the consent of more than sixteen councillors must be obtained before the money can be spent. The partisans of electricity still hope to prevail on the majority, so that the electric light may be eventually installed. In some spinning mills in the Erzgebirge the electric light has been installed. On winter mornings artificial light has to be used till 10 a.m., and in the afternoon from about 3-30 p.m. The glow lamp installation in the Court Theatre is progressing but slowly, and is not expected to be finished before the autumn. The Houses of Parliament are also to receive an electric light installation; the lighting will, however, be restricted to the legislative chambers and lobbies, the private rooms remaining lit by gas as heretofore.

STORAGE BATTERIES.—A series of experiments is now in progress at the Electro-technical Institute of this town for determining the comparative merits of the accumulators devised by Julien, Reckenzaun, and Scheneck-Farbaki. The last named cells are manufactured in Baumgarten, a suburb of Vienna, under royalty of the Electrical Power Storage Company. The local representatives of this company are Kremenesky, Mayer, & Co. In the Court Theatre scene painting is now done by electric light in order to insure the artistic effect of the colours. The current is supplied by Scheneck-Farbaki accumulators, which up to the present have proved very satisfactory.

BRUSSELS, 14TH FEBRUARY, 1888.

THE COAL MARKET.—Owing to the cold weather, large orders for household coal are being given, and as a number of blast furnaces in Belgium and Luxembourg have been blown in, coal for industrial purposes continues firm. The canals being closed by ice, it is now necessary to send coal by rail, and the old complaint as to scarcity of waggons has in consequence been revived. The competition of Belgian coal in the Mulhouse market has caused German colliery owners to demand a reduction in their railway rates, but the Belgian railways have met this move by a corresponding reduction. There is a good demand for small coking coal, coke, and briquettes.

THE METAL MARKET.—There is a still a good demand for iron, especially for girders and sheets. M. Eiffel has ordered 4000 tons of girders and sheets for Panama from La Providence works of Haumont, and it is stated that further orders for 3000 and 5000 tons offered to Belgian works have been declined, owing to the stipulated time of delivery being too short. The following orders were obtained at the adjudication of the last State railway contracts: Rolin, six third class carriages at £4,795; Verhaegen, twelve carriages of different classes at £4,781; Malines, six third class carriages at £4,795; Dyle Bacalan, twelve carriages of different classes at £4,785, and twelve composite carriages at £7,344; and La Métallurgique, twelve composite carriages at £7,164. Business is very active in this branch, owing to the number of orders which have been recently given out, and carriage builders and those who supply the material are consequently well employed. Ordinary qualities of forge pig are sold at 36s., and the best quality at 43s. 3d. per ton. These prices have been brought about by the large demand of rolling mills, and by orders from Italy and America, which have greatly reduced the stocks of pig, and caused the prices to be out of harmony with those of finished iron. This situation will, however, be altered by the increased supply of 300 tons daily, which is due to the Couillet, the Sclessin, the De Hourpes, and the D'Aloy furnaces having been just put into blast. There are throughout Belgium fifty blast furnaces, of which twenty-nine are at present at work. Of the latter, eighteen make forge pig, four foundry pig, and seven pig for conversion into steel. The daily production of forge pig is 1510 tons. At the general meeting of the Association of Bolt Makers it has been decided, in consequence of the improved condition of industry, to raise the prices of bolts.

ELECTRIC LIGHTING.—The Société Phœnix (Edison) have installed the electric light in the Ghent theatre. In addition to the arc lamps for special stage effects, there are 200 glow lamps of 10 c.p. and 140 of 20 c.p. All the lamps are of 63 volts, those of 10 c.p. requiring ½ ampère and those of 20 c.p. 1 ampère. They are all in parallel. The glow lights on the stage can be regulated, by the insertion of resistances, from dull red to a bright light in ten steps. A novelty is the employment of arc lamps instead of magnesium or lime light. When only used for a short time hand fed arc lamps are employed, but when required for a longer time the lamps are self feeding. An Edison dynamo of 70 volts and 300 ampères, running at 700 revolutions per minute, is employed. It is driven by a 45 h.p. Hertay engine working at 78 revolutions per minute. The lighting of the Molière Theatre, in this town, by the Thomson-Houston Company, has proved a great success, and the installation, which was put up under the charge of M. Admirally, the engineer of the company, is of such a

Digitized by Google

simple and economical character, as to compare favourably in cost with gas. The central electrolier in the auditorium is composed of an arc lamp of 1000 c.p., and a number of incandescent lamps of 65 c.p., which produces a very peculiar effect. Electric lighting has been introduced in the town of Mende, the generating station being placed in the cellars of the town hall.

Public Tenders.—The present manner in which State payments for contracts are made in Belgium is faulty, because settlement of accounts is often delayed for unreasonable periods. Contractors contend that if payments were always made at stated times, and if they had not to give long credit, the number of tenders would increase, and contract prices would be more moderate. M. A. Legrand, a manufacturer at Mons, has just addressed a petition to the members of the Chamber of Representatives, with a view to bring about certain reforms in the law regarding State payments, which would increase the resources of the budget. His proposal is to the effect that accounts against the State should be paid thirty days from the end of the month of delivery, with a deduction of 2 per cent. as a cash discount, and the sum thus saved by the Treasury is estimated at £80,000 per annum. This measure, if adopted, would enable small manufacturers to participate in State contracts, from which they are at present excluded in consequence of the long credit required.

DÜSSELDORF, 13th February, 1888.

The Iron Market.—The iron market is still vigorous, and consumers manifest a greater desire to buy. Political influences have had a marked effect upon business. The uncertainty which existed a fortnight ago retarded the course of affairs; but, since Prince Bismarck's speech cleared the horizon, the tone of the market has improved, and the current of business flows more freely. The strengthening of the army by the addition of 700,000 men has had a stimulating effect, for the measure will occasion the spending of not less than half a million sterling in some branches of the iron trade within the next two years. This circumstance has, for the moment, diverted men's minds from the evil effect of the current high rates on the export trade, and further advances are expected again. Manufacturers of finished iron and steel, most of whom have sufficient work in hand to keep them occupied till the end of May, are reluctant to enter into fresh contracts at present prices. In view of increasing business, they are seeking to buy pig iron for delivery in June. Hence the pig iron market has grown more active. The demand is strong for all sorts. Spiegel of 10 to 12 per cent. manganese is being freely bought at 59s.; and forge is in strong request at 53s. The blast furnace owners have now sold practically the whole of their make in the first half of the current year. Bessemer and basic steel pig are in brisk demand, but the latter is most sought after. The price is now 45s. to 45s. 6d.; Bessemer fetches about 53s. 6d. The situation is good for finished iron and steel. There is considerable activity in bars on home account, but the demand is not so strong as it was a few weeks ago. It is expected that the price will shortly be again advanced. The plate syndicate has decided on a rise of 5s. a ton in boiler and common plates, in which a very active business is being done. Sheets are less inquired after, but the demand for this class of iron is never very strong at this season of the year. Wire remains dull. The new syndicate has fixed the price of wire nails at £8. 5s. a ton.

The Wire Nail Industry.—The German wire nail industry, now brought into prominence by the syndicate, is of considerable magnitude. The works are numerous, and range in capacity from 150 tons to 14,000 tons a year. The total production exceeds that of all the rest of the world together. Assured of the home market by the protective duties imposed on foreign goods, German manufacturers have been able, thanks to cheap production, to give a good account of themselves abroad. The quantity exported in 1887 amounted to 41,303 tons, against 39,673 tons in 1886, 38,762 tons in 1885, and 38,619 tons in 1884.

The Export Trade of 1887.—German manufacturers continue to make headway against the keen competition which is encountered in most of the foreign markets, and the Customs returns for 1887 afford much encouragement. From these it appears that our foreign trade has expanded in the most desirable directions, and that the degree of expansion is in many cases large. The exports show, relatively to 1886, an increase for coal, iron, textile goods (notably cotton fabrics), glass and glass ware, paper and pulp goods, chemicals, and sugar. Machines of all kinds also show a large increase; even in sewing machines, concerning the trade in which there were so many complaints throughout the year, we see an augmentation from 6899 tons to 7347 tons. There is a slight falling off observable in the case of locomotives and portable engines.

LILLE, 14th February, 1888.

Textile Manufactures.—The general situation of the linen trade steadily improves. Last week was a period of considerable activity, woven goods having been largely bought, and stocks are now being rapidly reduced. The imports of linen cloth into the Lille district, in the month of January, amounted to 4055 kilo., and the exports to 4762 kilo.; against 7263 kilo. and 7479 kilo. respectively, in the same month of 1886. The cotton goods trade, which for a long time past has been in a depressed state, is reviving. There is a steadily growing demand for woven goods. The woollen trade is also recovering from the extraordinary fluctuations of last year. After a rise of 0·5fr. per kilo., prices are now firm at about 1fr. above the lowest rate of 1886, and 1fr. below the average of the last ten years. Thus the present situation is to be regarded as strong. Some thousands of bales of wool were bought at the London auctions last week for Roubaix-Tourcoing and Reims, chiefly the latter district, at prices from 5 to 10 per cent. above those of the last preceding sales. There is a fair inquiry for combed wool at 5fr. to 5·25fr. per kilo. for South American, and 5·75fr. to 6fr. for Australian. Cloth is steady, but the market is not animated.

Flax and Yarn Markets.—Business continues active in home grown flax, and prices remain in favour of sellers. Larger dealings have taken place in Russian flax, but prices exhibit a tendency to weakness on account of a lower rate of exchange. In yarns business has fallen off somewhat, weavers having bought much for forward delivery. Prices remain unaltered. The market is still active for jute yarns. The statistics of trade for the month of January show the quantities of raw or half manufactured textile goods imported into the Lille district, and exported therefrom, to be as follows, the quantities in brackets being those of last year: Imports of raw and scutched flax, 6,297,704 (4,609,037) kilo.; of tows, 563,361 (505,687) kilo.; of linen yarns, 109,247 (104,643) kilo.; exports of raw and scutched flax, 605,678 (251,447) kilo.; of tows, 623,443 (898,541) kilo.; of linen yarns, 149,980 (100,481) kilo.; of tow yarns, 69,554 (23,205) kilo.; and jute yarns, 7757 (3734) kilo.

The Iron Market.—Activity now forms a conspicuous feature of the iron market of this locality. Perfect unanimity prevails among the manufacturers, and the firmness of the prices of finished iron and steel resulting therefrom serves as a stimulant to consumers, who hasten to buy in anticipation of a further advance. The orders received exceed for the moment the capacity of the works, so that for some months to come there is a certainty of full employment for all. The more peaceable aspect of political affairs has had a very favourable effect upon the iron markets.

The Harmel Wool Cleaning Machine.—The Civil Tribunal of Lille has delivered final judgment in this important patent case (see *Industries*, Vol. III., page 681), and have declared, contrary to the reports of the experts, in favour of the holders of the patents, Jonathan Holden and M. Harmel. The infringers, Isaac Holden & Sons, are condemned to pay costs and damages; to give up the seventy-two machines seized at their works; and to publish the decision of the Court in five different newspapers, to be selected by the prosecutors. Thus the rights of Offermann & Harmel in this valuable machine are upheld, and there is no longer a prospect of its becoming public property before the expiration of the time the patents have yet to run.

AMSTERDAM, 14th February, 1888.

German Basalt in Holland.—The owners of German basalt quarries in the Rhine provinces are complaining of the policy of the Dutch Government, who seem determined to exclude German basalt as much as possible. Formerly this stone was much used in constructing quay walls and other works; but latterly the Dutch authorities are giving preference to the indigenous stones, and exclude German basalt from all tenders for public works on Government account. This line of action appears to be the direct consequence of the agitation got up some time ago amongst the owners of quarries and brickfields in Holland, who petitioned the States-General against the intrusion of foreign stone, where "Dutch stone would do equally well." The wisdom of the new policy of our Government officials seems doubtful. In the first place, it is well known that basalt cannot in all cases be advantageously discarded, least of all where durability is the primary condition. Besides, many basalt quarries in the Linz district and elsewhere along the Rhine belong to Dutchmen. Moreover, the Germans are now beginning to threaten retaliation, and they propose to levy an import duty on Dutch tiles, which at present, with the exception of glazed tiles, are allowed to enter duty free.

The Paris Exhibition.—At a numerously attended meeting, held in Amsterdam, it was resolved to form a society to assist intending Dutch exhibitors in every practicable way, and to advertise the advantages of this Exhibition among our manufacturers generally, so as to induce them to participate. Of course, money will be required to do this, and it is therefore proposed to start a guarantee fund. It was announced by the chairman at the last gathering that the French Government will reserve a space of 950 sq. m. for Dutch exhibits.

MADRID, 13th February, 1888.

Electric Lighting at Pamplena.—The municipality of this town invites tenders for supplying electric light for the public thoroughfares, and offers to place at the disposal of the contractor two turbines of 120 h.p. each for driving the dynamos. The turbines are situated at a distance of about half a mile from the town.

A Concession for Water Power.—A concession has been given to Señor Faura, an enterprising contractor for public works, to utilise a fall of water of the river Manzanares, at a distance of sixteen miles from Madrid. The head of water will be 90m. deep, and the quantity sufficient in any season of the year for 1000 h.p., whilst during nine months it can furnish 3000 h.p. The time allowed to carry out the works is nine years, so that the concessionaire will have plenty of time to finance his scheme.

NEW YORK, 4th February, 1888.

The Iron Market.—During the last week there has been a decided improvement in the outlook for iron, but prices remain about the same. Quotations now are 87s. 6d. to 89s. 6d. per ton for No. 1 foundry, 79s. for No. 2, and 71s. to 73s. for grey forge. The demand for bar iron is large and likely to be maintained, as a great deal of work is being contracted for in which bars will be required. Some of the long delayed orders for steel rails have now been placed, including nearly 50,000 tons for the Pennsylvania Railroad Company, and 20,000 tons for the Chicago, Burlington, and Quincy Road. The fact of these companies having placed their orders, the Pennsylvania at 131s. per ton, and the Chicago, Burlington, and Quincy at 133s., will at once bring in a number of smaller orders which have been held back under the idea that they might perhaps be placed at lower figures. The chances appear to be in favour of better prices from now until summer.

The Metal Markets.—The copper market has been active. The statement that the Tamarack Company had sold its entire output for three years at 13c. per lb. plus one-half the advance over that figure, caused considerable activity and increase of price. Sales to about 1,000,000lb. took place at 15·90c. to 15·95c. per lb. for spot, and 16·05c. to 16·10c. for delivery at end of month. The tin market has been steady but dull, prices being from 34c. to 34·10c. per lb. for March, and 33·25c. to 33·30c. for April. In lead there has been speculative buying, amounting to about 1000 tons, at prices ranging from 4·90c. to 5c. per lb. The spelter trade remains about as before, prices being from 5¼c. to 5⅜c. per lb. for Western, with very little available at the lower figures. The tendency is slightly upwards.

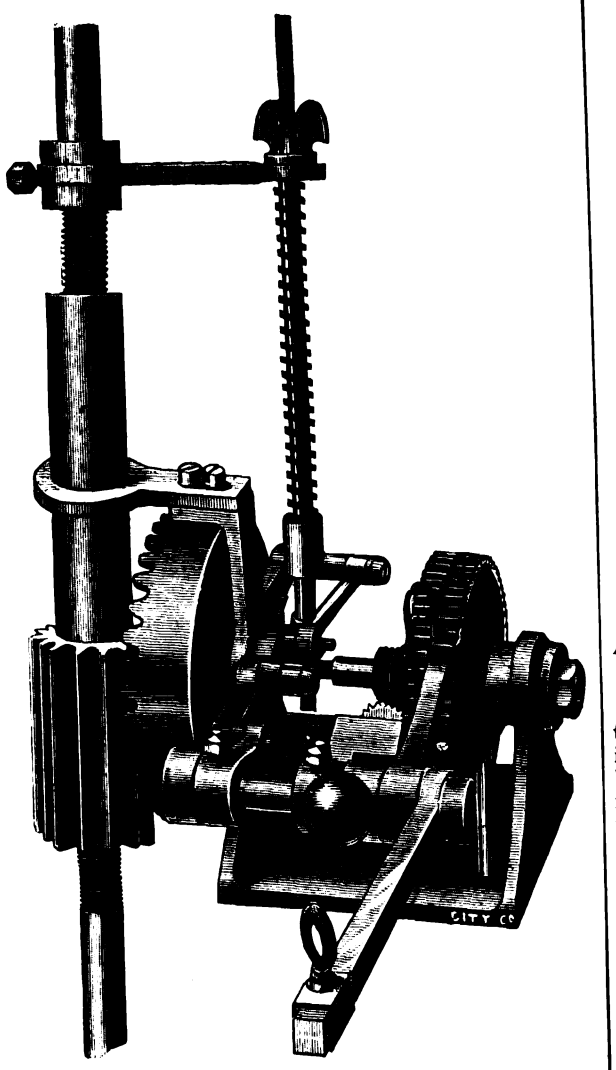
The Coal Market.—The condition of affairs among the Reading coal miners is unchanged. Most of the anthracite coal now in the market comes from the Wyoming region. Since the beginning of the year about 100,000 tons more have been mined than during the same period last year.

Railways.—The committee of general passenger agents of the trunk lines have arranged a system of through checks for baggage from New York to San Francisco. These checks will be given for baggage not exceeding the 150lb. allowed free on each first class ticket, but baggage above this weight will have to be re-checked at Missouri River Points as before. In the course of a paper read before the New York Railroad Club, by Mr. George Westinghouse, on continuous brakes on freight cars, it was stated that the adoption of air brakes on all the goods trucks in this country was merely a question of time.

PHILADELPHIA, 4th February, 1888.

Car Building.—Business generally in the car building line is good, and there is every indication that an exceptionally large number of cars will be built in this country this year. It is estimated that there will be required during 1888 not less than 200,000 cars. As about 400,000 tons of bar iron, and about 600,000 tons of cast iron will be required for these, the demand for manufactured iron for this purpose alone will be very great.

Cast Steel Guns.—Steel makers have been much interested in the casting of a steel gun for the Government at the Pittsburg Steel Casting Works. The casting on being taken from the pit was found to be perfect, as far as a superficial examination could determine. In casting it, 8¼ tons of special Bessemer steel were used, and when finished the piece will weigh 5½ tons. It will be 22ft. long, 6in. bore, and the outside diameter will vary from 23in. to 10in. The satisfactory castings that have already been made by the firm, the high tensile strength and ductility obtained, make it very likely that, if no defects are found in the casting on finishing it, it will stand the tests which it has to undergo before being accepted by the Government.



Armour Plates.—Some large armour plates have been rolled by the Spang Steel and Iron Company, for the two cruisers and a gunboat now being built by the Government. They are 7ft. wide and 10ft. long, having been rolled from a 2000lb. ingot. The same company are making the steel plates for a merchant vessel for the Oregon Improvement Company, under the inspection of the Bureau Veritas.

Beet Sugar in California.—The future of the beet sugar industry in California seems to be a promising one. A letter from San Francisco gives some facts with respect to the successful working of the factory at Alvarado, from which I learn that the company, although labouring under the disadvantage of a small plant, has conducted its operations at a profit for some years past. The land surrounding the factory will produce 3000lb. of refined sugar to the acre, and for the six seasons that the factory has been in operation, their average annual production has been 2,400,000lb. of sugar. The average cost of the refined sugar has been 5½c. per lb.; but by the introduction of improved machinery, which is now contemplated, it is expected that the cost will be reduced to 4c. per lb. The success of this factory has attracted the attention of sugar manufacturers, and several schemes are on foot to increase the number of factories. Among others, Mr. Spreckles proposes to establish factories for crude sugar in various parts of the State, the intention being to ship the crude product to San Francisco, and have all the refining done in one large refinery in that city.

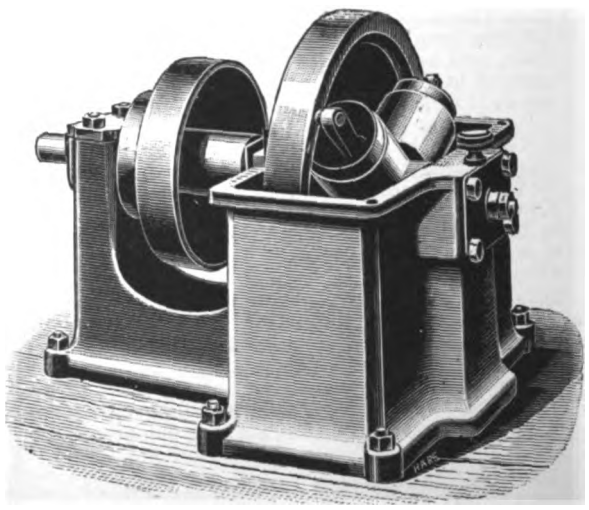
AN IMPROVED SPEED REGULATOR.

There is oftentimes a want felt by steam users and engineers for some automatic mechanism to supplement the action of the ordinary steam engine governor. As is well known, the ordinary ball governor adjusts the supply of steam to the engine through its plane of motion being raised or lowered owing to the variation of speed. It therefore follows that for any given plane of motion there is a corresponding speed, and that the desired steadiness of running of the engine may be sometimes only imperfectly obtained by the ordinary governor. With the view of remedying or nullifying this imperfect action of the main governor, several supplemental mechanisms have been adopted, which have more or less successfully overcome the difficulty of keeping the engine at a constant speed under varying conditions of load and initial pressure. The above engraving illustrates a simple mechanism of that kind, which is the invention of Mr. Wilby, and

made by Mr. James Lumb, engineer, Elland. In this arrangement the admission-valve rods of a Corliss engine, for example, would be lengthened or shortened automatically to suit the speed requirements by means of a specially arranged ratchet motion. The novelty claimed for the invention consists in the method of working the pawls in and out of gear at the required time. A rocking frame is worked by a cord or wire from some reciprocating part of the engine, and the pawls are moved in and out of gear by means of a bracket and rod connected with the governor. The regulator is fixed in a suitable position to gear with the long pinion, clearly shown in the illustration, and which is fixed to the right and left hand regulating screw shown on the left. We understand that this regulator is very sensitive, and that even a movement of $\frac{1}{16}$th of an inch in the main governor will cause it to have a compensative influence on the speed. Another advantage possessed by this regulator, and to which the inventor attaches considerable importance, is that it ceases to act altogether when the steam pressure falls below that necessary to keep the engine at its normal speed with the stop or throttle valve full open. It, however, automatically comes into action again when the pressure rises sufficiently high to give the ordinary speed. Taken altogether, this regulator seems very effective, and as it can be applied to various kinds of cut-off arrangements, and made at a reasonable cost, it is likely to come into extended use.

TYRE HEATING APPARATUS.



APPARATUS FOR HEATING, SETTING, AND REMOVING TYRES.

We are indebted for the accompanying illustration to our American contemporary *The Iron Age*. The illustration represents an apparatus recently introduced by Messrs. Pedrick & Ayer, of Philadelphia, Pa., and intended for putting on new tyres or taking off old ones without removing the wheels from the engines. We understand that with this apparatus the work is done in one-tenth of the time usually occupied, and that the paint on the wheel centres is not injured. In case of loose tyres the connecting rods need not be taken off; but in removing old tyres and putting on new ones they will, of course, be generally removed. Our illustration shows the apparatus in its stationary form; but arrangements have been made to fix the same on a truck for moving it from place to place. The engine operated upon is raised by jacks, so that the wheels will clear the rails by about 2½in., to allow the burner hoop to be placed round the tyre. This hoop is not one continuous ring of pipe, but has a little space left between the two ends, so as to allow the connecting rods to pass through. The ends are plugged up, and small studs are placed at intervals for keeping the hoop the right distance from the tyre. The apparatus consists of a furnace or generator fitted with four cast iron retorts, three of them being used for making the gas, whilst the fourth heats the air used with the gas. Besides this furnace there is provided a reservoir for holding common kerosene oil, a gauge for registering the air pressure, a needle-pointed valve for regulating the flow of oil, and an injector for mixing gas and air for burning in the hoop. The working of the apparatus is carried out in the following way: The oil reservoir is filled and the oil cock shut, so that no oil can enter the retorts, and a fire is made inside the furnace with any desired fuel. In about half an hour the retorts will be hot enough for producing gas. The hoop is then placed round the tyre and connected to the injector. Then the air pump is started, and when the pressure gauge shows a pressure of say 15lb. per square inch, the needle-pointed valve is opened and oil allowed to enter the retorts, until a rich smoke escapes from the burner holes of the hoop. Then the air cock is opened to allow air to mix with the gas, and a proper mixture of gas and air being made a torch is applied. An intensely hot blue flame will then strike the tyre and heat it up very quickly. The needle-pointed valve is fitted with a fine threaded screw, so as to allow a perfect regulation of the oil supply. The gas being used up as quickly as it is made, danger of explosion and waste of gas is prevented. When the tyre has attained the required temperature the oil supply is cut off, and the flame and generator stopped. A 4½ft. and 5ft. burner hoop are supplied with each apparatus. We understand that with the regular standard of shrinkage tyres can be taken off or put on in from four to ten minutes. The plant shown in our illustration is at work in the West Philadelphia shops of the Pennsylvania Railroad Company.

RIGG'S DOMESTIC WATER MOTOR.

It will be remembered that at the Birmingham meeting of the British Association in 1886, Mr. Arthur Rigg, of 42, Old Broad-street, E.C., showed a wooden model

of his new rotary hydraulic engine, and we illustrated the principle of this engine in our issue of the 10th September, 1886. At the Manchester meeting last year, Mr. Rigg again read a paper on the same subject, giving details of hydraulic engines which had been constructed in the interval, and were then satisfactorily running. A small domestic water motor was also exhibited. This machine we now illustrate. It is intended for use on town mains carrying water at a pressure of 60lb. per square inch, when it

Digitized by Google

will develop a power equivalent to that of two men. It weighs about 100lb., and occupies a space of 1 cub. ft. The speed can be varied from one hundred to three hundred revolutions per minute. The general construction of this machine is similar to that of the larger hydraulic engine, but the stroke is not variable. There are three cylinders radiating from and revolving independently of each other on a central stud, and water is admitted to and exhausted from each cylinder through an opening in a face at the inner end, the face sliding over the valve seat, which is at right angles to the centre of rotation. In this valve seat are the openings communicating with the inlet and exhaust pipes. The three pistons are connected to corresponding crank pins set equi-distantly on the rim of the fly wheel, the centre of rotation of which is parallel to that of the cylinders, but shifted by a distance equal to half the stroke. As the wheel revolves each piston makes thus a complete out and in stroke in each revolution. Since the stroke is fixed the quantity of water consumed per revolution is a constant, and this engine may therefore also serve the purposes of a water meter at the same time as it supplies power. The pistons and cylinders are of gun metal, so that the water is not discoloured upon issuing from the motor, and can, after its power has been given up, be used for ordinary domestic purposes.

THE WORLD'S STEAMERS.

The number of steamers existing in the world last year was estimated at 9969, of an aggregate burthen of 10,531,843 tons, and this was made up as follows: Iron steamers, 8198, of an aggregate burthen of 8,911,406 tons; steel steamers, 770, of an aggregate burthen of 1,206,962 tons; and wooden steamers, 822, of an aggregate burthen of 380,655 tons. Of the steamers afloat in 1885, 5792 were owned by the United Kingdom and its Colonies, the aggregate burthen being 6,695,871 tons. The other countries of the world owned last year the following steamers: Germany, 579; France, 509; Spain, 401; the United States, 400; Norway, 287; Russia, 212; Denmark, 200; Italy, 173; Holland, 152; Brazil, 141; Japan, 105; Greece and Turkey, 82 each; Belgium, 68; Chili and the Argentine Republic, 43 each; China and Portugal, 27 each; Hawai, 21; Mexico, 15; and miscellaneous, 50.

Lloyd's Register of Shipping.—The *Nautical Magazine* for February contains an article on this subject, in which it alludes to a statement we made to the effect that there is a movement on the Clyde for the re-construction of that body. Besides dealing with the undue predominance of the Thames and Mersey representatives on the committee, our contemporary discusses Mr. Duncan's proposal to include the load displacements as a factor in the basis of scantlings. One difficulty which presents itself to this course is, that no reliance could be placed on the statement of the shipbuilder, and that an official surveyor would not have the opportunity or the means of making an independent measurement with accuracy. The other objection which the *Nautical Magazine* suggests is, that the policy of the shipbuilder would be to have a minimum displacement, and possibly it might be found that the declared load line would be less than that allowed at Lloyd's, while in loading at a foreign port there would be no scruple about exceeding the supposed load line. In preference to Mr. Duncan's proposal our contemporary suggests that it would be simpler to alter one of the existing factors of the basis of scantlings, by substituting the actual mean girth of the hull for the girth of the midship section.

Professor Ryan, of the University College, Bristol, delivered an address at the distribution of prizes at the Science and Art Schools, Newport, Monmouthshire, on the 13th inst. He referred in complimentary terms to the disinterested action of the men who created that school fourteen years ago, and who were energetic and far-seeing enough to solve the problem of technical education for their town at a time when the British Government were thinking about appointing a Royal Commission, which he characterised as the unfailing resource of procrastination. Their pupils were now spread far and wide, producing an effect on engineering industry, not only in England, but in her remote Colonies. They had, he might say, turned out a generation of engineers, while the Government had not got beyond a prospective Bill. Professor Ryan went on to show how science and art enhanced the value of raw material. Science has more than answered the extravagant hope of the alchemist, and surpassed the fabled power of Crœsus. Science and art can transmute ignoble metal into objects worth more than their weight in gold. If a Crœsus should touch the balance spring of a modern watch, it would lose two-thirds of its market value. Again, a single lens for a telescope may be worth more than £1,000 sterling. He urged them, therefore, not to seek after the gold of the earth, like the ancients, but to mine in the unexhausted and inexhaustible fields of science and art, and to rely on the potentiality of wealth and power that existed in their own brains and in the cunning of their own hands. He thought it high time that Monmouthshire and South Wales should prepare for the inevitable struggle that is close at hand. It was a frequent boast that they were the largest exporters in the world of finished iron and steel; but they were scarcely yet alive to the fact that the conditions of that trade were gradually changing—that the balance was going against them. Their supremacy depended on coal and the seaboard. These they still retained; but science had reduced the expenditure of coal to less than one ton per ton of steel produced in many cases, and, consequently, to much less than one ton per ton of ore treated. On this account it would be cheaper to take the coal to the ore than to carry ore to the coal. Up to the middle of the last century, iron works were situated in the neighbourhood of the ore, the fuel being furnished by adjacent works. By the beginning of this century, the industry had shifted to the coal fields, and there it must have remained so long as it took eight tons of coal to produce one ton of iron. The knowledge and ingenuity of Neilson and others had, however, effected vast economies, until now industrial inertia seemed to be the chief reason why the steel works still stick to the coal fields. Up to 1860, South Wales smelted much of the ore raised in the Barrow district, but increased facilities for getting coal from Durham and elsewhere enabled the ore to be profitably worked on the spot, and South Wales turned to the North of Spain for supplies. The Spaniards in their turn have now found it profitable to get our coal and make steel rails for themselves. In course of time the foreign manufacturers will be protected, and we shall be practically shut out of Spain and Italy. The tendency of science is to minimise natural advantages; it abridges space and time, and alters the effect of original distributions. Welshmen have, however, shown that they can take advantage of it, as they did when they substituted Bessemer plant and steel rail mills for the old iron ones. Engineering and metallurgical industries have reached such a pitch of perfection that they cannot any longer be improved by chance experiment. Inasmuch as the future was with the scientifically trained engineer and metallurgist, Professor Ryan was glad to see that the subject of technical education was engaging the attention of the University College authorities at Cardiff.

Notices of Meetings.

THIS WEEK.

The South Staffordshire Institute of Iron and Steel Works' Managers.—Saturday, 18th February. Ordinary meeting. Paper to be read on "Some Curiosities of Iron Manufacture," by Mr. A. E. Tucker, F.I.C., F.C.S.

NEXT WEEK.

Society of Arts.—Monday, 20th February, 8 p.m. Cantor lecture on "Yeast: its Morphology and Culture," by Mr. A. Gordon Salamon, F.I.C., F.C.S.—Wednesday, 22nd February, 8 p.m. Paper to be read on "The Technical Education Bill," by Mr. Swire Smith.

Society of Chemical Industry.—Monday, 20th February, 8 p.m. Papers to be read on "The Bromine Absorption of Mineral Oils," by Mr. James B. McArthur, and "Note on Camphor Oil and Oil of Sunflower," by Mr. C. T. Kingsett.

Royal Institution of British Architects.—Monday, 20th February. Ordinary meeting. Nomination of candidates. Paper and discussion.

Institution of Civil Engineers.—Tuesday, 21st February, 8 p.m. Ordinary meeting. Discussion upon the Paper by Mr. Pierce, jun., on "The Economic Use of the Plane Table in Topographical Surveying," and Papers to be read, time permitting, on "Manganese in its Application to Metallurgy," and "Some Novel Properties of Iron and Manganese," by Mr. R. A. Hadfield, Assoc.M.Inst.C.E.—Students' meeting. Friday, February 24th, 7-30 p.m. Paper to be read on "The Erection of the Superstructure of the Forth Bridge," by Mr. Arthur J. Knowles, B.A., Stud.Inst.C.E.

Liverpool Engineering Society.—Wednesday, 22nd February, 8 p.m. Ordinary meeting. Paper to be read on "Flood Gates and Weirs on the River Weaver," by Mr. J. A. Saner.

Society of Telegraph Engineers and Electricians.—Thursday, 23rd February, 8 p.m. Paper to be read on "The Present State of Fire Telegraphy," by R. von Fischer Treuenfeld.

Royal United Service Institution.—Friday, 24th February, 3 p.m. Paper to be read on "How to secure our coast line generally against sudden attack with the means of defence at present available, or with such means as might be made available at a few weeks' notice," by Colonel Sir Charles Nugent, K.C.B., late R.E.

PRICES CURRENT, 16th February.

Quotations at per ton, unless otherwise specified.

" English Ingots	161	0	0	"	162	0	0

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Quotations for Chili bars have been stronger during the past week; sharp cash parcels at the time of writing closing at £78. Manufactured prices unaltered. There is, however, amongst buyers a better feeling springing up, as they become used to the new range of prices.

Tin is a trifle lower than in our last, but appears to be steadying.

Lead firm, with an upward tendency.

Spelter.—This metal is recovering slowly from the recent fall in prices, and seems likely to reach the figures lately ruling.

HOME INDUSTRIES.

MANCHESTER, 16th February, 1888.

The Cotton Trade.—There is nothing new to report in connection with this trade. The buying of yarns is proceeding at an unsatisfactory rate. As far as possible buyers are keeping aloof, and are thus endeavouring to lower the prices; while spinners, being in many cases under contract, are indisposed to meet the competition. Manufacturers experience great difficulty in obtaining prices which are at all remunerative, and are being daily placed in a more unfavourable position. Profits are being made in both spinning and weaving; but the great increase of manufacturing power, together with the stationary condition of spinning mills, is tending at present to give the spinners better prices, and the manufacturers a materially diminished margin of profit. It is interesting to note the various plans pursued by limited companies with reference to depreciation. Thus two mills with 85,920 and 84,024 spindles respectively have set down for depreciation during the past three months £1,000 and £1,142. Again, two other mills, with 120,219 and 118,540 spindles, depreciate respectively for the same time £1,350 and £1,064. These differences are very marked, but may be accounted for by the difference in the age of the concerns and the state of the capital account. The gross profits per spindle of the four are respectively 8·25d., 8·05d., 8·06d., and 6·55d. In the latter two cases it is the more heavily depreciated mill which shows the best results. The gross profits per spindle range from 15·2d. to 4·58d. for the three months, a difference which is somewhat striking.

The Late Jubilee Exhibition.—A meeting of the Council of Guarantors was held yesterday at the Town Hall, when the Chairman of the Executive Committee submitted an abstract of accounts, prepared by Mr. A. A. Gillies, the secretary, and audited by Messrs. Broome, Murray, & Co. Appended to the abstract was an approximate balance sheet made up to the 21st January, which went to show that the estimated surplus on that date amounted to £43,239. 6s. 1d.

The Ship Canal.—The works in connection with this undertaking are being very rapidly carried out, and a large amount of plant is being put into operation. Speaking at the annual gathering of the Manchester Association of Engineers, Mr. Leader Williams, C.E., said that great progress was being made, mechanical appliances from all parts of the world being in operation which were equal to the labour of ten thousand men. The contractor has several vexatious actions pending against him for alleged damage to the roads in several localities, and the amounts claimed are very large in some cases.

A New Damping Apparatus.—Before subjecting cotton cloth or prints to the action of calender rolls, it is usual to damp it by means of a fine spray thrown upon it. Mr. James Parrott, of Salford, has introduced a new spray producer, consisting of a wooden roller into which are fixed a number of serrated steel plates. The teeth of the plates are long, so that when the roller is revolved at a high speed in a water trough, a very fine and continuous spray is thrown upon the under side of the cloth. The makers state that this contrivance is found to be much superior either to a brush or a spray producer such as ordinarily used, the water being more perfectly distributed, and with less liability of accident or damage.

LONDON, 16th February, 1888.

The Money Market.—A languid activity prevailed in the money market this week on account of the settlement, and the demand for accommodation in this connection was by no means great. With a few exceptions, the rates for loans remained at the same low level which has now prevailed for a considerable time. The Stock Exchange is beginning to recover from the depressing influences of the past fortnight. A tendency showed itself even before the close of the last account to transact business for the new one, and the result has been a distinctly firmer tone. Still the markets are not in a secure or normal condition, the recent scare having rendered them peculiarly sensitive. Home securities are distinctly better, but the American market is inclined to fall. This tendency was fully anticipated, but a marked recovery is looked for in American railways in the course of a few weeks. The shares of the Cape Copper Company have benefited by the move. A disposition is shown to invest in the Indian gold mines upon prospects which appear to be sound. People are discussing what is to be done with the £750,000 which is asked for as the capital of the European and American Machine Made Bottle Company. A considerable slice of the money must have disappeared in advertising, which has been indulged in to an extremely wide extent.

Companies.—Since our last report, the following new companies have been registered: Midas Goldfield Company, Limited (Victoria), with a capital of £180,000; Golden Queen, Limited, with a capital of £180,000, to carry on mining operations in the United States; the Syndicate of South African Prospectors, Limited, with a capital of £25,000; the Tetuan Gold Mines, Limited (South America), with a capital of £200,000; Australasian Gas Association, Limited, with a capital of £250,000; Gard and Co., Limited, with a capital of £10,000, to carry on business as manufacturers of self cleaning chemical plate cloths; Blue Spar and Gabriel's Gully Consolidated Gold Company, Limited (New Zealand), with a capital of £130,000; Ashton Brothers & Co., Limited, with a capital of £250,000, to acquire cotton spinning businesses at Hyde and Newton, Cheshire; Electric Traction Company, Limited, with a capital of £30,000; Eclipse Electric Lighting Syndicate, Limited, with a capital of £20,000; Fourness Regenerative Lamp Company, Limited, with a capital of £50,000; West Argentine Extensions, Limited, with a capital of £50,000, to work mines in the Argentine Republic; the Bratsberg Copper Company, Limited, with a capital of £120,000; the Marsh Light Company, Limited, with a capital of £5,000, to carry on business as gas engineers; Treveddoe Tin Mining Company, Limited, with a capital of £50,000; Oldham Mineral Water and Beer Bottling Company, Limited, with a capital of £3,000; Gamble's Window and Lock Alarm Company, Limited, with a capital of £25,000; and the African Prospecting Syndicate, Limited, with a capital of £6,005.

Board of Trade Returns.—The exports for January amount to £18,583,671, as compared with £17,808,735 in the same month of 1887, an increase of 4·3 per cent. Iron and steel show a marked improvement, the quantity being 5·5 per cent. and the value 16·5 per cent. higher than last year. The exports of copper have increased by over 12 per cent. in quantity, and a very much larger increase is of course shown in the value, viz., 70·5 per cent. Cotton piece goods have fallen off a little, owing to a smaller demand for the Indian market. The value of imports for the month amounts to £34,803,000, as compared with £31,047,422 in January, 1887, an increase of 12·1 per cent. The quantity of wool imported shows an increase of nearly 50 per cent.

Textiles.—The attendance at the first series of public sales of Colonial wool, which opened on the 31st ult., has been satisfactory. The market shows a considerable improvement, and the demand is good. Manilla hemp for present delivery is scarce, and prices have consequently risen. The Russian markets are somewhat firmer.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 5th February, amounted to £1,125,672 on 15,831½ miles, as compared with £1,112,707 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 122¾ miles, or 0·7 per cent., and in the receipts of 1·1 per cent.

Exhibitions.—The seventh annual Sportsman's Exhibition was opened last week at the Agricultural Hall, Islington. As usual, it comprised a large number of exhibits connected with aquatics, cycling, shooting, driving, and fishing; but there was little which was new. The most noticeable novelty was Hannay's patent window for hansom cabs, shown by the Forder Company, Limited, which consists of a single pane of glass, instead of the usual double frame, the lowering of which is so productive of discomfort and damage to hats. The new arrangement can be adjusted either by the driver or the occupant, and when being opened, slides against the roof of the cab; it can also be left partly open for ventilation. Messrs. Parkin & Webb exhibited a ramped wheel tyre, made of mild steel, in which oblique cuts are made on both sides of the tyre, so as to prevent skidding on tramways, the object being the same as in Fox's corrugated tyre, described in *Industries*, Vol. III., page 186. A new reservoir fire engine, the "Merton," was shown by Messrs. J. H. Heathman & Co. It is portable, and contains 36 gallons of water.

Technical Education.—In our issue of the 23rd December last we reported a conference on technical education, which was held at the Royal Victoria Hall. The discussion was adjourned at the time, and was resumed yesterday evening at the same hall, when Sir Douglas Galton occupied the chair. Last autumn two conferences were also held at the Finsbury Technical College, on the same subject. These were followed up by one last month in connection with the cabinet making trade, and last night by one for bricklayers, when a paper was read on "The Technical Education of Bricklayers and Brickcutters," by Mr. H. W. Richards. On Saturday there will be a conference of carpenters and joiners.

GLASGOW, 16th February, 1888.

The Copper Syndicate.—The Tharsis Sulphur and Copper Company have announced that they have entered into an arrangement with the Société des Metaux, Paris, for the sale of its output of copper for three years. The Cape Copper and the Rio Tinto companies having already come to an agreement with the syndicate, and the Mason and Barry Company being expected to follow suit, the syndicate may be regarded as having acquired the strength necessary to maintain its position as arbiter of the copper market.

Coal Trade.—Large contracts are reported to have been made by local firms during the past few days. Among these are mentioned 20,000 tons of coal for the Swedish State Railways, 15,000 tons having been placed with Messrs. James Nimmo & Co., and 5000 tons with Mr. Forrester, of Roughrigg Collieries, near Airdrie. Mr. Forrester has also a contract of 40,000 tons for the Danish State Railways.

Engineering.—Messrs. James Donald & Son, engineers, Johnstone, near Paisley, have received from Messrs. Archibald Orr, Ewing, & Co., of Levenbank Print Works, Alexandria, instructions to make machinery for the new process of rapid turkey-red dyeing which the latter firm are about to adopt.

New Railway.—An agreement is announced to have been entered into by the Caledonian and North British Railway Companies and the Kilsyth and Bonnybridge Railway for the joint working of this new local line. The line is expected to be open early in spring.

New College for Glasgow.—The text has been published of a Bill which has been introduced into Parliament by one of the members of the city (Mr. J. G. A. Baird). The object of the Bill is the establishment in the east end of the city of a college of the University of Glasgow. The governing board of the college is to be composed of persons chosen by various public bodies, and of a number of persons *ex officio* — *e. g.*, the Chancellor of the University, the Lord Provost of the City, and the Chairman of the Glasgow School Board. There is thus an important difference between the constitution of this body and that of the governing bodies of the chartered universities, there being none of the teaching staff upon the governing body of the college. Powers are taken to found professorships and lectureships in any subject or in any branch of learning the governors may direct. But the intention is understood to be in the meantime simply to consolidate the medical school as at present carried on in the Royal Infirmary, to make it the medical faculty of the college, and to proceed thereafter with the organisation of the faculties of arts, law, &c.

Fiscal Reform.—A meeting was held in Glasgow last week, to receive reports from a number of sub-committees appointed at previous meetings to inquire into the incidence of foreign tariffs upon various industries. Reports were given upon the "Iron and Steel Industries," by Mr. James Neilson, of the Summerlee Iron Works, and upon the "Scotch Fishing Industries," by Sir James Maitland, Bart. Both papers gave interesting statistics of the conditions of the industries concerned.

International Exhibition.—The buildings are so well forward that there is no doubt that they will be ready in time for the reception of exhibits. At a meeting of the Executive Council at the end of last week, it was announced that the offer of Messrs. A. & J. Stewart for steam piping, and that of Messrs. Ross & Duncan for electric light shafting, had been accepted; also that Messrs. Wordie & Co. had been appointed official carriers to the Exhibition. Arrangements have also been made for the exhibition of a working dairy.

(From our own Correspondents.)

LIVERPOOL, 15th February, 1888.

The Mersey Railway Company.—This great public work, which, since its opening, has been of such advantage to the inhabitants of Lancashire and Cheshire, is likely to prove financially disastrous to the original shareholders. The affairs are now in the hands of an official receiver, and as a preparatory statement to the official report ordered by the High Court of Justice, Mr. Samuel Lack Mason, one of the receivers and managers, has addressed to the directors an elaborate report of the finances of the company. Stating the facts briefly, the company has, up to the present time, spent £1,000,000 of ordinary capital, £500,000 of preference capital, and £576,600 of debenture stock, and is still saddled with a floating debt of £226,000. The works are not yet completed; the estimated cost of completing the Boldstreet Station is £183,775, and for constructing the Rock Ferry Line and Station £110,500. These amounts, added to the floating debt, make a total of £520,556, to provide which the financial proposals contained in the Bill deposited in Parliament have been formulated. Mr. Mason points out that there are two alternatives—either to employ the present resources of the company, which could only be adopted by issuing the stock at a ruinous discount, or to rely upon the proposed new powers, when first debenture stock could be issued with priority over all others, redeemable in five years, the latter course being more preferable.

Engineering and Shipbuilding.—Several important orders have been booked since the New Year, and many of the yards have now a more active appearance. Messrs. Laird Brothers, Birkenhead, are converting one of the London and North-Western Railway Company's passenger steamers on the Holyhead and Dublin route from a paddle steamer into a twin screw steamer, and expect to have it completed within four months. They are also constructing a war steamer for the Colonial Government, specially intended for navigating the rivers of the West Coast of Africa.

SHEFFIELD, 15th February, 1888.

The Condition of Local Trade.—The smallpox epidemic at Sheffield has undoubtedly injured local trade, but the injury is confined chiefly to shopkeepers and holders of licensed premises. The Corporation and other public bodies, acting in concert with Dr. Barry, the medical officer sent down by the Local Government Board, are doing everything in their power to check the epidemic, and there is a very sanguine hope that the town will soon be entirely freed from smallpox. It is suggested that for the benefit of business men visiting the town there should be some official notification of the districts in which the disease is most prevalent.

Iron and Steel.—So far as these industries are concerned, trade has not been so brisk for some years past. Orders are coming in freely for nearly all descriptions of heavy material, and at many of the large works there is great activity, though prices for the last day or two have been fluctuating a little. Hematite has ranged from 51s. 6d. to 52s. 6d. and 54s. 6d. per ton; forge and foundry have changed hands at from 51s. 6d. to 53s. 6d.; and Lincolnshire pigs

Digitized by Google

have been quoted at rapidly changing prices from 34s. 6d. to 37s. 6d. per ton. At the Sheepbridge Iron Works, near Sheffield, where a good deal of Derbyshire pig is turned out, there is a decided improvement in trade, with a prospect of a busy time through the spring. For merchant bars as much as five guineas, and for sheets up to six guineas per ton have been realised. Steel rails, that have been sold at a much too cheap rate for years, are now realising more profitable prices, and for all classes of railway material—rails, tyres, axles, and springs—there is a good demand. Ship plates and heavy machinery are ordered more readily, and one or two of the best known engineering firms in Sheffield are doing excellently on home and foreign orders. Indeed, nearly all the heavy branches are in a more flourishing condition, and the bulk of work turned out is exceptionally large.

Mitis Castings.—These castings appear to have been extensively adopted by firms who formerly made use of malleable iron and brass castings, or manipulated iron and steel forgings. Mitis castings can be welded and hardened, and as they require no annealing they can be supplied in a few days. Messrs. Hansell & Co. and Messrs. Seebohm and Dieckstall, of Sheffield, were the pioneers in the manufacture of these castings in Great Britain, having obtained licenses from the Castings Improvement Syndicate, who previously granted licenses to several foreign firms in France, Germany, and Sweden. The Eureka Cast Steel Company have just closed a contract with the United States Mitis Company for the right to manufacture castings by the Mitis processes for certain districts, in conjunction with the Midvale Steel Company, who are also licensees. Up to the present time the Sheffield plant has been restricted to the production of small castings, but we understand that considerable extensions are in contemplation.

NORTH STAFFORDSHIRE, 15th February, 1888.

The Iron Trade.—Specifications are coming in but slowly, and most of the works are running short time. The small advance in price secured in January has fallen off, and the old unremunerative rates prevail. Deliveries of pig iron continue on contract, but consumers are for the most part fully bought for the current quarter. As some makers are getting anxious as to the future, and forcing iron on the market, it is likely that prices will further recede.

The Coal Trade.—The recent cold weather gave an impetus to the house coal collieries, which are now working full time, and are still unable to fully supply their customers' requirements. The demand for forge and manufacturing coal is fairly good, at a basis of about 7s. at the pit. The operation of the Mines Bill is a source of great worry to managers, and expense to colliery owners.

The Pottery Trade.—The condition of this industry has shown some signs of improvement since Christmas, and the outlook is now hopeful. Manufacturers, however, still complain bitterly of prices, which are low and unremunerative. The operation of the associations lately called into existence with a view to advance prices, is being watched with curious interest, and should it prove successful in checking the keen competition for orders which is now rife, a great boon will have been conferred on the district.

Engineering.—In every branch trade is dull and prices low. Local founders find it difficult to get orders and to make both ends meet. At Crewe the workmen are still on short time, and there seems little prospect of any change for the present.

BARROW-IN-FURNESS, 15th February, 1888.

Great Shipbuilding Scheme.—The scheme previously alluded to in these columns, by which a new company proposed to take over the business and works of the Barrow Shipbuilding Company, has been realised, with Lord Hartington as its chairman, Lord Brassey as its vice-chairman, and Mr. Nordenfelt as one of its directors. It is significant of the operations of the new company that it has acquired some of Mr. Nordenfelt's patents, particularly in ship construction, and it is proposed to build Nordenfelt torpedo boats and other classes of modern war ships, for which purpose all the features of a naval dockyard are to be established. The Barrow Steel Company are laying down new plant for the production on a large scale of Siemens-Martin steel in plates, angles, and other shipbuilding material. Barrow will thus be doubly benefited by this new development, and a large amount of work will be furnished for its docks and harbour. The district abounds in iron ore, from which Bessemer and Siemens-Martin steel of high quality is readily made.

Iron and Steel.—There is a quieter tone in the hematite pig iron trade this week, consequent on speculative operations, and business in hematite warrants has been done as low as 39s. per ton. Makers, however, do not recognise this figure as representing the position of the market, and are quoting 43s. per ton net f.o.b. for Bessemer iron in mixed numbers, with 42s. 3d. for forge and foundry iron No. 3, at which prices some well known brands have been sold. Steel rails are in fair request at the steady price of £4 per ton for heavy sections. A good business is doing in ships' plates, angles, &c., the former at £7. 2s., and the latter at £6. 7s. 6d. per ton net f.o.b. Engineers are busily employed, and orders are offering which are likely to be accepted and bring about renewed activity both in this and the boiler making industry. Iron ore is not so active as of late, and prices are down 6d. per ton, ordinary qualities being quoted at from 9s. to 12s. per ton net at mines. The shipping trade is well employed for the time of the year.

MIDDLESBROUGH, 15th February, 1888.

Pig Iron.—The pig iron market is quite a dissappointment this month. The fall in prices is most marked, and shows a decrease from 32s. in January to 31s. 6d. in February for No. 3 G.M.B., prompt delivery. This is not iron in makers' hands, however. They maintain their price on the basis of 32s. 6d. to 35s. per ton for prompt f.o.b. deliveries of No. 3. Forge iron even in merchants' hands maintains its price at 31s. per ton, as it is in good request on account of the improvement in the finished iron trade.

Shipments of Pig Iron.—The shipments of pig iron from the port of Middlesbrough up to the 13th inst. are about 6000 tons more than in the last month, and about 6300 tons more than in the corresponding month last year. The improvement is not restricted to any particular direction, but is general. The falling off of shipments to America amounts to between three and four thousand tons.

Iron and Steel.—In the finished iron trade the improvement is still maintained. The works have plenty of orders to keep them going for the next two months or more, so that there is not the anxiety to press for further orders. Prices are unchanged; common bars are from £5, plates from £5, ship angles £4. 15s. per ton on trucks at works. In finished steel there is not the same activity, and prices are hardly so strong. Rails, from £4, according to section; ship plates, £7; ship angles, £6. 10s. per ton in trucks at works, less the usual discount. The North-Eastern Steel Works are again fully employed, the difficulty with the men having been settled some time ago. The Eston Steel Works also are as busy as they can be. The public have been rather startled to hear that the general manager, Mr. Richards, has resigned and accepted the managership at Low Moor. This change has no connection with the Lloyd's inspector difficulty.

Shipbuilding.—The strike at the Cleveland Dockyard has been settled by a friendly arrangement between the masters and the men's representatives. There are favourable accounts from all the yards in the district.

Salt.—The boring at Seaton Carew, which was reported as unsuccessful so far as the salt bed was concerned, is said to have struck a brine spring saturated with 20 per cent. of salt, so that it is not so bad as was represented. They are still boring further down than the 1200ft., in hopes of striking a coal bed.

SUNDERLAND, 15th February, 1888.

Shipbuilding.—Local shipbuilders continue to obtain a fair share of the orders in the market. Messrs. J. L. Thompson & Sons, North Sands, have added another to their list, a steel screw steamer of about 2700 tons dead weight. Messrs. Wm. Pickersgill & Sons, Southwick, have booked an order for an awning deck screw steamer, 220ft. in length, for China river trading. Ship repairing continues to be very brisk, the salved steamers, "Pinnas" of Hamburg, and "Saltburn" of Sunderland, being the most recent important additions to this class of work.

Marine Engineering.—All the establishments are now actively employed. At Mr. John Dickinson's Palmer Hill Works there are eighteen sets of engines in hand, one of which is a quadruple expansion engine, 16in., 22½in., 38in., and 52in. cylinders, 30in. stroke, for the old steamer "James Drake." In this instance the old columns, shafting, &c., will remain, the principal addition being the four new cylinders. Messrs. William Doxford & Sons have five triple expansion engines in the course of construction for vessels which are being built in their shipbuilding yard. The extensive additions and alterations at Messrs. Allan & Co.'s (late Carr & Co.'s), Limited, works, continue to progress rapidly, and arrangements have been completed with the River Wear Commissioners and the Corporation for the erection of a deep water quay at the river front of the works.

The Coal and Shipping Trade.—The coal shipments during the last week reached 75,277 tons, of which 14,433 tons were exported and the remainder shipped coastwise. In the previous week, the shipment was 90,721 tons, 5073 tons in excess of the corresponding week of last pear. The general export trade also continues to be favourable, last week 2700 tons of patent fuel, 1160 tons of coke, 17,000 dozens of bottles, 122 tons of cement, and 50 tons of fire clay being shipped.

Rope Manufacturers.—The manufacturers of iron and steel ropes are now well employed, owing to the recent influx of shipbuilding contracts; but the competition is so severe that only a small margin is left for profit.

Chemical Works.—The Wear Patent Fuel Company, South Docks, are sharing in the improved state of trade, both in their fuel manufacture from the residues of tar distillation, as well as in the costly products of aniline, alizarine, &c. In all their departments night work is being carried on.

NEWCASTLE, 15th February, 1888.

Rope Works.—Within the past three or four weeks rope manufacturers have added considerably to the number of orders on their books, most of the new contracts secured having come from northern shipbuilding firms, and consisting mainly of wire rope for rigging, &c. The requirements of colliery owners have also helped to increase the amount of prospective work, and on the whole, the industry may be described as in an exceptionally healthy state.

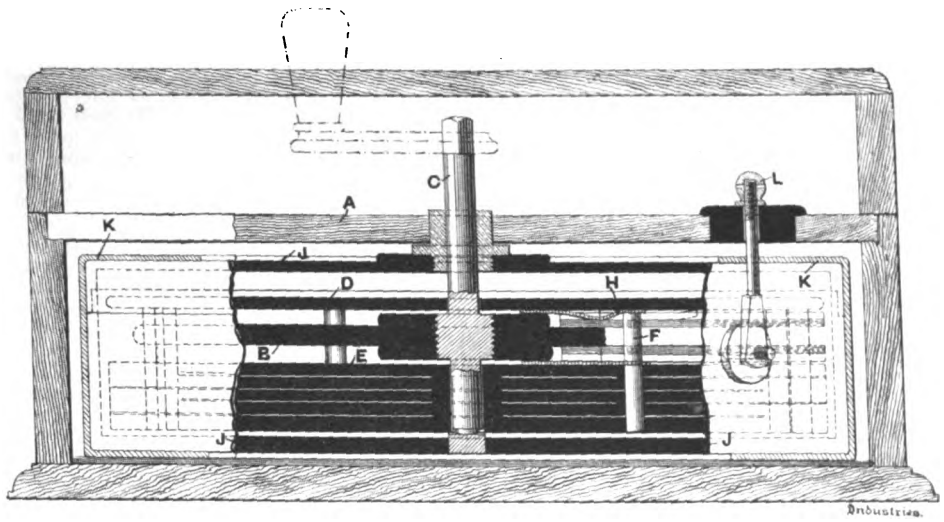
Glass Works.—In the pressed glass trade business continues good; but the brisk season in the lamp chimney trade is drawing to a close, and the pressure of work is already sensibly lessened in establishments which make that branch their specialty. The Gateshead Stained Glass Company, who have already a good many forward orders booked, are now in negotiation for a contract of more than ordinary importance. There is still a large demand for "polished plate," and the works in which that commodity is produced are as busy as could be wished.

Carriage Works.—At the old established carriage and harness manufactory of Messrs. Atkinson & Philipson, Pilgrim-street, Newcastle, the state of business is, for the time of the year, exceptionally good. In the course of a few weeks, however, a large increase of work is anticipated, and the extensive resources of the firm will then, it is expected, be very fully utilised. That the demand for the productions of this firm is not confined to a limited area, is seen by the fact that they have recently shipped specially ordered carriages and harness to Bathurst (West Coast of Africa), Sierra Leone, Lucknow, and Bombay. They have other foreign orders now on hand, in addition to those that are being executed for customers in different parts of the United Kingdom.

Wire Works.—Wire working establishments are at this moment somewhat slack, excepting in the case of Messrs. W. Mountain & Sons, New Bridge-street, who, being principally manufacturers of window blinds and appliances used in paper manufactories, are experiencing a steady demand for their specialties. Messrs. Foggin & Co., High Bridge, cater chiefly for the requirements of collieries and brick making works, and the demand from these sources is just now greatly reduced. In a short time, however, the demand for articles required in gardening and agricultural pursuits will give a considerable stimulus to the industry.

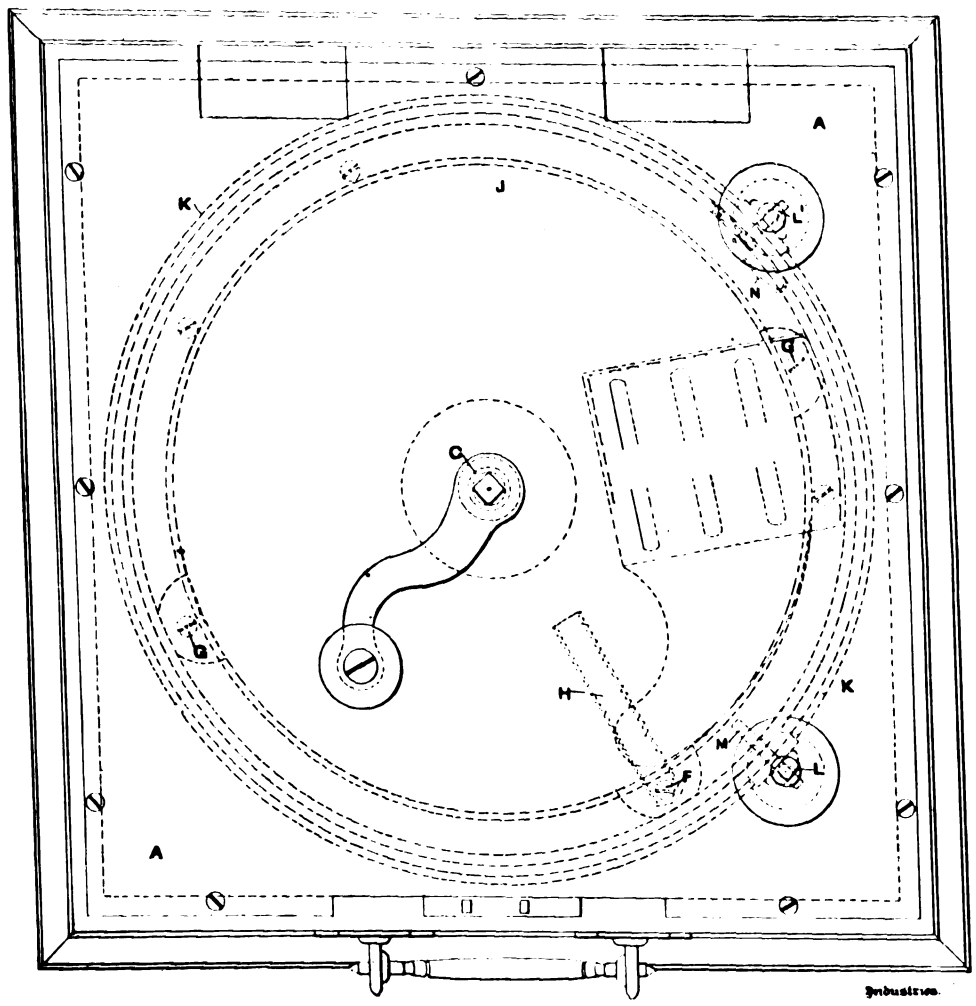
Leather Works.—The state of business in the leather and india-rubber trades has undergone little change during the past few weeks, but the outlook for the latter branch especially is cheering. The well known firm of George Angus & Co., leather factors and manufacturers, has been registered as a limited company.

Ship and Engine Forgings.—These establishments on the Wear, which are specially adapted to ship and engine forgings, are exceptionally busy just now, and so great is the pressure of work that in some instances it has been found necessary to make extensions and put down new plant. The marked increase of business at those establishments is, of course, to be attributed to the improvement in the ship building and marine engine industries; and according to the present outlook in the latter trades a still greater accumulation of orders in the hands of forge proprietors is likely to take place ere long. The most recently constructed establishment of this description in the district, viz., the King's Forge, Pallion, is at present inoperative; but as it is offered for sale, it is not likely to remain long in this condition, and will no doubt soon be helping to supply the pressing requirements of engine builders and shipbuilders.



DUNDEE, 15th February, 1888.

Flax and Jute Trades.—The textile idustries of Dundee and district have not undergone any material change during the last fortnight. The linen branches have shown more activity than the jute trade. In flax the demand has been chiefly confined to spot goods at about previous prices. For shipment the tendency is in favour of buyers. Flax yarns are selling at comparatively low rates. Spinners are unwilling to give way in price, but they find it difficult to effect sales. Moderate business is reported in linen goods at late prices. Throughout Fife manufacturers are well employed, and forward orders are understood to be fairly plentiful. Telegrams from Calcutta report a dull market for jute, without change in rates. In jute yarns a moderate business is passing, and spinners are firm in their demands. Hessians meet with only a moderate inquiry, and there is not more business passing than suffices to take off present production Sacking continues in fair request, and the demand for tarpaulin and bagging is fairly active. The jute spinners and manufacturers have resolved to stop the spinning and weaving departments for a period of three months, commencing the first Saturday of March.



Erection of New Works.—A new carpet weaving factory was opened here last week. The machinery is driven from tunnel shafting, power being transmitted to the wing shafts by noiseless helical toothed bevel wheels, One advantage of this arrangement is that the light from the roof is not obscured by overhead gear. The driving moreover is very steady. The factory is heated by wrought iron steam pipes, which are led round the room on brackets attached to the supporting pillars. At night the factory will be entirely lighted by means of electricity. The installation consists of 423 lamps of 16 c.p., and there are also some lamps of 32 and 50 c.p. Narrow looms are lighted from one lamp, but the wider looms require two. The lamps used are of the Edison-Swan incandescent type. As a precaution against accident the factory is fitted up with gas lamps, which can be lit without interruption of the work.

AN IMPROVED MINE EXPLODER.

SECTIONAL ELEVATION.

GENERAL PLAN.

AN IMPROVED MINE EXPLODER.

THE above illustrations represent in section and plan an improved form of mine exploder, manufactured by Messrs. David Moseley & Sons, of Manchester. The apparatus is enclosed in a square wooden box, and is further protected within the box by the cover A. It consists of the rotating vulcanite disc B, which is firmly fixed to the vertical spindle C, upon the upper end of which a square is formed for the handle to fit upon. Above the rotating disc is a fixed disc D, and below it a thick fixed disc E, within which is the condenser indicated by the thin white lines. The sheets of tin foil forming the condenser are placed in the disc before it is vulcanised, and the sheets are connected alternately to the posts F and G, F being connected to the collectors H. There are two rubbers, kept in contact with each of the surfaces of the rotating disc, and having the form indicated in dotted lines in the plan. These rubbers are of special construction, and are charged with an amalgam, the nature of which appears to have a controlling effect in securing a very high efficiency for the apparatus. The rotating and fixed discs are enclosed within a circular vulcanite box J, which is as nearly air tight as possible; but in order to secure the total exclusion of atmospheric moisture, a deep U shaped soft india-rubber ring K is slipped over the edge of the box. The terminals L L^1 are connected by metallic posts—L to the stop M, and L^1 to the flattened spring N. If the disc B is rotated, the thick disc J and the thin disc D are carried with it until their motion is arrested by the contact of the post G with the stop M. The motion of the disc is continued for about twenty-five revolutions, when the direction of rotation is reversed through about a quarter revolution. This brings the post F in contact with the terminal post M, and the post G in contact with the spring N, and consequently puts the condenser, which is now fully charged, into the external circuit. The apparatus produces a full thick spark through a 2in. air space, and is capable of simultaneously exploding 1000 submarine fuses in series. Its weight is precisely one-third (18lb.) that of the ordinary magneto exploder, and it occupies a somewhat smaller cubical space. The positions of the posts F and G are those occupied by them just after the commencement of charging and just before discharge.

THE PHYSICAL SOCIETY.

THE annual general meeting of this Society was held on the 11th inst., and after the reading of the report for the past session, and of obituary notices, by Dr. Gladstone, vice-president, the officers and council were elected for the coming session. Professor Reinold, F.R.S., was elected president, in the place of the late Professor Balfour Stewart, and Professor Perry takes Professor Reinold's place as one of the secretaries of the Society. The first paper read was by Mr. T. Pelham Dale, "On the Limit of Refraction in Relation to Temperature and Chemical Composition." The author showed, many years ago, that Cauchy's generally accepted formula expressing the relation between the wave length of a ray of light and its velocity of propagation in an isotropic medium does not give even approximately correct results, except within very narrow limits. In the present paper, the author obtains some formulæ which are found to agree more nearly with the results of experiment; but there is a fairly uniform deviation from theory in the relation between wave length and dispersion, and the uniformity is specially marked in the case of chemical compounds of similar molecular structure. Some anomalies are found to exist in the dispersion in flint glass and some kinds of sulphide of carbon, and still more markedly in the case of selenium. The author assigns, as the probable cause of the deviations from theory, the loss of energy arising from the transformation of light into heat when passing through the medium; and he is of opinion that, in the case of selenium, this is confirmed by its other peculiarities. After some remarks by Dr. Gladstone and others, Mr. Bosanquet read a note on the use of the term "resistance" in the description of physical phenomena. The note was suggested by an objection raised by Dr. Hopkinson to the use of the term "magnetic resistance," on the ground that the quantity so designated is not a constant for a given circuit. The author considers that any physical change may be considered as made up of a cause and an effect. If there is an opposition to the change which is greater, the greater the measure of the cause and the less the measure of the effect, he calls it resistance. Ohm's law is one of the most familiar examples, and in this case we have resistance=cause/effect. As another example, he considers the compression of a substance into a smaller volume. Here the pressure is the cause and the corresponding compression is the effect, and the resistance is a function of the effect, as is the case with magnetic resistance, which is a function of the magnetic induction. Objections have been raised against the term magnetic resistance on the ground that it is not of the same dimensions as its electrical analogue. But the objection would be equally applicable to the terms magnetic potential and magneto-motive-force, and, in fact, it is merely an objection to an analogy; that it is not an identity—which, of course, is not asserted. The author defines resistance at a point of a curve, giving its variation as the quotient of the small change in the cause by the corresponding small change in the effect, subject to the sum total of the conditions undergoing only a small change in the interval; in mathematical languages it is expressed by differential of cause / differential of effect. As an example, he gave Lamont's formula for a magnet, and defended his definition of magnetic resistance as the quotient of magneto-motive-force by magnetic induction, against M. Hospitalier's recent criticism that the denominator should be the total magnetic flux instead of the magnetic induction (or flux per unit of area), on the ground that his own definition, by making the magnetic resistance a linear quantity, greatly simplifies practical calculations. Professor S. P. Thompson mentioned that Rankine had used the term thermal resistance as the reciprocal of thermal conductivity, and he suggested that we might, by analogy, call it the quotient of thermo-motive-force by the thermal flux. He also instanced the characteristic curve of a series dynamo, where if ampères be taken as abscissæ and volts as ordinates, gives the resistance of the circuit as the tangent of the slope at the corresponding point of the curve. He thought it would be very useful to draw characteristic curves to express mechanical conditions. For example, instead of constant speed, we might draw a curve for constant driving moment; or, again, for a shunt wound motor, we might take speeds as abscissæ and the corresponding torque on the axle as ordinate, and we should have resistance to driving equal to torque/speed.

Professor Ayrton considered that the expression resistance=cause/effect should be confined to cases where this quotient was fairly constant, as was the case for magnetic resistance, except for very small magnetising force and near saturation.

Professor Foster mentioned that, in teaching mechanics, he found it useful to define inertia as the measure of resistance to change of velocity (inertia=force / acceleration), and moment of inertia as the measure of resistance to change of angular velocity.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Industries:

FRIDAY, 17TH FEBRUARY, 1888.

PROPOSED LEGISLATION FOR STEAM BOILERS.

THE correspondence which we have published in our columns during the last few weeks, and that which appears in our present issue, together with the action recently taken by the Oldham Chamber of Commerce, are sufficient to show that at least some of the steam using public are beginning to appreciate the importance of the proposed boiler legislation and its probable effect on our industrial progress. We need hardly state that any subject which materially affects the manufacturing interests of this country comes within our special province to discuss, and we therefore intend to devote some space to a consideration of the boiler legislation brought forward during last session, and which, together with a Bill just proposed by Mr. Provand, may be introduced during the present year. While we, of course, are not bound by any opinions expressed in our correspondence columns, we believe that our readers will agree with us in thinking that the facts put forward in opposition to the proposed legislation by our able correspondents "Economiser" and "Boiler," deserve careful consideration, not only from steam users generally, but from the Board of Trade officials, upon whom some rather severe comments are made. We presume, however, that these gentlemen will at the proper time and place be able to look after themselves, and give what they may consider sufficient reasons for the opinions they have officially expressed. We may therefore proceed by explaining that two measures dealing with the supervision and inspection of steam boilers were brought before Parliament last year. The first was the Bill backed by Mr. Burt, Mr. Crawford, Mr. Abraham, Mr. Fenwick, Mr. Pickard, and Mr. Dyke-Acland, and was entitled "The Steam Engines and Boilers Bill," and the second was the Bill introduced on behalf of the Board of Trade, by Lord Stanley of Preston, entitled "The Boiler Registry and Inspection Bill." The object of the first measure was to compel all boiler attendants to pass an examination before, and to receive a certificate from, the Board of Trade. The object of the second measure, briefly stated, was to compel all owners of boilers to register their boilers in a registry to be kept by the Board of Trade, and to have these boilers periodically inspected under the supervision of the Board of Trade. The view of the promoters of the first Bill was that many, if not most, of the boiler explosions which occur, are due to incapable attendance, and that of the promoters of the second was that the number of explosions might be minimised by rendering all stationary boilers liable to compulsory inspection, and thereby dispensing with inquiry as to the competency of attendants. The first Bill was a revival of a similar proposed measure introduced by Mr. Broadhurst a short time before, and rejected on the second reading. An opportunity was not found during last session for the discussion of the new Bill, and there now seems only a small probability of its being again brought forward. The second Bill was read a second time in the House of Lords on the 15th of last August, almost without debate, on the understanding that a Commission on the subject would be moved for early in the present session. It is supposed that this Commission will be largely composed of boiler experts, so that the result of their labours may be the production of a Bill as fitted for promoting public safety as such a measure can well be. Notwithstanding the other Bills proposed, it is likely, unless the recent Ministerial changes interfere, that the discussion on the question of boiler legislation will concentrate itself upon the Bill to be brought forward during the present session by the Board of Trade, and upon the labours of the Commission whose collective wisdom is to be invoked to construct the provisions of a suitable measure.

Some of those interested in the subject would appear to take it for granted that legislation should be carried out whether there is need for it or not, and seem to conceive that the best plan is by timely legislation to anticipate the probability of having to pass a Bill in a hurry in order to satisfy public clamour caused by some serious explosion. For this point of view there is something to be said; but it cannot be held as affording alone sufficient reason for legislation. Two main questions emerge at the outset in seriously considering the subject, viz., what do we really require? and is further legislation the best means of obtaining it? Granted that what we want is public safety, and that the only means of safeguarding the public from the explosion of steam boilers is to have such boilers properly constructed, properly managed, and satisfactorily inspected, it would still be necessary for additional legislation advocates to show that further additions to the statute book of the nature of the proposed Bill will secure these objects. In 1882, a measure was passed called the Boiler Explosions Act, which empowered the Board of Trade to do certain things in the event of an explosion to any boiler coming under that Act. For example, Section VI., sub-section 4, enables the Board of Trade to form a court of investigation which shall have "all the powers of a court of summary jurisdiction when acting as a court in the exercise of its ordinary jurisdiction;" and in sub-section 5 it is enacted that "the court making a formal investigation with respect to any boiler explosion shall make a full and clear report to the Board of Trade stating the causes of the explosion and all the circumstances attending the same, with the evidence, adding thereto any observations thereon, or on the evidence, or on any matters arising out of the investigation, which they think right to make, and the Board of Trade shall cause every such report to be made public *in such manner as it thinks fit.*" Again, in Section VII., we find that "the court may order the costs and expenses of a preliminary inquiry or formal investigation, or any part thereof, including therein the remuneration of persons holding such inquiry or investigation, *to be paid by any person summoned before it*, or by the Board of Trade." It is clear, therefore, from the portions of this statute which we have just quoted, and especially from the words which we have italicised, that the resources of the statute book, as regards steam boilers, are not yet exhausted, for some parts of the Act of 1882 have never yet been put into force.

Having regard to the reduction made in the number of serious boiler explosions since 1882—we use the word serious here advisedly, having in view the wide definition of "explosion" adopted by the Board of Trade—it would be perfectly reasonable to take a stand upon this Act, and specially upon the unused portions of it, and demand that the Board of Trade officials, instead of seeking enlarged powers, should exercise more efficiently the powers they already

Digitized by Google

possess. The common answer to such an argument would be that during the currency of the Act a number of prosecutions have been undertaken against the owners of exploded boilers, while a conviction was only obtained in a solitary case, juries being most unwilling to convict unless a guilty knowledge of the condition of the boiler was absolutely brought home to the person charged. Thus it is held that the Boiler Explosions Act is in that direction practically inefficient, and that more stringent provisions are necessary to secure the public from the danger incurred by the presence of the many steam boilers in use in the manufacturing quarters of our large towns. Yet the failure to carry out the provisions of one Act of Parliament does not form a very substantial reason on which to demand another Act. Besides, past experience of the policy of the Board of Trade, no matter by what political party the Board may for the time be controlled, would lead steam users to expect a perpetual grasping for increased powers, rather than efficient use of the powers it may possess. We do not desire to take up a position unfriendly to the Board of Trade; but in considering this question the public will have a right to demand full information as to how the existing powers of the Board of Trade are exercised, before giving over to it the very extensive additional powers which are proposed in Lord Stanley's Bill. We have on former occasions discussed the extension of the functions of the State, which is at present so marked a feature of our legislation, and need not now do more than point out that the Boiler Registry and Inspection Bill is one of those measures whose intention is avowedly to strengthen and extend the control of the State, through the arm of one of its administrative departments. It therefore demands the most careful scrutiny, not only that the interests of individuals may not be unduly sacrificed, but also that the interests of the public—by no means to be confounded with the assumed interests of the State—may be adequately conserved.

The leading provisions of the Bill, as introduced into the House of Lords by Lord Stanley, are as follow: (1) Existing boilers must be registered. (2) All new boilers must be registered before they leave the makers' premises. (3) Every boiler thus registered must be inspected within twelve months of the passing of the Act. (4) A consultative committee will be appointed to act with the President of the Board of Trade. (5) Any inspecting company or society whose rules are approved by the Board of Trade may appoint inspectors. (6) The Board of Trade may appoint inspectors in any district where provision for inspection is not made by private companies. (7.) Every application for the inspection of a boiler must be made according to certain regulations, and is to be subject to a prescribed fee. After an inspection by the Board of Trade or private company a certificate is to be issued declaring that, subject to the statement as to pressure, the boiler is fit for work. Provision is made for appeal to the Board of Trade, and for the initiation of an inspection by the Board of Trade should it so determine. The Board reserves extensive powers. It may alter the mode of inspection, the proceedings of inspectors under the Act, the forms, fees, allowances, and, finally, any matter authorised by the Act to be prescribed. (8) All rules made under the Act must be submitted to Parliament within a certain period. (9) Boiler insurance societies must pay to the Board of Trade 5 per cent. of the fees received by them under the Act. (10) Offences against the Act are punishable by a fine of £20. (11) All boilers fall under the provisions of the Act, except those in ships classed at Lloyd's, those under the Merchant Shipping Act, those in Her Majesty's use, and all boilers belonging to railway companies, or for domestic use. Having explained the leading provisions, we intend to defer our further comments on this Bill for another occasion; but, in the meantime, we would strongly recommend steam boiler owners to study its various clauses, and decide for themselves how far the proposed legislation will affect their industrial interests, and to what extent it may be objectionable or unnecessary.

MR. GOSCHEN ON EDUCATION.

A Scotch Rectorial address is not a subject which would usually require notice in a technical journal; but the one recently delivered by the Chancellor of the Exchequer at Aberdeen bears so directly on some of the educational questions—general as well as technical—which are now being discussed, that we think it may be interesting to our readers to know some of the opinions of a man like Mr. Goschen, who in his day took a high place as a student, and who is now one of our leading economists and statesmen. Speaking of the prevailing opinion that it was the vastly superior knowledge of our rivals in trade, especially the Germans, that was the most dangerous competing force, and of the inference that we are therefore to bustle into a system of immediate and rapid cram, Mr. Goschen did not hesitate to say that he believed that such a method would be altogether useless. Greater knowledge is good, but there is a higher ideal—greater love of knowledge; and unless a system of education produces this it is largely useless. People may be frightened into working harder, but the results will be disappointing unless they are also made fonder of work. How little it is after all that schools and colleges, even of the highest order, can teach directly. Yet even the humblest of them can do something better. They can develop in their scholars a capacity and inspire an interest, which will cause them to go through life teaching themselves; and Mr. Goschen insisted that this, after all, is the final test of the value of an educational system, whatever its curriculum may be. Is it intelligent? Is it thorough? Above all, is it rousing? Does it excite intellectual interest in those who come under its influence? Does it develop in them the temper which always asks for a reason and struggles to arrive at a principle? He confessed that when he looked at the augmented list of subjects which now figure in our elementary education, he sometimes feared lest it should lull us into the belief that our object is gained if we can only pile up high enough the number of our studies. The question is, whether they are so taught as to expand the mind or merely to fill it? Are the teachers interested? Are they interesting? Do they stimulate as well as inform? He did not wish it to be supposed that he desired to say one word against the wider range and greater variety of modern studies. Variety promotes interest. But the mere multiplication of subjects is not what is essential. What is essential is the intellectual gymnastic which strengthens the mind to grapple with tough problems, and the intellectual interest which leads men to delight in that exercise. The live mind will provide itself with varied knowledge, as the well tilled soil will grow all sorts of crops. But on the half cultivated intelligence the stores of knowledge are lavished in vain, as the best seed is wasted on the unploughed and unharrowed field. To beget a right spirit in education in all its grades is a national work. No mere system can do it; nor does it rest with educationists alone. It is not programmes of study however ample, nor time tables however well constructed, nor examinations however searching, which will make an educated people. We want the steam to drive the machinery as much as the machinery itself. If a strenuous intellectual temper is to become more fashionable in all classes, if the idea of being tired by work is gradually to die out, if all callings are to be endowed with keener interest, it is to public opinion that we must look to effect the change.

The above questions and opinions should be carefully weighed by all who are responsible either for the arrangement or carrying out of education. Too often these are content with drawing out codes and syllabuses, collecting statistics, or preparing the students to meet their requirements, and they never ask whether education in the proper sense of the word is being imparted, or whether the intellectual interest which is essential to success is being generated. Mr. Goschen showed that this interest was as essential in industrial and commercial pursuits as it is in what are usually called the learned professions, and he illustrated this by reference to the controversy or discussion which is now being held regarding commercial education, and especially that part of it relating to the fact that foreigners are ousting Englishmen in our counting houses at home, and in the competition for new trade abroad. German clerks are invading every business house in London, and the reason is said to be their greater knowledge, their command of foreign languages, their acquaintance with all the technicalities of their business, and the excellence of their commercial schools. Conferences have been held to consider the cause of English failure, and remedies have been suggested in plenty to meet an admitted danger. Foreign languages are to be more and more introduced into our educational system. English clerks are to have a special business training; higher commercial schools are to be founded to produce an article capable of competing with the foreign importation. All this is good in its way, but Mr. Goschen pointed out that it may be all labour lost, unless when you have done all this, when you have taught the English clerk five languages, have instructed him in the technicalities of his business, you will not have done enough, unless you have succeeded in making him as fond of his work as his German competitor. There is danger in thinking that it is only knowledge that is lacking—that it is only in width of information that the foreigner is superior. He knows more, no doubt; but that is not the root of the matter. The root of the matter is, that he cares more about his work; that as a rule, he takes an interest in it apart from its results in money, which, for whatever reason, the Englishman has not hitherto learnt sufficiently to take, and this arises in great part from the difference in the methods of German and English educational institutions. The want of thoroughness which we have had to deplore in English middle class and popular education is due in a large measure to the fact that our upper class education had adapted itself to the wants of a section of society which had no need to work. In Germany an opposite social condition produced an exactly opposite result. The great body of students at German public schools and universities, even the most fashionable, are men who have to depend upon their own exertions alone for their future livelihood. The consequence is that hard work, wide knowledge, the thorough ploughing of the mind, are the great objects of the highest education. And the example, which is set on the highest educational plane, has made itself felt down to the lowest. It has made industry, knowledge, and reasoning power, interest and delight in every form of work, national ideals to a degree unparalleled elsewhere. It has carried the scientific spirit into every form of national enterprise, into trade, into industry, even into the operations of war.

Mr. Goschen pointed out very distinctly that changed times require changed methods, both of transacting business and of preparation for it. The merchants of a former generation, who built up the splendid fabric of British commerce, were undoubtedly more conspicuous for unerring instinct and audacity of enterprise than for any intellectual greatness. Their interest in their business was exclusively practical, but none the less they achieved great results, and perhaps persons of their turn of mind and practice do their work with all the more vigour and energy because they have no love for it in itself, and are glad to get rid of it as soon as possible. Their strength lies in their natural shrewdness. They are bored by nothing so much as by a principle. Thousands of people have made fortunes by methods such as these, but circumstances are very much changed from what they were even a few years ago. Our position in the race of civilised nations is no longer what it was. We had a great start in industry and commerce, and by virtue of that start we attained to a station of unprecedented and long unchallenged supremacy. That supremacy is no longer unchallenged. Others are pressing on our heels. We require greater efforts than formerly to hold our own. Mother wit, and boldness in seizing great opportunities—the chief factors in our previous success—are no longer sufficient, if others are to be more strenuous, more painstaking, more widely informed. It is the recognition of this fact which is at the bottom of the great stir in our educational world, of the ever increasing demands made on our elementary schools, of the cry for technical and commercial training, of the new spirit which is manifesting itself in our public schools and universities. If this new movement is wisely guided the pressure of competition, which we feel so bitterly to-day, may be fraught with greater blessings than the easy supremacy of the past. The perusal of Mr. Goschen's speech gave us considerable pleasure, as his opinions agree with those which we have always tried to enforce, and coming from a politician of his standing we trust they will influence education, and also any legislation bearing upon it.

COAL, IRON, AND COGNATE INDUSTRIES.

The Board of Trade Returns for January are, on the whole, satisfactory. In the aggregate there is an increase of £3,755,566 in imports, and of £774,936 in exports, as compared with the same month in 1887. We append our usual tabular statement:—

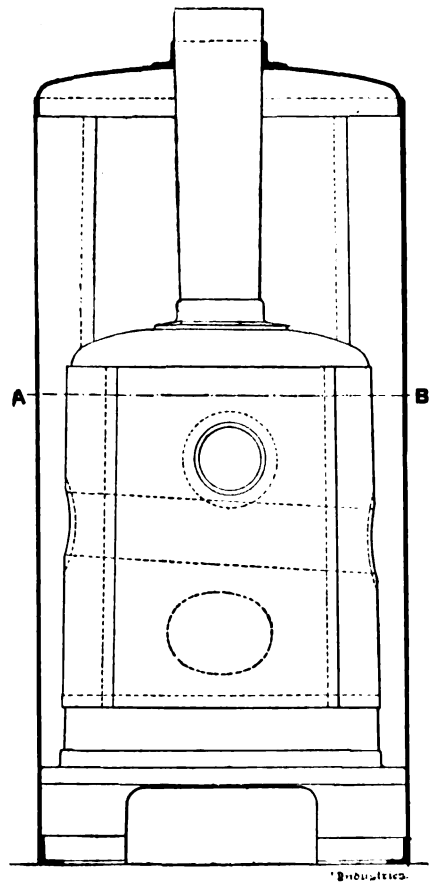
	Month of January. 1888. £		1887. £
Pig and puddled	112,041	.....	149,377
Bar, angle, &c.	132,683	.....	103,539
Railroad	490,489	.....	301,021
Steel, unwrought	108,210	.....	136,284
Coal	752,811	.....	746,338

So far as the iron trade is concerned, it will be noticed that although there is a falling off in our exports of pig iron and puddled bars, it is more than made up by an increase in those of railroad and finished iron. The proposed alteration in the American tariff has not had the effect, anticipated in some quarters, of increasing the imports of iron. There is a diminution of over 9500 tons, as compared with the corresponding month of last year,

Digitized by Google

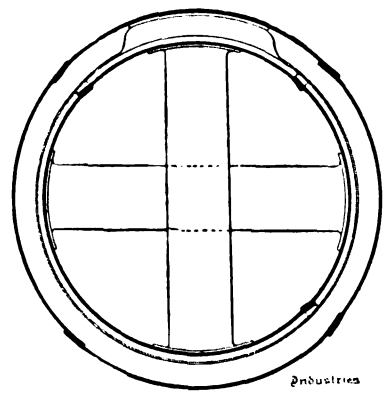
in our exports of pig iron to the United States, and of 7500 tons in those to Italy. To India and the Argentine Republic is mainly attributable the satisfactory increase in the consumption of railroad iron, our exports to the United States having fallen off materially. We have frequently pointed out the need for British iron masters to look to other fields than America for future demand. The "cornering" operation of the copper syndicate has largely increased the value of our exports of that metal, as compared with January, 1887. It is with much satisfaction we record the continued advance in our export coal trade. In spite of the great development of mining properties on the Continent, the volume of our trade increases, and France, Italy, and Germany continue to draw on our resources on a large scale. In 1887 we sent to those three countries over ten million tons of English coal. On the whole, then, there is no reason to be disappointed with the result of our export trade in the first month of the current year. It is with somewhat gloomy feelings, however, that we turn to a contemplation of the present position of industrial affairs at home, so far as the trades under review are concerned. The price of Scotch warrants is once more below 40s., and stocks in Connal's stores are increasing. In the North of England prices of both crude and finished iron are flat, and in that district, too, the requirements of consumers are below the capacity of production. In the Midlands a total collapse has taken place, and sellers are as much in the hands of their customers as before. It may turn out that this is but a temporary check on the progress of revival, the influence of which might in that case be beneficial; but, in face of the enormous stocks at different centres, and of the margin of productive power at present lying dormant, but which recent experience demonstrates will be brought into operation should improved prices obtain, it is difficult to adopt the optimist opinions promulgated in the general press.

Letters to the Editor.



THE BOARD OF TRADE INSPECTORS AND GREEN'S ECONOMISERS.

TO THE EDITOR OF "INDUSTRIES."



SIR,—That my letter which you kindly published in your issue of the 27th January, should have drawn forth the very suggestive and important letter from "Boiler," published in your issue of the 3rd inst., in relation to this subject, and also with regard to the Boiler Registry and Inspection Bill, is to me a subject of much pleasure; still the issues raised by the engineer-in-chief, Mr. Traill, and his assistant, Mr. Woodthorpe, in relation to the use of Green's economisers, are so important, both with relation to the questions of economy of fuel, and also of safety to life and limb, that I should like to have seen either some attempt at defence on their part, or, what would have been still better, an honest, straightforward, manly admission of error. That these gentlemen have written a report to the Board of Trade, which has been published with the weight of all its authority, and which will, consequently, have great influence and effect with the public, without sufficiently considering either the accuracy of their statement or the injurious consequences which might arise from them, will, I think, be admitted by all those whose opinion is of any value on the subject.

My reason for again referring to this report, is that probably ere long the whole steam-using public will be subject to the dictation of these Board of Trade inspectors. It therefore behoves everyone interested to carefully inquire what will be the result; and, in forming a fair estimate, we have no safer and better criterion than the work they have already done. It is therefore requisite that a sharp and searching scrutiny of each report should be made. It is much to be regretted that so much time is lost in presenting these reports to the public, as usually all interest in the particular explosion reported upon has been lost, and the event entirely forgotten long before the Board of Trade inspector's report is published. It becomes, therefore, of little interest, and the value of its deductions and assertions excites no attention.

For my purpose, let me explain here that Green's economiser is an arrangement of vertical pipes through which all the feed water used by a boiler is passed. It is placed in the external main flue of the boiler, which is enlarged for the purpose, and the heated gases, which have entirely left the boiler, and which are then on their way to the chimney, are passed through it. Every degree of heat, therefore, which may be taken up by the feed water while passing through a Green's economiser, is obtained from waste gases which would otherwise have passed directly up the chimney; consequently every degree of heat added to the feed water is produced without any cost of fuel, and reduces in exact ratio the weight of fuel consumed under the boiler. In the report under consideration, viz., No. 242, Mr. Woodthorpe says: "The temperature of the feed water after it had passed through the economiser was from 240°F. to 300°F., the average being about 280°F.," that is, a temperature corresponding to about 35lb. gauge pressure was imparted to the whole of the feed water passed into the boiler. Yet in the face of this, his own statement, he can go on to say that by discontinuing the use of this "so-called economiser," and "easily working all the boilers at once, the owners would effect a substantial saving." Should not consideration have been given to the well known fact that thousands of boilers, not only in Great Britain, but upon the Continent and also in America, are fitted with these economisers, and that they have been in daily use from twenty-five to thirty years, and further inquiry made before making such sweeping statements as are contained in this report? Had such inquiry been made, the overwhelming mass of evidence which could have been obtained, not only as to the economy effected by Green's economisers, but also as to their safety, would have been sufficient to convince, it is hoped, even Board of Trade inspectors.

SECTIONAL ELEVATION.

PLAN THROUGH A B.

I propose to refer to another case. On the 31st October, 1885, Mr. Peter Samson, a Board of Trade inspector, reported upon a preliminary inquiry (No. 145) which he made into the cause of a steam crane boiler explosion that took place at the West India Docks, London, on the 5th of the same month. The boiler was of the ordinary wrought iron vertical type, with cross tubes in the fire box, and a vertical up-take, as per above sketch. The cylindrical portion of the shell was $\frac{7}{16}$in. thick, 4ft. diam., and 7ft. 4in. high, exclusive of the part forming the ash pit. It was made of four plates arranged vertically, the seams lapped and double riveted with $\frac{3}{4}$in. rivets, 2in. pitch. The crown of shell was in one plate dished, flanged, and single riveted to shell. The fire box was slightly conical, about 4ft. high exclusive of the crown, 38$\frac{1}{4}$in. at the top and 40$\frac{3}{4}$ in. at the bottom, internal diameter. It had been originally made of four plates arranged vertically, lap jointed, and single riveted. The lower end had been in the first instance worked out to join the shell, but had been altered and fixed to a ring shaped thus, ⌐, of the same width as the water space. The side at the firing hole was worked outwards to the extent of 2$\frac{3}{4}$in., and joined to the shell, with a thin distance piece between, by single riveting. The crown was made in one plate, dished, flanged, and single riveted to the top of the fire box. There were two 8in. welded and flanged cross tubes in the fire box, placed at right angles to each other. The uptake was 12$\frac{1}{4}$in. at the top and 10$\frac{3}{4}$in. at the bottom in diameter, and secured to the crown of shell and top of fire box by angle iron rings. This boiler was made in 1872, and was about thirteen years old. The safety valve was loaded to 49lb. per square inch, and consequently usually worked at about that pressure; but, as Mr. Samson observes, "the safety valve was in a position favourable for fouling ropes, &c., when the crane was being swung." The evidence led Mr. Samson to the conclusion that the explosion was due to the collapse and "rupture of the fire box, apparently from over pressure, but how the over pressure arose there is no conclusive evidence to show." The inference, however, being that the "favourable position of the safety valve" fulfilled its expectations, and being fouled by some rope or ropes became inoperative, or at least so deranged, that a sufficient pressure to collapse the fire box was possible.

Mr. Samson, in reviewing the evidence given before him, further says: "As regards overheating, there is no sign of it, and it was stated by the inspector of the Manchester Steam Users' Association that the fire box was in good form when last examined by him thirteen days before the explosion occurred. The fire box plates are, however, thinned by corrosion on the fire side, and are only $\frac{1}{4}$in. thick in places, but the mean thickness is quite $\frac{5}{16}$in." .... After some further remarks, Mr. Samson again states that "the thickness of the fire box plates for the purpose of calculating the collapsing pressure may be taken at $\frac{5}{16}$in., and if that thickness be used in the formula

$$\frac{266{,}760 \times T^2}{(L+1) \times D} = P$$

where T = the thickness of the plate in inches;
L = the length of the fire box in feet;
D = the diameter of the fire box in inches;
P = the collapsing pressure in lbs.;

the collapsing pressure is found to be 106lb., or 2·16 times the normal pressure on the safety valve." This formula "is that given in the Board instructions to surveyors, with the constant multiplied by 4·94, which is the mean factor of safety possessed by two fire boxes with cross tubes, that were tested to destruction by cold water pressure."

It is to this formula, which we have Mr. P. Samson's authority for stating "is that given in the Board of Trade instructions to surveyors," that I venture to direct attention. It is generally assumed that there are about 150,000 boilers in the kingdom, and Lord Stanley, when moving the second reading of the Boiler Registry and Inspection Bill, in the House of Lords, on the 15th August, 1887, said that about 70,000 of these were under inspection and insurance. From the tables and statistics published by the various boiler insurance companies, it appears that somewhat over 15 per cent. of all the boilers under their inspection are of the vertical type, such as the boiler in question. It will therefore follow that about 25,000 boilers are subject to decision as regards the strength of their fire boxes by this formula. When we consider that by the ordinary rules which are adopted by boiler makers for this type of boiler, the collapsing pressure of the fire box would be more than four times that it is stated to be by the Board of Trade official calculation, some faint idea may be formed of the inconvenience, loss, and expense which will be thrown upon steam users by the enforcement of this one instruction alone to the Board of Trade surveyors. Every day large numbers of such boilers are being made and set to work, being almost universally in use by small steam users, and for such purposes as the case now before us, it is therefore a question of the highest interest and importance, for should the Board of Trade formula prove correct, the great majority of the boilers of this type are working in a dangerous manner, many at double and treble their safe working pressure.

By the Board of Trade formula it will be seen, taking the usual—that is, the most generally accepted—factor of safety, viz., four, that the boiler in question should not have been worked beyond $\frac{106}{4}$ = 26·5lb., whereas the safety valve was loaded to 49lb., and had been so for thirteen years, at which pressure the factor was then only 2·16. By the same formula, the collapsing pressure of this furnace when new would have been 141lb.; and consequently even then, with a safety valve loaded to 49lb., it had only a factor of safety of 2·89, instead of 4·94, with a safety valve load of 28·6lb., as demanded by the Board of Trade instructions. Does any competent engineer believe that a fire box only 4ft. high, 38$\frac{1}{4}$in. and 40$\frac{3}{4}$in. diam. respectively at the top and bottom, made of $\frac{5}{16}$in. plate, and stiffened by two 8in. welded and flanged tubes, placed at right angles to each other, would collapse at 141lb. pressure? Would any such engineer hesitate for one moment to subject a fire box of similar construction and dimensions to a test of that amount by hydraulic pressure? Would any fear of permanent injury to it in form, or even fear of producing leakage, deter him? If Messrs. Samson or the Board of Trade will have a similar boiler made, with a fire box exactly of the same construction, and test it, they will find that the fire box will not collapse at 141lb., according to their formula, and that 200lb. per square inch will fail to cause the slightest sign of weakness. I have no hesitation in saying that if a few of the boiler makers who are habitually turning out such boilers every day will give us the result of their daily experience, that we should find that hundreds of such fire boxes have regularly been tested to beyond their collapsing pressure by this Board of Trade rule. Having Report No. 242 before me, I am not surprised to find that this formula, given as a Board of Trade instruction to surveyors for the strength of fire boxes of vertical boilers, should be admittedly based on "the mean factor of safety possessed by *two fire boxes* with cross tubes, that were tested to destruction by cold water pressure." Upon this experience of two fire boxes Mr. Samson, or, rather, the Board of Trade, has presumed to base a formula, which will affect in this kingdom alone about 25,000 boilers. It is as purely empirical, misleading, and objectionable as Messrs. Traill and Woodthorpe's pronouncements in regard to Green's economisers, and apparently based on about the same amount of practical knowledge and experience.

The final observations of Mr. Thomas W. Traill, engineer-surveyor-in-chief, upon the report of the preliminary inquiry No. 145, are so truly ingenious and refreshing, that I cannot refrain from quoting them in conclusion. I trust they will be as amusing to your readers as they have been to me; they run thus: "The safety valve, considering the circumstances, was not constructed in a manner which can be considered satisfactory; the pressure at which the boiler was worked was too great for the thickness of plates in the fire box; consequently, with an unsuitable safety valve and a weak plate, we cannot be astonished at the explosion. *The strength of such fire boxes ought to be known by this time; and if the plates had been drilled they would have probably been found thin, as they turned out to be.*" The italics are mine.

Any words of mine would lamentably fail to do justice to the truly Dogberrian wisdom of the last "observations" of the surveyor-in-chief, and I will leave it to be judged upon its merits.

I shall be glad if any of your readers who may have evidence

Digitized by Google

as to the test or collapsing pressure "of such fire boxes" will give it. It would be interesting as well as useful at this juncture, when Board of Trade engineering appears to be endeavouring to re-enact the part of the "lean swine."

Yours, &c.,

Manchester, 13th February, 1888. ECONOMISER.

THE BOILER REGISTRY AND INSPECTION BILL.

TO THE EDITOR OF "INDUSTRIES."

SIR,—The letter of your correspondent "Economiser," in your last issue, appears to me to be far too sweeping in its condemnation of the above Bill, which he can hardly have read, or he would not be so much astray in his statements. Inspections, under the proposed new Act, need not be made by the Board of Trade officials themselves, as the Act (clause 8, par. 2) reads: "Any society, company, or body of persons, whose rules for the survey of boilers are for the time being approved by the Board of Trade (in this Act referred to as an approved boiler inspection society) may from time to time appoint surveyors under this Act," &c. This practically leaves the inspection of steam boilers as it is at present, viz., in the hands of the various boiler inspection associations; but it also provides that *all* steam boilers shall be periodically inspected by some one. After an experience of some twenty-three years amongst boilers, this is a course I heartily approve, as it will do something towards preventing explosions, whilst the Acts in force now simply order an inquiry *after* a fatal accident has occurred. Your correspondent will probably not deny that thousands of boilers are in use that ought to have been on the scrap heap years ago, and that many accidents have been brought about through the parsimony or the criminal carelessness of the owners, combined, in some cases, with the gross ignorance or carelessness of the attendant. In addition to compulsory inspection, I have long advocated that all boiler attendants should possess a certificate of competency that they are capable of undertaking the work. This would prevent day labourers being made to do duty in this connection. A step in this direction has recently been taken by a Scottish boiler insurance company, and certificates of competency are also granted in America, Germany, and some of the Australian colonies. I do not wish it to be understood that I am advocating Board of Trade inspections, as it is more than probable that if the work were undertaken by independent insurance associations it would be much better done than if undertaken by a Government department, which would have no particular interest in the boiler, and would not be liable in any way if the boiler did explode. The proposed Bill as it at present stands is not by any means complete, and contains one or two extraordinary clauses, for instance clause 9, that certificates shall be granted to the boiler owner, "and the period stated therein as the period during which the boiler may be safely used shall not exceed twelve months or *any less period* specified in the declaration of fitness." I take it he would be a clever boiler inspector who would dare to say a boiler is fit to work six months, not to say twelve months. If it is not safe to work it for twelve months it cannot be safe to work it at all. In case boiler inspection were made compulsory, the great increase in business would probably provide sufficient funds to enable the various associations to make a thorough examination of every boiler in the kingdom once a year. In France and Germany Government boiler regulations are in force, which place the manufacturer as well as the boiler owner under restrictions as regards the construction and setting of the boiler in the first place, and afterwards as regards its periodical inspection and testing. I think a Bill enforcing compulsory inspection of steam boilers, and the granting of certificates to competent attendants, could be introduced without causing undue friction or interference with the rights of boiler owners, and by making use of the machinery of some of the present boiler insurance associations, this inspection could be carried out at a very moderate cost. Yours, &c.,

THE AUTHOR OF A "HAND BOOK FOR STEAM USERS."

London, 13th February, 1888.

ENGLISH AND AMERICAN PRACTICE IN ELECTRICAL ENGINEERING.

TO THE EDITOR OF "INDUSTRIES."

SIR,—May I be permitted to correct a statement in your last issue, in which I am reported to have said, in the discussion on Mr. Geipel's paper, "that both in science and practice the Americans led the way." As this will convey an impression contrary to my meaning, I send you copy of my notes, which, though I did not read from them, is, I believe, word for word what I said:—

"On page 1 the author says: 'On the other side of the Atlantic, although the science of electricity is much behind, the practice is far ahead of our own.' I wish to take exception to the word 'much.' Though I cannot admit that American scientists are superior to our own, seeing we have such men as Thompson, Preece, Hughes, Hopkinson, Kapp, and many others who are bad to beat, still, when we look fairly, it is going a little too far to say that our American cousins are *much* behind; we must remember Franklin and Edison, Houston, Thornton, Brush, and a host of others, who are not children in science. I wish also to emphasise, that in practice they are far ahead of us, and I think we may profitably ask, why? We are behind not merely because our laws and monopolies are against us, but from the conservatism which is our national characteristic. Perhaps our scientific attainments are a hindrance. We go looking at, and round and about, searching into, and turning inside out, and not finding perfection, do nothing; whilst they see a way, perhaps not the best way, they do it, it works, they are satisfied. The American takes what is, the Englishman waits for something better." Yours, &c.,

M. HOLROYD SMITH.

Halifax, 10th February, 1888.

STEAM HEATING COMPANY.—The Hussey Re-heater and Steam Plant Company, New York, has been incorporated, with a capital of £20,000; its object is to supply hot water, hot air, and steam for motive power.

CLYDE SHIPBUILDING FOR JANUARY, 1888.

LAUNCHING in January is usually light, and this year has been no exception to the rule. The heavy booking of orders during the autumn and early winter months seems to have exhausted the demand, and few orders have in consequence been added to the books of local firms during the month. The orders booked during the month have included two steamers of 5000 tons each, to be built by Messrs. Denny Brothers, Dumbarton, for the Transatlantic Company of Barcelona; a steamer of 3000 tons, to be built by Messrs. Stephen & Sons, Linthouse, for Messrs. Dunlop and Sons, Glasgow; two vessels of 4000 tons each, for the British India Steam Navigation Company, to be built by Messrs A. & J. Inglis. The new tonnage ordered during the month reaches upwards of 20,000 tons.

The following vessels were launched in January, making a total of twelve vessels and 13,056 tons: No. 199, steel screw steamer, 5000 tons and 5000 i.h.p., built on builders' account, by Messrs. A. & J. Inglis, Pointhouse; "Amber," steel, 1050 tons and 1450 i.h.p., for the Eastern Telegraph Company, by Messrs. Robert Napier & Sons, Govan; "chaloupes," Nos. 36, 37, and 38, each 40 tons and 65 h.p., for the Panama Canal Company, by Messrs. Lobnitz & Co.; "Flying Cormorant," steel twin screw tug, 260 tons, for the Clyde Shipping Company, built by Messrs. Robert Duncan & Co., Port Glasgow; "Lady Ailsa," steel, 1250 tons and 600 i.h.p., for Messrs. J. & A. Wyllie, Troon, built by Messrs. The Ailsa Shipbuilding Company, Troon; "Lady Weld," steel paddle steamer, 511 tons, built by Messrs. Scott & Co., Greenock, for the Netherlands India Steam Navigation Company; "Nefiche," hopper barge, 400 tons and 300 h.p., for the Suez Canal Company, built by Messrs. Lobnitz & Co., Renfrew; "Ocean," 2800 tons, for Messrs. Hermann, Stursburg, & Co., built by Messrs. Russell and Co., Greenock, engines by Messrs. Duncan Stewart & Co., Glasgow. Sailing vessel, "Sutlej," 1660 tons, for Messrs. Foley, Aikman, & Co., London, built by Messrs Russell & Co., Greenock. Lifeboat, 5 tons, built at Irvine.

Reviews.

A HAND BOOK FOR STEAM USERS. By M. Powis Bale. London: LONGMANS, GREEN, & Co. 1887.

Some years ago, the author published a chart of rules to be hung in engine rooms for the guidance of engine drivers. The work before us is an amplification of these rules, with chapters on steam engine and boiler management and steam boiler explosions added, in order to render them of service to steam users generally; and all the information is given in numbered paragraphs under appropriate headings. Chapter I., which contains rules for engine drivers and boiler attendants, requires no special comment; the directions are all clearly given, and of a thoroughly practical and common sense character. We note that the author recommends the use, wherever possible, of a damper worked by steam automatically, as it is certain in its action and independent of the boiler attendant. In Chapters II. and III., the management of steam engines and boilers is dealt with. With respect to the remedies for incrustation in steam boilers, the author gives various recipes, but is careful to state that he does not guarantee their success; to tannate of soda he appears, on the authority of Dr. Joseph Rogers, of Indiana, to give the preference, and explains its chemical action in purifying water of carbonates of lime and magnesia. Instructions are also given for testing feed water for lime or acid in cases where it is not practicable to get a proper analysis made, but the author recommends the latter course whenever possible.

Want of space prevents our noticing in detail the various matters treated in this book, but a few of the headings will give a fair idea of its scope and aim. Among those relating to boilers are: Water gauges and test cocks, covering steam boilers and pipes, water circulation in boiler, plugging leaky tubes, firing steam boilers, &c. Rules are given for the dimensions of boiler chimneys, and a short table of the proportions of the latter for boilers of various horse power, according both to the American system and the Armstrong rules. The work also contains a useful table for calculating the volume of the steam or water space in steam boilers. In connection with steam engines, there are paragraphs on: Pounding and knocking of engines, piston rod packings, sight feed lubricators, and hot crank pin bearings. Although the author enumerates the causes of knocking in engines, we notice that he does not attempt to give instructions how to ascertain where the knock is. This, as every practical engineer knows, is by no means always easy, and can in many cases only be done by the exhaustive method. In Chapter IV., the various causes of boiler explosions are enumerated and discussed in succession. The author's remarks should be carefully read by all owners of boilers and those in any way responsible for their management. He is in favour of a compulsory system of boiler inspection, and of granting certificates of competency to those having boilers under their charge. Altogether, we can recommend Mr. Bale's work to those for whom it is more immediately intended; and we also think that it might be studied with advantage by engineers and draughtsmen who have to design boilers, for, as experience proves, defective design is answerable for many of the ills to which steam generators are subject, and can only be avoided by careful attention to the various important practical details to which it is part of the author's purpose to draw attention. The fact that this little book has just seen a second edition is sufficient proof of its practical value.

THE BRASS FOUNDERS' MANUAL. By Walter Graham. Seventh Edition. London: CROSBY LOCKWOOD & Co.

This work forms one of Weale's Rudimentary Scientific and Educational Series, and the fact of its having arrived at its seventh edition shows that it has been found useful by those engaged in brass founding. After some brief instructions with regard to the general arrangement of a brass foundry, the apparatus and material for moulding are dealt with, and Mr. Graham here takes the opportunity of giving a few words of sensible advice to workmen on the subject of the benefit of labour saving machinery, though it is doubtful whether the enunciation of the principles of political economy will suffice to dispel the prejudices of the less educated among the working classes. Instructions are given on alloying, turning, filing, burnishing, soldering, and other processes connected with the trade. The book also contains a classified list of most substances used by brass founders, with a brief description of each. Besides the various useful tables contained in former editions, there have now been added a table of the new Imperial Standard Wire Gauge, prepared by the Iron and Steel Wire Manufacturers' Association, and a table giving the properties of materials, such as specific weight, melting point, contraction, strength, hardness, &c. Where necessary to explain the author's meaning, simple illustrations are supplied.

WRIGHT'S AUSTRALIAN, INDIA, CHINA, AND JAPAN COMMERCIAL DIRECTORY AND GAZETTEER. 1888-9. New York: GEORGE WRIGHT. London: WATKINS AND OSMUND, 6, Ludgate Hill.

This bulky volume is intended as a hand book of the trades, professions, commerce, and manufactures in the Australian Colonies, India, China, and Japan; and, in view of the rapid increase of our business relations with those countries, will prove useful and supply a long felt want. It contains several useful maps, made expressly for this work by Mr. Gaylord Watson, the well known map maker, of New York; and, for the convenience of traders, a list of the leading British and American exporters and manufacturers is appended. At present comparatively little is known by the majority of British traders of the vastness of our Australian dependencies, their commerce, progress, and growing civilisation; affording as they do a new field for our manufactures, and much valuable information is contained in the present volume which will tend to make these facts better known. Thirty years ago Australia and New Zealand were scarcely known to the commercial world; at the end of 1884 the imports amounted to upwards of £64,000,000 sterling, the exports, consisting chiefly of raw products, exceeding £51,500,000. It is claimed that this is the only directory which gives a full history of all the trades and professions in all the Colonies in a compendious shape, and the publisher states that the bulk of the information has been gathered on the spot, he personally having visited the several countries and the most important cities dealt with in the book.

Each country and colony is printed on different coloured paper, and has a separate index. The towns in each country are arranged alphabetically, and the name of each manufacturer, trader, or professional man is given under his town and calling. The following countries are included in the work: The Australian Colonies, Victoria, New South Wales, New Zealand, Queensland, South

Digitized by Google

Australia, Tasmania, West Australia, Fiji, India, Burmah, The Straits Settlements, Java, Siam, The Philippine Islands, Ceylon, China, and Japan. Australia and New Zealand together cover an area of over 3,000,000 square miles, and have a population of nearly 3,500,000, which is growing by emigration at the rate of 65,600 per annum, the difference between the birth rate and death rate being 66,000 per annum. There are over 686,000 scholars in the State schools, and the public revenue is upwards of £24,000,000, the public debt exceeding £140,900,000. There are 8049 miles of railway open, and 2333 miles now in course of construction, and 66,439 miles of wire are in use for telegraphic purposes. The live stock in March, 1886, was estimated at 1,327,806 horses, 8,264,994 head of cattle, 84,222,262 sheep, and 1,129,851 pigs. These figures will give some idea of the growth of this particular portion of our Colonies. For many years after the discovery by Captain Cook in 1770, we used the country as a penal settlement, but this prevented free colonisation and the healthy development of the community; now we have grown wiser, and keep our convicts at home, extending our markets, and providing a new outlet for our manufactures and surplus population. Australia is rich in minerals—gold, copper, tin, iron, and other metals having been found—in addition to extensive coal deposits. These will insure for the country a great future in manufactures, though at present it chiefly relies on sheep, cattle, horses, grain, and sugar. For each country a large amount of useful information is given on the history and development of the country, its geology and physical features, its divisions into districts, and details of its population, together with statistics relating to the population and industries of such district. Particulars are also given of the government departments, the postal regulations, and the Customs duties, and under the heading of each town much important information is given. The maps are large, drawn to a good scale, and show the railways, mail and coach roads, as well as all the towns and cities. It is interesting to learn that Fiji, one of the latest territories annexed to the British Crown, comprises about 255 islands and islets, about one hundred of which are inhabited, the population consisting of about 2700 Europeans and 140,000 natives. The principal towns, Suva and Levuka, are fully described, and a classified list of their inhabitants is given. The British Empire in India, with its area of 1,486,319 square miles, and population exceeding 257,000,000, is treated separately, its chief towns being arranged alphabetically. The Chinese Empire, most of which is imperfectly known, as it is practically closed to foreigners, has an area of 1,535,000 square miles, and a population of about 405,000,000. All the treaty ports are fully described, and given in alphabetical order. Japan, a country probably as ancient as China, but which has shown a remarkable capacity for development and the adoption of Western ideas within recent years, has a population of about 37,000,000. The Government has shown a progressive spirit in recent times, and the advance of the country in arts and science has been great. Education has made rapid strides; gas, steam, electricity, railways, and machinery are all eagerly adopted by the Japanese. The first Japanese railway was opened in 1872; now there are several hundred miles of railway open, and about 5000 miles of telegraph lines. Much useful and interesting information is given respecting the country, and the principal towns are fully described in alphabetical order. The book is well printed, and conveniently arranged, and will form a useful reference volume for the merchant's office or counting house.

SAFETY LAMPS IN COLLIERIES.*

On a fine summer's day the sun expends an average of 1 h.p. on every 30 square feet of the earth's surface in this latitude, or 1450 h.p. per acre. This great gift of energy is neither utilised nor stored by man at present, though Nature presents us with some of it in waterfalls and flowing streams. The sun itself has been more generous. Ages upon ages ago it shone with resplendent glory on a grand luxuriant flora of a uniform but flowerless character in a climate warm and damp. England formed part of a tropical jungle or swamp, where grasses, mosses, ferns, and sedges, *coniferæ*, *araucariæ*, *equisetæ sagittariæ* grew and flourished, perished and fell *in situ*, to be covered up by following geological formations and compressed into those grand seams of coal that form now the principal source of England's greatness and wealth. If language be fossil poetry and words condensed history, then coal may be derived from *coelum* or κοίλος (*koilos*), and imply a Heaven's sent gift. The first authentic account of coal digging dates from the reign of Henry III., when Newcastle sent its first cargoes by sea to London, and thus gave the mineral the name of *sea coal*. Early records of the output of coal are wanting. In 1700, it was 2,614,000 tons: in 1800, is was 10,000,000 tons; in 1850, it reached 42,000,000 tons; in 1886, it reached 157,518,482 tons. A ton of coal occupies very nearly a cubic yard of space. Hence this quantity of coal, if placed in Hyde Park, would form a mountain as high as Snowdon, and if erected as a wall around the coast line of Great Britain it would be 6ft. wide and 30ft. high. It would form a girdle round the world 3ft. wide and 12ft. high. We extract from the earth twenty times more energy than the sun can possibly restore to it by the growth of forest, and we are gradually, but surely, tending towards the time when this store of power, heat, and light will be exhausted, when our busy hives of industry must seek other shores, and when England will perhaps become a summer resort for a wealthy Anglo-Saxon race occupying other quarters of the globe. Coal is not only, like knowledge, power, but, like the precious metals, it is wealth. The average price of coal at the pit's mouth in 1886 was 5s. per ton, and thus its total value was £40,000,000; but when we consider the average price paid for it, we must double, if not treble, this lump sum. The number of collieries open was about 3500, and since it costs £100,000 to open a colliery 2000ft. deep, when we think of the railways, the canals, the ships, the shops, the marts employed for its transit and its distribution, we can only conclude that the capital embarked in this industry must equal, if not exceed, the National Debt. The hewing and raising of coal is unquestionably a dangerous occupation. "The price of coal is pitmen's lives," said an old collier to George Stephenson. Five hundred and twenty thousand persons are employed in our collieries, and the output per person is 308 tons. Nine hundred and fifty-three persons met their deaths in 1886; but it is satisfactory to know that a miner's life is more than twice as safe now as it was thirty years ago. The number of persons employed per death was—in 1856, 242; in 1886, 545. The number of tons raised per life lost was—in 1856, 64,700; in 1886, 188,800. Most people, if asked what was the principal cause of this loss of nearly 1000 lives, would answer explosions of fire damp, but this would not be true. The principal cause of accident is falls of roof and sides. In 1886 there were from falls of roof and sides, 461 deaths; explosions, 129; trams and tubs, 81; and miscellaneous, 282. Thus falls of roof form 41 per cent. of the whole, and explosions 23 per cent. Explosions attract immense attention, from their publicity and their appalling suddenness and magnitude. It is dreadful to take up a morning paper and read of 268 fellow creatures engulfed, as at Abercarne in 1878, or 164 at Seaham in 1880; but the daily and steady loss of life by ones and by twos fails to get chronicled, and passes unheeded in the same way as the great majority of the 20,000 violent deaths that occur in these islands every year. All mines are required to have two shafts—one the intake or downcast, the other the return or upcast, and the workings are so interlaced with ways and roads, doors are inserted here and there to direct the current; anemometers are used to measure its rate of flow, that any ordinary inroad of gas is swiftly swept away. Fire damp, or pit gas, is marsh gas (CH_4). It oozes out gently from the exposed seam, or sometimes it bursts out through some fissure with great force, forming what are called "blowers." If it be mixed with air, in the proportion of from 5 to 9 per cent. of gas, it becomes highly explosive, and is the prime cause of those fearful disasters that have made coal mining so terrible. In gasless mines, candles always have been and still are used; but in early days, in foul places, men had frequently to work in the dark, or to be content with the feeble illumination of the phosphorescence of decaying fish. It is remarkable how the eye adapts itself to feeble light, and in the Cimmerian darkness of a coal mine even phosphorescence has a useful illuminating effect. In many places they used the steel mill; a disc of steel rotated rapidly against flint, giving light by the shower of sparks thrown down. It is most remarkable that no scientific thought was devoted to this subject until 1815. In 1813, Dr. Clanny, of Newcastle, had devised a very poor lamp, the air to support which was driven by bellows through water; but in 1815 Sir Humphrey Davy devoted his powerful mind and skilful hands to solve the question, and speedily invented in this very Institution his immortal safety lamp. It is a remarkable coincidence that in the same month another powerful but untutored mind, by strong observant powers and pure mechanical reasoning, had arrived at very nearly the same result; and even to this day the affectionate remembrance and name of the eminent Northumbrian brakesman, George Stephenson, is maintained by the use of the "Geordie," in his old home, the Killingworth Colliery. Davy's classical paper was read before the Royal Society, on November 11, 1815, and was entitled, "On the Fire Damp of Coal Mines; and on Methods of Lighting the Mine so as to Prevent Explosion." He showed that flame would not pass through small tubes and apertures, and how in comparatively still air, however charged with gas, a wire gauze surrounding the flame so reduced the temperature by radiation that explosion was impossible. Ingress of air and egress of products of combustion are resisted. He showed that a flame so protected gave immediate intimation of the presence of gas by burning dimly, and by becoming capped with a blue flame, or *aureole*, that though the wire gauze became red hot, it still radiated away the heat sufficiently to prevent its reaching the temperature point of explosion. He also pointed out, which has been strangely neglected, until enforced recently by the Royal Commissioners on Accidents in Mines, that it failed to act in a current of air, but that this effect of currents could be diminished by shielding or protecting the inlet of air. The main principle discovered by Davy is the basis of all safety lamps burning oil or spirit, but several departures in form have been proposed at different times. The "Geordie" is in reality a Davy lamp with a glass shield. The "Jack" lamp is a Davy in a tin can. The "Clanny" is a Davy lamp with the flame portion surrounded by a thick glass cylinder to increase the emission of light, and now with a bonnet or shield to protect it from currents of air. The "Mueseler," or Belgian type, is a "Clanny" with a central metallic cone acting as a funnel to increase the draught, and therefore the light. The "Marsaut," or the French type, is a bonneted or protected "Clanny," with two and three gauzes added to increase the security. The number of lamps is legion. A new intake here, a fresh egress there, a new direction to the currents of air feeding the flame, a change in the form or character of the wick, a lock, a different form of pricker, a shut-off or extinguisher (automatic or manual), is quite sufficient to justify a new patent and a new name. The Royal Commission experimented upon 250 different kinds of lamps. Since the commencement of the year a new Act has come into force rendering it unlawful to use the plain "Davy," "Stephenson," or "Clanny" lamp in mines where safety lamps are necessary. They must be shielded, and great numbers are being converted into bonneted "Marsauts" and "Mueselers." They are also being constructed to burn the best vegetable oil (rape or colza), to which one-third mineral oil is added, as recommended by the Royal Commission, to enhance the light giving power of the lamp. These converted lamps have baffled all attempts to explode them in currents of explosive gases of very high velocity, and under the most rigid tests. There are several objections to these oil lamps. They go out, or are put out when danger exists; they render that most important and essential duty, examination of the roof, difficult and insufficient. If they become extinguished by accident or design, much time is necessarily wasted in getting them re-lighted, an operation that must be done at or near the shaft, perhaps two miles away from the working face, and which therefore reduces the output of coal and the earnings of the collier. The light they give, even at the best, is very small—about one-third to half of a candle. There are several dangers present. The Royal Commission said: "The source of light within the lamp should be unable under any circumstance at all likely to occur in working coal to cause the ignition of an inflammable mixture of fire damp and air, even when this is passing at a high velocity." But glasses break by water, heat, falling coal, and accident. Joints get loose and bad even when protected by asbestos washers. They prove a constant temptation to the thoughtless and callous to get a light. The perfect light does not exist at present; but while these mechanical lamps are very excellent in their way, electricity seems likely to step in and supply their deficiencies and fill a decided want. An electric lamp can be made to give any desired amount of light; but anything between half a candle and a candle seems easily attainable, and such a light can be maintained steady and bright in explosive gases and in strong currents of air. They are simple in construction, easy of inspection; they are not likely to be extinguished in handling, like the Mueseler; but they do not act as detector of the presence of gas, and they might explode gas if their protecting glass shield were accidentally broken. It is remarkable that Davy himself in 1815 experimented with an arc lamp in a closed vessel of glass, but it was not until 1865 that a practical lamp was proposed for collieries. Dumas and Benoit used a small Geissler tube illuminated by sparks from an induction coil and excited by a primary battery; but it was heavy—it was a kind of knapsack to be carried on the back, and it met with no success. Mr. Swan has been more successful. The great success of the glow lamp, in the introduction of which he has played so prominent a part, and the perfection of the secondary battery, have enabled him to produce a lamp that compares in weight and size and light with the best mechanical lamp. Eight hundred of these lamps are in constant use in the National Colliery in the Rhondda Valley in South Wales, and one thousand six hundred more are on order for the Risca and Abercarne Collieries, belonging to Messrs. Watts, Ward, & Co. They are giving great satisfaction. A collier told me that the electric light was "as good as the moon." The lamp batteries are charged a great number at a time in blocks at the pit bank. Mr. Pitkin has also been very successful in making light portable lamps, and they have been practically used in Cannock Chase and at the Tyldesley Collieries in Lancashire. The "Sun" lamp is another very promising form, worked by secondary battery. It is light—3lb. 12oz.; it gives 1¼ candle, and this is maintained for ten hours. Secondary cells usually require about twelve hours charge to emit a ten hour discharge, but this cell will give a ten hour discharge with four hours charge. It is fitted with a safety appliance—a plan patented by Mr. Sennett in 1882—by which the lamp is automatically switched out the instant the outer protecting glass is broken or cracked, so that contact between the hot filament of the lamp and explosive gas is prevented. This safety appliance has been tested by Mr. Rhodes at the Aldwarcke Colliery in actual explosive mixtures. Many efforts have been made to introduce primary batteries for the same purpose, but up to the present moment I have seen only one—the Schanschieff—which in efficiency, lightness, and economy, comes up to the requirements of a safety lamp. A primary has this advantage over a secondary battery—that it is charged at once by an operation as simple as that of trimming a Davy. To trim a Davy means thorough cleaning, inserting a fresh wick, pouring in new oil. A primary battery means pouring out old and pouring in fresh solution. Occasionally zinc requires renewal, but all these operations are within the intelligence of the collier, and the lamps need not go to the surface. The simplicity of the operation has distinct merits of its own that compensate for the extra cost of the materials used. The chief charm of the electric lamp is not the greater light that it gives, but the power it gives the viewer to examine the roofs of the ways and workings; it is so extremely portable and handy; it can be put anywhere; the battery can be placed on the ground or suspended by a spike to a tree, and the lamp can be fixed in the cap or around the waist; it can be put anywhere and used anyhow. Mr. Sopwith, at Cannock Chase, has been taking heavy batteries to the working face, and using bright five-candle lamps in reflectors, so as to illuminate the working face with a light which in that region is comparable to daylight. The men are charmed with it. The chief defects of the electric lamps are their fragility, the liability of the carbon filament to break, the weight of the battery, and the absence of gas detection; and these defects have been very much enhanced by imperfect construction and injudicious details. Electricians have not spent sufficient time in the lower regions, and practical colliers have no time to go to the laboratory. When the two professions are properly amalgamated, we shall very likely obtain the true safety lamp. The electric lamp is not a fire damp detector, but an electrical appliance is easily added. Liveing and Swan have done this; but it is doubtful whether a more efficient detector than the Davy exists, and whether an apparatus that is so thoroughly understood, and so thoroughly practical, will be superseded for a purpose for which it seems so eminently adapted. I cannot conclude, especially in this place, with more pregnant words than Davy's own: "The gratification of the love of knowledge is delightful to every refined mind; but a much higher motive is offered in indulging in it when that knowledge is felt to be practical power, and when that power may be applied to lessen the miseries or increase the comforts of our fellow creatures."

* Abstract of a paper read by Mr. W. H. Preece, F.R.S., before the Royal Institution of Great Britain, 10th February, 1888.

PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING.

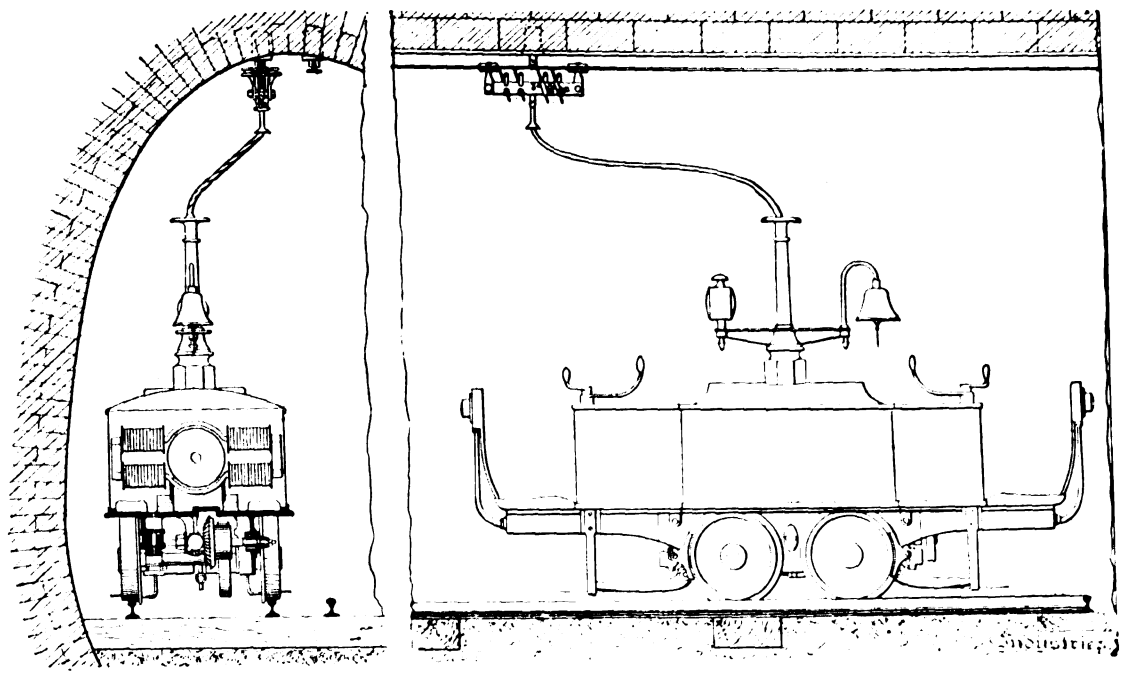

FIG. 2.—END AND SIDE ELEVATIONS.

PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING.*

(Concluded from page 149.)

Underground Haulage.—Electricity has been applied to haulage in various mines. A locomotive car, worked by a current sent through a conductor fixed along the side or the roof of an underground road, could be employed economically wherever the traffic is large and the distance considerable; but there is the objection of requiring a heavy locomotive car, in order to get sufficient tractive power for starting a train of tubs. In a colliery at Zaukeroda, near Dresden, power is generated above ground by a vertical engine, having a 10in. cylinder with 8in. stroke, which drives a Siemens dynamo. The current is led to the shaft, which is about 60 yards distant, by two bare copper wires; then down the shaft to a depth of 120 fathoms by well insulated conductors, to the T irons, which run along the roof of the waggon way and form the contact rails, as shown in Fig. 2. The current is picked off these rails by sliding contact pieces fixed to the locomotive, and is led to a switch, which can turn the full current either through the motor, or first through reducing resistances and then to the motor. A controlling switch with a seat for the driver is placed at both ends of the locomotive, so that perfect control of the speed and of the starting and stopping of the motor is provided. The length of the line is about 700 yards, and the gauge is 22½in. A train consists of about fifteen tubs, each carrying 10cwt. of coal; and the locomotive weighs rather over 30cwt. The journey takes from three to five minutes, the speed varying from five to seven miles per hour. The plant costs a little above £800, including steam engine, dynamo, motor, locomotive car, conductors, and accessories; it has been working successfully since 1882, and was supplied by Messrs. Siemens & Halske, by whom several other mines in Germany have since been similarly furnished. The working cost of hauling 660 tubs per day of sixteen hours is given by Mr. Rowan as follows:—

	s.	d.	s.	d.
Driver's wages	5	3		
Steam	2	3		
Engine driver at surface	3	1½		
Lubrication, &c.	1	1½		
			11	9
Interest and depreciation at 15 per cent. per year of 300 working days			8	1½
Total working cost per day			19	10½

For the output of 660 tubs or 330 tons per day this amounts to only about three farthings per ton.

Telpherage.—The plan of transporting material in skips on overhead wire ropes by means of electricity, introduced under this name by the late Professor Fleeming Jenkin, of Edinburgh, has not so great a field for its use in this country as it may have in less populous regions, because our roads are good, and railways generally near at hand, and we have abundance of water carriage. But in places where material has to be conveyed across hilly districts, or over bad roads, to the railway or water, it will be found more useful. It has been employed with considerable success for the past two years at Glynde, near Lewes, for transporting clay to the railway over a distance of 1600 yards; 270 tons are carried weekly at 7½d. per ton. In our larger cities a modification of this plan might advantageously be applied to alleviate the heavy street traffic. In the place of wire ropes, stiff girders might be used, the cars being suspended from wheels running along a rail or rails fixed on the girder. Such a railway would be economically constructed, in comparison, at least, with the expense of constructing an underground railway; and it would not have any great effect in obstructing the light from the streets, as is the case with elevated railroads for steam locomotives. A general idea of the present position of electric locomotion in Europe and America is furnished by Table IV., which is an abbreviation of one compiled in May, 1887, by Mr. T. C. Martin, President of the American Institute of Electrical Engineers.

III. ELECTRIC LIGHTING.

Of the four branches of electric engineering dealt with in this paper, electric lighting is the one which up to the present has received most attention, called forth the largest outlay of capital, and produced the most beneficial results, if not to so great extent in this as in other countries. Artificial illumination may be considered in the three aspects of comfort, convenience, and economy. As regards comfort, electric lighting proves itself superior to all other methods of illumination. For indoor lighting, the incandescent light may be utilised and toned down to suit almost any requirement. It may be brought near to any object requiring illumination, without occasioning the least inconvenience from heat or dazzle; or it may be far removed in the ceilings or cornices, without risk of fire, or of injury to the decoration. In short, it can be used in any position or for any purposes of illumination for which gas, oil, or candles are available, and for a great many for which they are not available. For outside illumination and large enclosures, the arc light gives a brilliancy and cheerfulness altogether unattainable by any reasonable expenditure of gas or oil. The convenience of the electric light has caused it to be highly appreciated, when it is found that by the mere pressing of a button a light is instantly obtained, which can be shaded over in any manner, without danger of setting fire to the fabric forming the shade. It also does away with the constant cleaning of globes or trimming of lamps. In respect of economy, the electric light does not as yet hold out the same decided advantages that it does in the other two respects just considered. In incandescent lighting, the cost of distribution is still heavy, though by increasing the e.m.f., and the efficiency of lamps, it is being much reduced. In arc lighting, the difficulty of sub-dividing and of reducing the amount of light given by one arc lamp, renders it expensive for general out door street illumination, as compared with the present low prices of gas and oil. For the lighting of main streets and railway stations, or other places where a concentrated light is required, the arc light is beyond question far cheaper than gas; and its cost per candle power is but a very small fraction of that of gas. As the use of electric lighting extends, the cost of working becomes reduced. Installations which four years ago cost 4d. per arc lamp per hour, are now costing only 2d. The chief saving has been in the items of carbons and attendance, though the increased efficiency and durability of the apparatus have also greatly contributed to the reduction. Four years ago, 11mm. or 0·43in. hard carbons cost 4d. per foot. They can now be obtained for 1½d. per foot, or less than one-third. The following figures supplied by the North British Railway respecting the actual cost of working their electric lights at the Waverley Station, Edinburgh, are interesting as showing how much cheaper it is becoming. The installation is worked by their own staff, and consists now of forty Brush arc lamps, supplied with a current of 10 ampères by a No. 8 Brush dynamo, which is driven by a semi-fixed engine.

July to December, 1884, thirty-three arc lamps, 41,884 lamp-hours.

	£	s.	d.
Wages	165	13	9
Repairs	47	2	6
Carbons	125	15	11
Coal	65	19	11
Oil, stores, &c.	27	15	0
Interest and depreciation at 10 per cent.	52	2	2
Equal to 2·77 pence per lamp-hour.	£484	9	3

July to December, 1886, thirty-nine arc lamps, 55,068 lamp-hours.

	£	s.	d.
Wages	195	17	6
Repairs	78	9	6
Carbons	62	17	3
Coal	23	14	1
Oil, stores, &c.	8	15	2
Interest and depreciation	41	10	6
Equal to 1·79 penny per lamp-hour.	£411	4	0

In conjunction with these arc lamps, they are running 148 Brush Victoria incandescent lamps, distributed in the refreshment and waiting rooms, and throughout the whole of the suburban station. For these the total number of lamp-hours for the half year was 171,251, and the cost was £83. 9s. 9d., including all contingencies, equal to 0·12 penny per lamp-hour. There were 113 lamps renewed, which shows an average life per lamp of 1515 hours.

Local Conditions.—The cost of incandescent lighting is especially variable, and affected by the local conditions of the installation. The chief of these are (*a*) the average number of hours of lighting each lamp, and (*b*) the average distance of the lamps from the generating station. The diagram (Fig. 3) shows

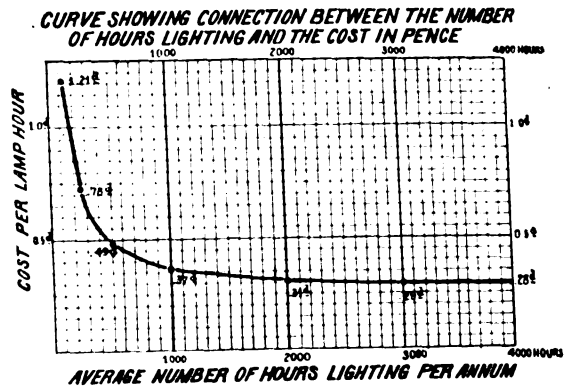

FIG. 3.

how the cost per lamp-hour varies with the number of hours the lamps are alight annually. Where the conditions are favourable, incandescent lighting can already compete with gas; and in a number of installations which have been superintended by the author a large saving is being effected. The following figures, kindly supplied by Messrs. George Jager & Son, show that the yearly cost of lighting their sugar refinery at Leith has been reduced from £347 with gas to £204 with incandescent lamps. The average life of the lamps is about 1400 hours each. The installation consists of 180 Brush Victoria lamps of 17 and 10 candle power, supplied by a self regulating Victoria dynamo, which is driven off the shaft that drives the centrifugal drying machines. The dynamo has been running night and day since it was started two years ago, without failure; it is started on the Monday morning, and runs continuously without stoppage till the following Saturday afternoon:—

				204	0	4
Saving per annum by electric lighting				£143	13	0

In the United States there is hardly a city or town of twenty thousand inhabitants which has not a central station for arc or incandescent lamps; and many towns of three thousand to four thousand are supporting them also. On the Continent large central stations for electric lighting are already in operation in competition with gas; but there the price of gas is generally two or three times what it is in this country. If the power is to be generated by dynamos and used direct, the cost of distribution on a large scale will probably never be reduced as low as with the existing gas supply; seeing that an efficiency of 95 per cent. can now be obtained with the dynamo, and that steam engines are not likely to be materially improved. It is therefore in the lamps that improvement is to be looked for, by making them with a higher resistance and greater efficiency. The accompanying Table V., which is an abbreviation of one previously constructed by the author,* may be interesting here as showing how the economical sectional area of conductor and the economical loss of potential vary for the different conditions of amounts lost in interest and depreciation on the conductors, and in horse power wasted in overcoming the resistance of the conductors. The question of conductors is one which must be left to a very great extent at the discretion of the engineer, in view of what are likely to be the requirements of each individual case; but when the conditions have been settled, Table V. is useful in showing at a glance the size and cost of the conductor, and the ensuing loss of potential.

Transformers.—These are at present receiving a large amount of attention. By their means small high tension currents of electricity, sent from a distant generating station along a small conductor with a comparatively small percentage of loss, can then be converted into large low tension currents for the supply of ordinary incandescent lamps. In some arrangements of

* Paper read before the Institution of Mechanical Engineers, on the 3rd inst., by Mr. Wm. Geipel, of Edinburgh.

* See *The Electrician*, 12th April, 1884, page 522.

Digitized by Google

these transformers the loss in conversion is not more than 5 per cent. Unfortunately the alternating system, which has thus far been adopted, cannot be used with satisfaction for driving motors doing practical work or for charging storage batteries. The continuous current transformer has certainly the advantage in respect to the supply of power and to the charging of storage batteries; but it is a question whether the disadvantage of having to keep it continually in motion will enable it in town lighting to compete with the alternate current transformer. The latter is employed in the Grosvenor Gallery central station in London. Some idea of its importance may be formed from the fact that the Westinghouse Company have already in America over one hundred thousand lamps at work on this system, although it is not yet so much as two years since they adopted it. Notwithstanding that the use of transformers enables a great saving in copper to be effected, more especially where the lamps are scattered, as in suburban districts, yet it is to be remembered that the insulation of underground conductors forms a very important item in their total cost. The installations already at work are all worked with overhead conductors, with the one exception at Eastbourne; so far as the author is aware there are no practical data to establish the general applicability of the transformer system for the lighting of large and thickly populated towns where underground conductors may alone be tolerated. The loss owing to induction will also be vastly greater with underground conductors, however carefully installed. Secondary batteries charged in series by a high tension current and discharged in parallel circuit have been tried experimentally; but their practical application is not known to the author. At the same time, now that transformers are becoming more used, strenuous efforts are being made to introduce this system of secondary batteries; and if it can once be demonstrated to be economical, there can be little doubt that it would have a large field of application. Its great merit is of course the reduction of risk of the light failing. It should be borne in mind by electric light companies that the supply of incandescent lamps is not to be their only source of revenue; but as already pointed out, the supply of current should be of such a nature that it may be employed for as many purposes as possible. By the use of efficient boilers and engines, and properly constructed continuous current dynamos, a central station can be so constructed as to be no nuisance whatever, provided proper precaution be taken in selecting the site. In large towns it will not be necessary to extend the conductors very far before a demand will be met with sufficient for occupying an engine large enough to be economical. Above a certain size the cost of working a steam engine becomes practically constant for any increase in size; so that, instead of working from one large central station over a very large area, it is found better to work from smaller stations over smaller areas. The cost of attendance will thereby be increased to only a small extent, because one man cannot fire more than two boilers; therefore when more boilers are required, it is preferable to work them at another station with another fireman. At Leamington an extensive central station is now at work, and the cost of the undertaking is about £30,000. The Bradford Corporation have recently voted a sum of £15,000 for erecting a central station in their town. Both of these are instances of direct supply, without transformers or secondary batteries.

IV. Electric Metallurgy.

This branch of electrical engineering bids fair to become speedily of the highest interest to engineers. The electro-chemical separation of ores on a commercial scale by the electric furnace has but recently been put to the test, chiefly in obtaining aluminium from corundum, its richest ore. Sir William Siemens first turned his attention to the subject, but his death occurred before he had perfected his invention. It was taken up by Messrs. Cowles, who, with the assistance of Professor Mabery, have devised a furnace, in which by the passage of powerful currents the refractory ore is successfully reduced. The furnace is built of fire brick, and lined with powdered charcoal to withstand the intense heat; it is in the form of a box, 5ft. long, 12in. wide, and 15in. deep. Current is conducted through the walls and into the ore by means of a number of carbon rods, 3in. diam. and from 2ft. to 3ft. long. The positive and negative carbons are introduced from opposite ends, and nearly meet in the centre. The ore, mixed with charcoal and granulated copper, is put in so as completely to surround and cover the carbon. The furnace thus charged is closed with a layer of charcoal and a lid lined with fire brick. Without the protection of some such refractory material as charcoal the intense heat causes the fire bricks to run. When the furnace is ready, the current with an e.m.f. of 50 volts is turned on, and is gradually increased up to some thousands of ampères. In a few minutes the metal is melted around the electrodes; and these are then moved farther apart, until the current passes through the entire charge, and the whole is in a molten condition; the corundum becomes gradually deoxidised, the aluminium combining with the copper, while the oxygen with the carbon escapes as carbonic oxide. About five hours suffices to complete the reduction. Current is supplied by large Brush dynamos—a sketch of which was shown at the meeting. This machine was specially constructed for the work, and is capable of giving out 300,000 watts, or over 400 electrical horse power. Its weight is nearly 10 tons; 5424lb. of copper are wound on the field magnets, while the armature has 825lb. of copper on it. Works already in operation at Lockport, U.S., have a capacity of 6000lb. per day; and the cost of the aluminium bronze so made is expected to be less than 1s. 8d. per lb., while Mr. Cowles anticipates the price being reduced to 8d. per lb. Works have also been started at Stoke-on-Trent, where a 500 h.p. dynamo has been fixed for generating the current; the potential is 60 volts. Another electric furnace has been devised by Dr. Kleiner, of Zurich, in which cryolite, a double fluoride of sodium and aluminium, is similarly treated. When it is remembered that the metal aluminium, in addition to many other good qualities, possesses great strength with only one-third the weight of iron, the importance of obtaining it at a reasonable cost will be readily appreciated. It would undoubtedly cause a great revolution in engineering construction. The process of welding by electricity, introduced by Professor Elihu Thomson, is similarly based upon the passage of a powerful current between two electrodes. In this case the two pieces of metal to be welded form the electrodes; they are brought together into close contact, and as soon as the current is sent through the joint its resistance causes intense heat, until the weld is perfectly completed. The process is almost instantaneous, and the heating occurs only at the joint. Tempered steel can be thus welded without in the least affecting its hardness. Another plan of electric welding has been introduced at St. Petersburg by Dr. Bernardo, in which the heat necessary for fusion is caused by an arc. The current is conducted to the weld by means of a carbon rod, which is connected by a flexible cable with the positive terminal of a dynamo or battery, while the metal to be welded is connected with the negative terminal. The action of the arc set up by the flow of current from the carbon to the metal may be likened to that of the blow pipe flame, except that the heating is more intense and sudden, and is therefore more local. The reducing action brought to bear on the metal keeps it clean and unoxidised.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

At the ordinary meeting of this Society, held on the 9th inst., two papers were read dealing with the subject of alternating current transformers and the distribution of electricity by means of these appliances. The first of these papers we have already reported in our last issue. The second, which occupied the rest of the evening, was by Mr. J. Kenneth D. Mackenzie, and in it the question of distribution was treated from a general point of view, including dynamos, mains, transformers, and certain matters which might best be described as coming under the title of general principles and administration of electric light stations. These two papers were the first on the subject submitted to a scientific society in England. Information in connection with transformers had up till then been carefully withheld by the makers and users of such apparatus—a state of things probably due to the pending litigation on transformers—and the Society of Telegraph Engineers may be congratulated upon having at last broken the spell by including transformers amongst the subjects treated at their meetings. The paper of Mr. Mackenzie was specially valuable, as this gentleman has had considerable practical experience in the working of transformers. The author distinguished between polar and non-polar transformers, the first being of the type of the original Rumkorff induction coil, whilst the latter are developments of the well known Faraday ring. Messrs. Gaulard & Gibbs were the first to take up the subject on a commercial scale, employing polar transformers which had either a movable core or a fixed core provided with a movable gun metal shield, by which means the e.m.f. and the secondary circuit could be adjusted; but these devices were only adopted in their first experimental installations, when it was thought desirable to have means for readily adapting each transformer for the work it had to do. For permanent installations, however, where the conditions of supply could be settled beforehand, Messrs. Gaulard & Gibbs adopted the non-polar type of transformer and introduced a series of improvements, the object of which was (1) reduction of electrical resistance, (2) maximum induction with a minimun weight of materials, (3) perfect symmetry between the primary and secondary circuits, and (4) an equal weight of copper in the two circuits. Referring to the manner of coupling up the transformers in a general system of supply, the author stated that transformers might be worked in various ways. If in series, the lamps fed from each transformer must also be placed in series, and two years ago he had jointly with Mr. Bernstein made some experiments, which, so far as regulation went, were perfectly successful. The primary current was adjusted to the same strength for each experiment, and those lamps which were not required were simply short circuited. He found it possible to short circuit the whole of the secondary without perceptibly increasing the current, and without any danger of overheating. The difficulty he found was not in the transformers, but in the dynamo. He found it almost impossible to maintain the current of the dynamo constant under varying loads, and considered improvements in this direction very desirable. Transformers might be worked in simple parallel arrangement, as is now customary, or they might be worked on the three-wire system, or on the parallel network system, both the primary and secondary mains being all joined in two networks. This is the system employed by Mr. Westinghouse in America. As regards the mains, Mr. Mackenzie is in favour of overhead wires, these being more

Digitized by Google

easily insulated; but he recommends that they should be suspended from bearers, consisting of copper or phosphor bronze cables, by insulated hangers at about every yard. In certain localities the bearers might be steel cables; but in large towns copper or phosphor bronze would be preferable, as not so liable to destruction from atmospheric influences. The bearers should be designed so as to have at least a ten-fold margin of safety against breakage. One of the difficulties he found in connection with bearers was, that on long circuits they became charged with an alternating potential by induction from the mains, and a considerable shock would be felt by touching any of the bearers, although they were insulated from the main. In the early days of the Grosvenor Gallery installation, some difficulty was also experienced from the mains by their inductive effect on the telephone wires, and owing to the number of complaints received from telephone subscribers, the company instructed the author, in conjunction with Dr. Hopkinson, to investigate the subject, and report on the best method to remedy the evil. The installation was then worked on the series system, and the evil was removed by the simple device of running the return main parallel to the outgoing main over the whole of the district. By this means the effect of the current on the telephone wires in one main was neutralised by that in the other main. When the cables are placed underground the author suggests the employment of an earthenware channel, with a cover made as nearly as possible water tight. Within the channel are placed shelves of paraffined wood, on which the conductors rest, and at stated intervals drainage holes are provided for getting rid of water which might find its way into the channel. He does not advocate the use of lead covered cables. In the installation at Aschersleben these cables were used both for the supply and the distributing mains; but it was found that the lead was destroyed by sparks due to a static charge, the cable forming a condenser, and these cables were ultimately abandoned. At the installation in Tours some difficulty was also experienced with underground cables; but since these were laid in earthenware troughs, similar in construction to those suggested by the author, no further difficulties were met with. The author also showed a plan of the port of Spain, in Trinidad, for which he had designed an electric light installation, there being about twenty miles of circuit.

In dynamos for alternating currents considerable improvements have been made during the last few years, the most remarkable of these being the adoption of iron in the core of the armature. In certain cases the author recommends the employment of a low tension dynamo at the generating station, and transforming the current from it by a large transformer into one of high tension, which is sent into the supply mains; but he is opposed to the system of employing dynamos of excessively large dimensions. In this connection he adversely criticised the proposal of one London electric light company to erect dynamos having armatures 42ft. in diameter, and requiring 5000 i.h.p., supplied by quadruple expansion marine type condensing engines. He thinks it far safer to employ a number of dynamos coupled in parallel, the capacity of each dynamo not to exceed about 10 per cent. of the total capacity of the station. There is no difficulty in working alternate current dynamos in parallel, and he has, in fact, done so with Siemens' machines at the Grosvenor Gallery; but he found that the synchronism between the machines was not very stable, and easily disturbed by external influences. With modern machines this difficulty might not prove so great. A diagram of the Kingdon dynamo was exhibited. The peculiarity of this machine is that both the field magnets and the armature form part of the same structure, and that the movable portion of the machine contains iron only, but no wire. Briefly described, the machine which the author and Mr. Kingdon are now building, and which is to absorb 50 h.p., consists of a circular yoke ring, 10ft. in diameter, having a number of short radial magnet cores projecting inwards. Between these revolves the armature wheel, which might conveniently also form at the same time the fly wheel of the engine. Every alternate core is wound with exciting wire, so as to produce north and south poles alternately on the inner end, whilst over the intermediate cores are placed the coils in which the alternating currents are generated. The revolving part consists of a wheel, carrying on its outer circumference a number of soft iron armatures, the width of each being such as to span over the inner ends of two adjacent magnet cores. When the wheel is revolved, these armatures seem to carry north and south lines alternately through the cores on which the armature wire is wound, and by this means alternating currents are generated.

Regarding the placing of transformers, the author is of opinion that to provide a small transformer for each house is only admissible when the number of subscribers is small; but for a general supply and for permanent work the transformer should be kept out of the house, and a sufficient number should be installed throughout the district, so that the maximum distance of any lamp from the nearest transformer should not exceed 120 yards. Great care is to be taken in the wiring of houses, and he deprecated the system of utilising the existing gas fitting for the attachment of lamps. In his own experience, when connected with the Grosvenor Gallery installation, and it was worked on the series system, he has known as many as eight houses plunged into darkness owing to short circuits occurring between the gas fittings and the electric wires in the first and last of these houses. If for reasons of economy it is necessay to use gas brackets, he recommends that their connection with the gas pipes should be interrupted.

THE SOCIETY OF CHEMICAL INDUSTRY.

On Monday, the 6th inst., at a meeting of the above Society, held at Burlington House, Mr. Lewis T. Wright read a paper on "Studies in Coal Distillation." In his experiments he used a Yorkshire coal valued for gas making purposes. An average sample contained 2·26 per cent. of moisture at 100°C., and had the following composition, dried at 100°C.: C 81·92, H 5·39, N 1·28, S 1·97, O 6·88, ash 2·56, total 100·00. In the distillation, temperature observations were made throughout with a Murrie pyrometer with its bulb immersed in the coal; the highest temperature observed was 800°C., and the lowest 600°C. The coal was distilled in a setting of seven double through clay retorts, 18in. by 16in. by 18ft., at various temperatures, requiring from five to eight hours to completely gasify the volatile constituents of the charge of 2cwt. of coal per retort of 9ft. length. The gas yielded varied from 6600 to 12,000 cub. ft. per ton, and the volatile constituents of the coal were gasified at from 50 to 137 cub. ft. per superficial foot of internal retort heating surface per twenty-four hours. The coal was distilled in charges of 2cwt. at temperatures requiring five, six, seven, and eight hours to gasify the volatile constituents of the charge, with the following average results:—

Duration of charge of 2cwt. Hours.	Gas made per foot super. of retort heating surface. Cubic feet.	Specific gravity of tar at 15·5°C.	Fixed carbon in tar. Per cent.
8	50	1·084	8·69
7	62	1·103	11·92
6	91	1·149	15·53
5	133	1·204	24·67

Five samples of tar were drawn off for examination. The specific gravities and yields of gas per ton of coals, on the days when the tar samples were collected, were as follow:—

Specific gravity of tar at 15·5°C.	Coal yielding cubic feet per ton.
1·086	6,600
1·102	7,200
1·140	8,900
1·154	10,162
1·206	11,700

The tars were distilled in a cast iron experimental tar still, capable of dealing with 20 gallons at a charge. The anthracene oils were driven off with steam, and the pitch is not softened, but is hard pitch, not twisting at temperatures under 100°C. The results are here given in weight percentages:—

Specific gravity of tar	1·086	1·102	1·140	1·154	1·206
Ammonia water	1·20	1·03	1·04	1·05	0·383
Crude naphtha	9·17	9·05	3·73	3·45	0·995
Light oil	10·50	7·46	4·47	2·59	0·567
Creosote	26·45	25·83	27·29	27·33	19·440
Anthracene oil	20·32	15·57	18·13	13·77	12·280
Pitch	28·89	36·80	41·80	47·67	64·080

The proportions of the distillates (by volume) coming over at 120°, 140°, and 170° were noted, and the oils volatile up to 140° were re-distilled, and the quantity by volume related to the original crude naphtha coming over up to 100° noted. The results of these re-distillations were given by the author in numerous tables of figures. He also gave the following

Percentage of Pure Anthracene by Weight of Tar.

Specific gravity of tar.	Anthracene. Per cent.
1·086	0·215
1·102	0·267
1·140	0·370
1·154	0·277
1·206	0·232

The creosotes from the 1·206 and 1·154 tar were almost solid with naphthalene. All the other tars yielded perfectly solid creosotes. The oils coming over at 100°C. from the naphthas are at their maximum in the 1·102 sp.gr. tar. The naphthalene makes its appearance prominently in the 1·154 sp. gr. tar. The anthracene is at its maximum in the 1·140 sp. gr. tar. The diminution of the tar acids or phenolic bodies and the middle oils, with increase of temperature, is very marked. Increased temperature tends to destroy chiefly the light oils, intermediating crude naphtha, and creosote.

The author next dealt with the influence of the distillation temperature on the sulphur compounds other than sulphuretted hydrogen occurring in coal gas, saying that gas makers have long understood that such compounds increase as the distillation temperature rises. In his experiments he used gas plant clay retorts. The heat employed may be gathered from the quantity of gas made per ton of coals, stated in cubic feet, corrected to the standards of 60°F. and 30in. bar. saturated with water vapour; the stated sulphur compounds in the washed but otherwise unpurified gas, is given in terms of grains per 100 cub. ft. of purified gas. The author gave his results with the different kinds of coal, and the following with the coal already mentioned:—

	Coal yielding cubic feet per ton.	Grains of sulphur other than sulphuretted hydrogen per 100 cub. ft.	Sulphur other than H_2S per 100 parts by weight of coal.
Average of 8 experiments	11·620	44·17	·033
„ 2 „	10·772	36·93	·025
„ 8 „	9·431	26·75	·016
„ 5 „	8·370	19·16	·010
„ 7 „	6·896	13·91	·006

Lastly, he came to the influence of the distillation temperature on the yield of ammonia from coal. The results were not very determinate, owing to unknown disturbing influences; but at low temperatures the yield is low, at medium temperatures it is at its maximum, and at high temperatures there is again a falling off. The following is a typical case:—

Coal yielding cubic feet per ton.	Ammonia per ton of coal.	Percentage by weight of coal as ammonia.
11,620	7·411	0·331
10,162	7·894	0·352
9,431	7·504	0·335
7,512	6·391	0·285

In this case the maximum of ammonia is with a make of 10·162 cub. ft. of gas per ton of coal.

The Chairman (Mr. Howard) said that they did not know from day to day which one of the products of coal tar distillation would be most in demand for industrial purposes, consequently researches like this would aid gas manufacturers in the future.

Dr. Tidy remarked that in coal distillation if they went much over 10,000 cub. ft. they obtained a large quantity of sulphur; 9500 cub. ft. should be the maximum. Of course gas directors thought that manager to be the best who made most gas, but they would find it to their interest to keep down the make to 9500ft.; when they went on to 10,500ft. they obtained 40 grains of sulphur or upwards, which had to be specially removed. He should like to know the illuminating power connected with Mr. Wright's yield.

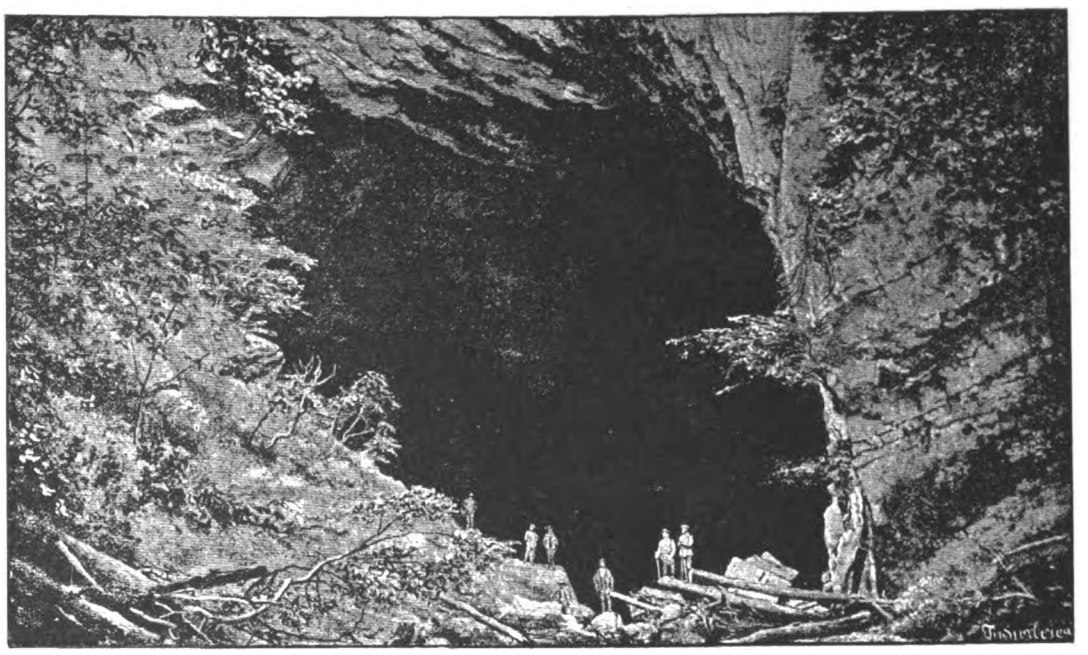
Professor Dewar said that the figures given by Mr. Wright indicated that as they doubled the quantity of gas they squared the quantity of sulphur.

Other speakers stated that there was no difficulty in removing a large quantity of sulphur compounds from gas, and in keeping them down to 14 or 15 grains, also that under some circumstances not yet understood, the sulphur vessel will give off more sulphur than it absorbs, which is a matter deserving investigation.

THE RANGE OF MOLECULAR FORCES.

Professor A. W. Rücker, F.R.S., gave an interesting lecture on molecular dynamics at the meeting of the Chemical Society of London, on Thursday, the 2nd inst., The lecture was illustrated by a series of well devised and novel experiments, upon which great care had been bestowed. The author said that the range of molecular forces has two limits—the one determined by the radius of molecular action, which is not a definite physical or mathematical quantity, and the other by the size of the molecules themselves. In investigations on molecular dynamics we must take into consideration the influence of the medium (if any) in which the molecules are placed, and the problem may be possibly comparable to similar studies on the relations of the bodies in the solar system. The law of the inverse square of the distance is applicable, according to Sir W. Thomson, to bodies very close together, and speculations on the molecular forces are based on this law. It is at present impossible to say when the molecules of any two bodies are directly in contact, and measurements of their size and diameter may include the space around each molecule, into which a third one cannot enter. Some of the earliest experiments which throw any light on these problems were those of Professor Bunsen, on the condensation of gases by solids, in which he determined the amount of carbonic acid, which was condensed on glass plates exposed to that gas. Glass plates also condense water on their surface, and this water is held by molecular forces, so that a temperature of 503° is required to remove the last traces of water from the surface. It is possible to distinguish the water condensation into

Digitized by Google



two kinds, viz.: that which is only temporary and can be readily removed by a current of dry air, and that which is permanent and requires this high temperature before the attraction between the water and glass molecules is overcome. The amount of water which condenses on surfaces has been determined by the balance in the experiments of Warburg and Ihmeri, and they have shown that it is possible to detect an alteration of $\frac{1}{10}$th of a millionth of a millimetre of the thickness of the film. The surface influence varies with its condition, as different results were obtained when the spheres were washed before the experiment. They are of opinion that the water is attracted not by a mere physical force, but that there is a loose chemical combination of the water with the free alkali of the glass. With agate, quartz, and impure opal, the thickness of the condensed film is considerably less, so that the permeability of the substance influences the result. Other experiments in the same direction are those of Lahnman, in which the thickness of threads of mercury were similarly determined, and Müller and Erzbach's experiments point to the same conclusion. Plateau, in his investigations on the thickness of soap bubble films, arrived at the number 118M (M=millionth of a millimetre), for the radius of molecular action between the two surface layers of the film, and the half of this number is very near to the experimental numbers arrived at by Reinold and Rücker in their investigations. Quincke's experiments with silvered plates with water between gave, from a measurement of the amount of silver converted into silver iodide, a value of 50M for the radius of molecular action. Professors Reinold and Rücker's own experiments with soap bubbles have already been alluded to in this journal. There appears to be a sudden change in the surface tension immediately before the film becomes black, and there is a range of unstable thickness due to minimum of surface tension. The surface tension begins to diminish when the thickness of the film is about 100M, and 50M is about the value for the radius of the molecular actions.

Many electrical methods have been devised for attacking the same problem, and of these, the first in the order of time were those of Kohlrausch, in his experiments on the determination of the least thickness of the film of gas required to produce the greatest difference of potential. With oxygen, assuming that the gas was at its ordinary tension, he obtained the value 20M. Helmholtz assumes that the double electrical layer between two dissimilar metals in contact is equal to the distance between the two layers of molecules. In Lippmann's capillary engine the change of surface tension gives values for the molecular radii from 1M to 200M. Wiener's experiments on the interference of light between plates of mica, one of which carries a silver mirror as a reflector, shows that when the thickness is 12M there is still some change. Experiments on the polarisation of light by carbon bisulphide inclosed between two electrified cylinders, show that the beam of polarised light passes when the cylinders are electrified. By means of Clausius' formula, the volume of molecules can be determined from the values of the index of refraction or specific inductive capacity, and Exner, in examining these results, considers that $\frac{1}{3}$th of the volume so obtained consists of matter. Other methods of determining the size of molecules from values obtained for the mean free path in diffusion experiments and determinations of viscosity constants, were alluded to by Professor Rücker. The deviations from Boyle's law also, according to Sir W. Thomson, point to 200M as an approximate value for this number. The following table gives a summary of the chief results which have hitherto been obtained:—

M.		
118.	Superior limit to radius	Plateau&Maxwell
96 to 45.	Beginning of unstable thickness of soap film	Reinold & Rücker.
59.	Superior limit to radius	Plateau.
50.	Value of radius	Quincke.
12.	Lower limit of unstable thickness.	Reinold & Rücker.
12.	Action of light on silver plate	Wiener.
10·5.	Thickness of permanent water film on glass at 23°C.	Bunsen.
4 to 3.	Mean distance between molecules in gases at atmospheric pressure and 0°C.	Meyer.
3 to 1.	Thickness of metal films which polarise platinum	Overbeck.
1 to 0·02.	Thickness of electrical double layer	Overbeck and Lippmann.
0·2.	Smallest appreciable thickness of silver film	Wiener.
0·14 to ·11.	Diameter of hydrogen molecule	Exner and Van der Waals.
·07 to ·02.	Mean distance between molecules in liquid	Thomson.
0·02.	Inferior limit to diameter of gaseous molecules	Thomson.

CHROME STEEL.—The artillery officers at Trubia have succeeded in making excellent chrome steel for tools, and are using it in all drilling machines in that establishment.

THE NATURAL TUNNEL IN VIRGINIA.

THE NATURAL TUNNEL IN VIRGINIA.

WE are indebted to the *Engineering and Mining Journal* of New York for the accompanying illustration and description of this interesting natural tunnel. This remarkable freak of nature is situated amongst the most picturesque portions of the Appalachian range. It serves as an underground passage for a noble river, and the South Atlantic and Ohio Railway Company have taken advantage of the means it provides for overcoming the barriers and obstacles presented by the mountains. Some idea of the gigantic proportions of the tunnel will be conveyed by the illustration, which gives a view of one of its entrances. The great natural bridge which spans the cave has a total length of 930ft., and in some places is more than 150ft. broad. About 200ft. from its southern entrance the tunnel expands into a magnificent circular dome of great height; and the approach to the cave at that extremity is through a semi-circular cañon, the walls of which are over 500ft. high, and overhang the water at their base.

Notes.

NEW FLOATING DOCK AT SYDNEY.

THE first half of an iron floating dock was launched on the 30th November, 1887, at the Atlas Engineering Company's Works, Woolwich, Sydney, New South Wales. This half dock can be used by itself pending the completion of the second half, and is capable of lifting a vessel of 1000 tons. When the two halves are connected, the dock will lift a 2500 ton vessel in less than an hour. An advantage of the dock will be that it can be readily converted into two docks, should two vessels of moderate size require repairing at the same time. The construction of the dock, which will be finally completed in March, 1888, has been under the superintendence of Mr. J. R. Thomson. The launch of the first half was most successful, despite the awkward form of the structure.

COTTON GINS FOR CHINA.

THE United States Consul at Shanghai states that he has been informed that if the Americans would make a hand cotton gin for the Chinese it would meet with a ready sale. As the country where it was made would be immaterial, provided the article proved suitable, we quote the following from the Consul's remarks: "There is a Japanese gin of this kind worked by foot; but it does not pick the seed well, and is but partially adapted to its purpose. The Chinese cotton is coarse and very short staple, and the seed is small. The machinery would have to be adapted to these conditions. An American gin, such as is now used in the South, with a crank to turn by hand, could be easily suited to this work. Anything not operated by manual labour would not be taken up by the Chinese."

HOME AND FOREIGN SHIPBUILDING.

AN interesting return has just been issued by the Norwegian Royal Central Statistical Bureau of the business done in different countries in shipping, from which a few extracts will be interesting to our readers. As, for instance, the following figures in which the year 1880 is compared with 1885, which show a considerable decrease in the relative proportion of the steam tonnage built in the United Kingdom in 1885:—

Statement showing the Net Tonnage built in different European Countries in each of the Years 1880 and 1885, and distinguishing Steam and Sailing Vessels:—

	1880.			1885.	
	Steam.	Sailing.		Steam.	Sailing.
United Kingdom	355,716	59,106	...	205,088	202,362
Denmark	2,416	2,489	...	2,538	2,904
Norway	1,385	23,908	...	5,563	14,180
Sweden	2,575	4,887	...	6,577	3,392
Germany	15,559	9,901	...	9,925	12,316
Holland	909	1,804	...	1,422	7,161
Belgium	—	—	...	1,343	—
France	3,951	9,101	...	5,930	10,591
Italy	89	14,323	...	320	9,533
Austria	3,562	4,205	...	3,454	566
Totals	386,162	129,724	...	242,260	263,005
Percentages of total in each year built in Great Britian	92	46	...	80	76

There is another series of returns which show the tonnage of new ships built in the chief shipbuilding countries of the world during the period 1880-85, distinguishing steam and sailing vessels, a synopsis of which is embodied in the following table:—

	Steamships.		Sailing Ships.		Total.		Percentage of total tonnage.
	No.	Tonnage.	No.	Tonnage.	No.	Tonnage.	
Great Britain	3072	2,633,477	2259	786,966	5,331	3,420,443	79·7
Germany	313	191,672	318	82,292	631	273,964	6·4
Holland	28	24,338	96	19,445	124	43,783	1·0
France	286	143,775	4462*	69,903	4,748	213,678	4·9
Norway	115	25,926	516	102,087	631	128,013	3·0
Sweden	165	32,587	74	16,862	239	49,719	1·2
Italy	33	4,574	1161	79,164	1,194	83,738	2·0
Austria	27	23,857	267	13,957	294	37,814	0·9
Hungary	1	64	25	2,152	26	2,216	0·0
Belgium	5	5,129	—	—	5	5,129	0·0
Denmark	33	20,325	291	13,974	324	34,299	0·8
Totals	4073	3,105,994	9469	1,186,802	13,547	4,292,796	—

* These figures include boats built for the fishing industry.

This on the whole is very satisfactory as regards Great Britain. Another fact which is brought out in these returns is that the United Kingdom builds vessels of larger average tonnage than other countries; the general average of all those built during the above mentioned six years was 761 tons, while the average tonnage for the United Kingdom was 860 tons. The returns for the United States of America are remarkable, and show that thirty years ago these States had one-third of the total tonnage of the world. Now they do not carry much over 12 per cent. of their own ocean carrying trade in American bottoms, and the tonnage of iron ships constructed in the United States has never yet in any one year come up to 40,000 tons, or about the tonnage launched by one of the largest firms on the Clyde or the Tyne.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

3rd February, 1888.

1599. Hallam, W. ..... Looms for macrame lace.
1607. Westley, J. ..... Picker for looms.
1611. Leeming, F. ..... Operating jacquard engines.
1613. Foulis, W. ..... Boilers.
1618. Smith, O. ..... Riveting machines.
1619. Sutcliffe & Longbottom ..... Trap twisting frames.
1621. Benton, C. H. ..... Valve gear.
1625. Cleathero, E. T. ..... Lifts.
1627. Richmond, G. S. ..... Corn grinding mills.
1629. Morris, F. S. ..... Metallic railway sleepers.
1631. Hart, R. A. ..... Machinery for printers.
1632. Cook, W. W. ..... Grinding carding engine flats.
1636. Thomas, J. ..... Sewing machines.
1638. Allchin, H. ..... Weighing machines.
1650. Evans, R. K. ..... Fluid pressure motors.
1652. Standfield, J. ..... Steam ferry boats.
1655. Lake, H. H. ..... Rotary printing machines (*Godchaux & Cie.*).
1660. Blessing, O. ..... Vehicles driven by gas engines.
1661. Dobell & Dobell ..... Sewing machine.
1662. Strachan, T. ..... Kilns for drying grain.
1663. Simpson, W. S. ..... Machine guns.

4th February, 1888.

1668. Wailes, J. W. ..... Shaping heated metal.
1670. Sinnette, F. J. ..... Anchor.
1672. Hawke, F. ..... Bone mills.
1674. Buckley, W. ..... Cylinders for steam engines.
1676. Melling, J. W. ..... Pumping engines.
1678. Mills, E. C. ..... Speed regulators for steam engines.
1686. Webb, F. W. ..... Automatic vacuum brakes.
1687. Knowles & Tatham ..... "Flats" for carding cotton.
1688. Hill, C. G. ..... Sewing machines.
1701. Thomas & Thomas ..... Cross bolt mechanism in drop-down guns.
1705. Crossley, W. J. ..... Compound gas engine.
1706. Crossley, F. W. ..... Compound gas engine.
1709. Ranson & Soderberg ..... Spinning and rope making machinery.
1711. Spratt, C. ..... Speed indicators.
1712. Justice, D. ..... Boiler furnaces.
1716. Brown, W. F. ..... Steam engine indicators.

6th February, 1888.

1720. Foster, T. ..... Wrought fittings for tubes.
1736. Haskins, J. F. ..... Rollers for spinning machinery (*Hoyt*).
1738. Pearce, A. B. ..... Paper machinery.
1741. Cook, W. W. ..... Grinding carding engine flats.
1742. Sage, A. C. ..... Hansom cabs.
1744. Morris, F. S. ..... Buffers.
1756. Brierley, J., & others. Steering apparatus.
1758. Orvis, O. D. ..... Sewing machines.
1759. Haddan, H. J. ..... Expansion regulating gear (*Rademacher & Voss*).
1763. Stanley, R. ..... Tunnelling machines.
1764. Stanley, R. ..... Kilns for burning bricks.
1767. Brogden, G. W. H. ..... Manufacture of pulleys.
1769. Howard, A. H. ..... Rowing machines.
1773. Heggie & Raven ..... Cutting glass tubes.
1776. Poyser, J. ..... Sewing machines.
1778. Kreiss, E. ..... Screw conveyors.
1780. Butler, E. ..... Hydrocarbon motors.

7th February, 1888.

1787. Tugwell, T. ..... Sewing machines.
1788. Sutherland, W. S. ..... Welding plates.
1789. Potter, R. ..... Marine speed register.
1793. Johnston, D. ..... Screw propeller blades.
1795. Richardson, R. ..... Steering gear.
1797. Allred, R. ..... Hoists.
1799. Richardson, A. S. ..... Sewing machinery.
1802. Burdon, C. ..... Breaking up macadam roads.
1804. Selous, W. J. ..... Printing wall paper.
1806. Lane, C. ..... Air guns.
1810. Thomas, F. T. ..... Rotary engine.
1811. Hill, J., & others ..... Grinding carding engine flats.
1812. Kay, S. ..... Automatic railway brakes.
1814. Anderson, F. ..... Mules.
1817. Taylor, G. ..... Shipping coal.
1820. Hopkinson, J. G. ..... Manufacture of boots.
1822. Bondkowski, J. ..... Pumping machinery.
1823. Vyrazil, F. ..... Evaporating apparatus.
1824. Boult, A. J. ..... Steam generators (*Stehlik*).
1825. Childers & Milne ..... Signalling apparatus for railways.
1829. Rookes, G. C. ..... Paper making machinery.
1830-1. Imray, O. ..... Embroidering machines (*Smith*).
1832. Worms, J. ..... Aërial machine.
1834. Bramall, J. ..... Steering boats.
1837. Lake, H. H. ..... Riveting machines (*Saxe*).
1838. Lake, H. H. ..... Ships' masts (*Mansfield*).
1840. Edwards, E. ..... Threshing machines (*Cuhel and Cuhel*).
1841. Lieb, C. A. ..... Automatic grain scales.
1842. Wise & White ..... Machine for trimming brushes.

8th February, 1888.

1852. White, J. P. ..... Submerged water wheel.
1854. Greenwood & Skipworth ..... Weighing machines.
1855. Greenwood & Rigby ..... Windmill.
1858. McConnell, T. ..... Breech loading fire arms.
1867. Howell, S. E. ..... Manufacture of tubes for boilers.
1871. Beveridge, J. ..... Furnaces.
1877. Macpherson, A. ..... Launching ships' boats.
1879. Higham, I. ..... Propelling boats.
1881. Arnold-Forster, H. O. Defending ships against torpedoes.
1894. Farrell, M. D. ..... Machines for corking bottles.
1895. Watson, J. de L. ..... Starters for tram cars (*Watkins*).
1897. McIntyre & McIntyre. Forced blast for furnaces.
1900. Throop, J. W. ..... Straw cutters (*Kendrick*).
1909. Langham, J. ..... Knitting machines.
1912. Barnier, J. ..... An improved motor.
1916. Schonheyder, W. A. G. Caloric engines.
1920. Ruf & Kumpfmiller ..... Lathes.
1924. Warden, G. C. ..... Roofs.
1925. Drake & Muirhead ..... Valves used with pumps.
1930. Woodhouse & Taylor ..... Embossing presses.
1931. Ewing, W. J. ..... Water brakes.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Compound Steam Engines.—*A. V. Newton, London.* (*J. Ericsson, New York.*)—The construction of compound engines, which is the subject of this invention, will be understood by reference to the accompanying diagram, which represents a longitudinal section of the important parts of the cylinders. A A¹ are the two cylinders, of which A works with high pressure steam, and A¹ with the exhaust steam from A. The pistons B B¹ are mounted on the same piston rod C, which passes through the two stuffing boxes D and E. The ratio of the diameters of the pistons is as 1 : 3. The valve gear of the small cylinder is so arranged that the cut-off shall take place at one quarter of the stroke, and the total expansion of the steam on the two cylinders will therefore be to thirty-six times its original volume. The condenser is shown at F. The cylinder A is fitted with two valves H I at one end, and with two valves H¹ I¹ at the other, the valves H H¹ being for the entry of steam, and the

valves I I¹ being for the eduction of the exhaust steam from the cylinder A to the cylinder A¹. The ducts J J¹ serve to introduce this exhaust steam to the expansion chambers of the second cylinder, and K K¹ are the final exhaust valves, which allow the steam to escape to the condenser F. The valve gear is not shown on the diagram, and it is allowable to use any convenient form which will operate the valves in the necessary manner. The claim which is made is for a double acting two-cylinder compound engine, organised substantially as described, whereby steam may be used at the highest practicable initial pressure, and with a high rate of expansion in the smaller cylinder; and afterwards may be expanded in the low pressure cylinder to the lowest tension which would be economical.—No. 15795. November 17th, 1887. 6*d*.

Hydraulic Lifts.—*C. F. Archer, London.*—The inventor makes use of three hydraulic cylinders—the pressure cylinder, the accumulator cylinder, and the lift cylinder. The power in the pressure cylinder is exerted by means of its ram on a chain which passes round a fusee. The shaft which carries the fusee also has fixed to it another similar mechanism, and the chains wound thereon cause the accumulator ram of the second cylinder to descend. This cylinder and the lift cylinder are connected by means of a pipe, which allows the water to flow backwards and forwards during the various operations without any appreciable loss of volume. The lift is supported, as usual,

Digitized by Google

on the top of the ram of the lift cylinder. The inventor does not confine himself to the fusee for the purpose of supplying a compensating mechanism, and, in some cases, makes use of a rack and an eccentric pinion. The claims are (1) for the combination of the three cylinders as described, and (2) for the fusee or eccentric mechanism between the pressure and compensating cylinders.—No. 3634. March 10th, 1887. 8*d*.

Fluid Meters or Motors.—*H. Frost, Manchester.*—This invention relates to improvements in the construction of the apparatus described in the Specification of Patent No. 2720 of 1883, granted to the same patentee. The appended diagrams represent vertical sections taken at right angles to one another. The outer casing is composed of three pieces A A^1 A^2. B designates the measuring cylinder, B^1 the passages leading from the upper part of the meter to the bottom part of the measuring cylinder, G^1 the piston, N N^1 collars on the piston rod, J the inlet, and K the discharge pipe. The present improvements consist of casting in one piece the supplementary cylinders D D^1 with their ports and passages. The port E communicates by a passage with the cylinder D, and the port E^1 communicates

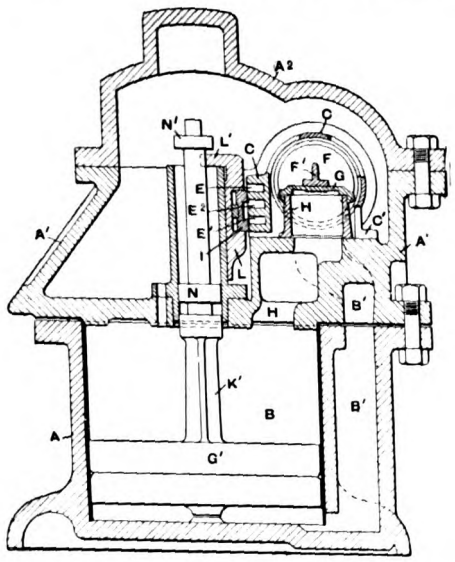

Fig. 1.

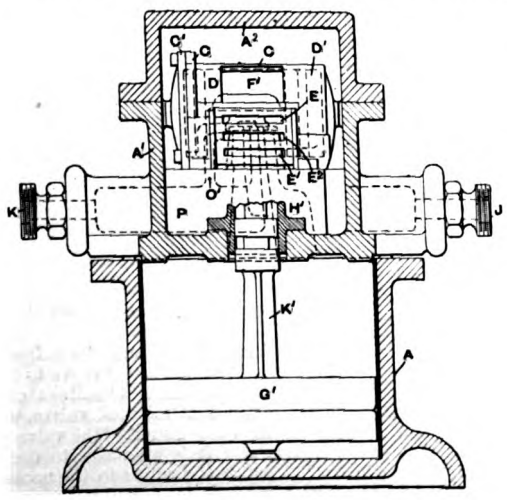
by another passage with the cylinder D^1, while E^2 communicates by a passage O^1 in the block C and a passage P in the casing A^1 with the discharge pipe K. The piston rod F^2 is formed to fit over a valve cover G, which controls the three ports in the main valve block H. The three ports respectively communicate with the bottom of the cylinder B, through the passage B^1, with the top of the cylinder B by the passage H^1, and with the pipe K through the passage P. When the fluid under pressure is admitted to the middle port A^1 of the meter through the inlet J, and when the piston G^1 is at the bottom of B, the fluid flows through the first port in H down B^1, causing the piston G^1 to rise. Near the end of the upstroke the collar N^1 catches the projection L^1 on the valve mover L, and moves I upwards, and so uncovers the port E^1. The liquid then flows through E^1 into the cylinder D^1, and moving the valve cover G so as to uncover the second port in H. The piston F is forced inwards and expels the fluid from D through the port E into the discharge pipe K. As the main piston G^1 has attained the top of



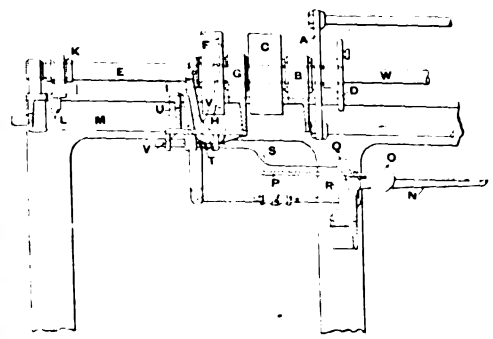


Fig. 2.

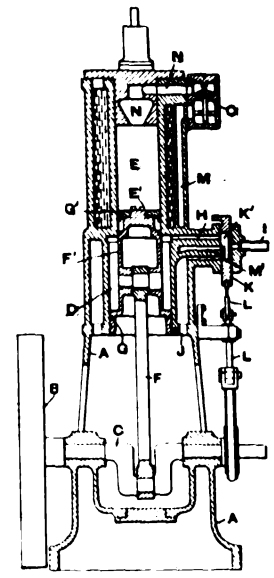
its stroke, the fluid flows through the second port in H into the top of the measuring cylinder B and forces down G^1. The fluid on the under side of G^1 is thus expelled up B^1 through the first port in H, under the recessed valve cover G, down through the central port in H, through P, and out through K. As the piston rod K^1 approaches the end of its downward stroke the collar N^1 catches L^1 and moves the valve cover I downwards, and uncovers the port E, thus allowing the fluid to flow through E into D, so that the first port in H is uncovered; and the fluid in D^1 is expelled through E^1 under I, down through E^2 O^1 P, and out at K. The stroke of K^1 is then reversed once more. When used as a meter the apparatus is provided with an indicator, and when as a motor the piston rod K^1 is lengthened and attached to a crank on the outside of the casing. The inventor makes two claims.—No. 2578. February 15th, 1887. 8*d*.

Propulsion of Ships.—*W. MacGowan, Ardrossan.*—The machinery here described is adapted more particularly for the propulsion of sailing ships during calms, and for supplying motive power to a steamer whose main engines have broken down. This object is gained without the machinery proving a hindrance when not in use. The propeller is formed of two nearly flat blades mounted on spindles, which are placed exactly opposite each other. The blades are made nearly circular at the inner propelling part next to their stems, and at the outer part of an unsymmetrical pointed shape, so that when the discs are rotated the water first meets the forward lower part and passes across it in curved lines towards the aft and outer part of the blade. The blades are also provided with a swivelling motion on the arms, in order that they may be set in a line with the keel while out of use. The propeller shaft is made hollow to admit a rod, which by means of suitable mechanism enables an operator in the engine room to adjust the blades to any desired angle. The inventor makes six claims for the general construction of the propelling mechanism, and for the parts as described.—No. 2761. February 22nd, 1887. 8*d*.

Rope and Belt Shipping Device.—*R. Hornsteiner, Prague, Austria.*—This invention relates to a construction of rope pulleys, which is intended to facilitate the shipping of the rope. The flange on the rim of the fast pulley, bordering on the loose pulley, is made to project further from the centre of the shaft than the outside rim, and the flange on the rim of the loose pulley next to this projecting flange is made correspondingly small. In the periphery of the projecting rim of the fast pulley are several depressions where the projecting rim of the pulley is as small as the other rim. The shipping is effected by means of guides, which press the rope against the projecting rim, and when, in the revolution of the pulley, the approaching rope comes in contact with the depressions in the rim, there is no lateral resistance to the rope, which is accordingly shipped on to the other pulley. The inventor claims the method of shipping by cutting down this projecting flange at certain parts of its periphery.—No. 16286. November 26th, 1887. 6*d*.



Spinning Machinery.—*A. T. Lawson, Leeds.*—This invention relates to machinery for spinning yarns from flax, hemp, &c., where a drag on the bobbin is required. The apparatus designed for this object is represented in side elevation in the accompanying figure. The flier A is fixed to a hollow axis, which turns in bearings in a block B, and a band pulley or gear wheel C is also fixed to the same axis for the purpose of driving the same. D is a bobbin plate on a traverse tube E, which passes through the hollow axis of the flier, and is supported by the spindle W. A friction pulley F is mounted on a hollow axis, which is carried in bearings in the block G. It is driven by a band, which travels at a speed somewhat less than that of the band which drives the flier. The tube E passes through a loose friction disc H, whose boss has a feather projecting inwards and entering a key way cut lengthwise in the traverse tube. The disc is pressed against F by a lever I, a disc of leather being interposed between the two surfaces. The axis of the lever I is carried by a bracket V. The

end of the traverse tube is coupled to the slide K, and the tooth L projects downwards from the slide and engages with the traverse screw M, in order that the traverse tube may be moved to and fro by this screw. The lever I is coupled at its lower end by a link to the short vertical arm of the lever N. The weight O is mounted on the longer end of this lever, and is capable of sliding along it; P is a toothed rack; and Q a pawl which is carried by an arm R turning freely round the axis of the lever N. The sliding rod S is coupled to R, and is acted on by a spring T, which draws the arm backward from the weight. U is a finger projecting from S. The traverse slide strikes against this finger in its movements to and fro, and thereby shifts the rod S endwise, and causes the pawl to shift the rack and weight along the horizontal arm of N. In this way, as the yarn accumulates on the bobbin, the drag or friction holding between the friction disc and its driving pulley is increased so as to give greater driving power. The difference between the number of revolutions of the bobbin and flier is thus gradually diminished. The inventor makes three claims for the combination of the uniformly rotating flier and the mechanism for gradually increasing the hold between the friction surfaces, and for the arrangement of machinery described.—No. 16725. December 20th, 1886. 8*d*.

Separator.—*A. F. Craig, Paisley, A. Neilson, Inkermann, Renfrew, and J. Snodgrass, Midlothian.*—The object of this invention is to obtain a continuous separation of oils of different specific gravities in the refining process of mineral oils. The apparatus is worked on the centrifugal principle, and is an adaptation of that described in the specification of Patent No. 3749 of 1886, granted to the same patentees. A rotating vessel is placed with its axis horizontal, and is formed of cast iron discs connected with a cylindrical or slightly tapering shell of wrought iron. The shell is strengthened with ribs, which also assist the rotation of the liquid, and the discs are formed with tubular bosses projecting outwards from their centre. These bosses act as bearings for the support of the machine in its journals. The liquid is introduced through a pipe in one of the tubular bosses. On the inner side of the disc an inlet pipe is made with two or more radial branches extending nearly to the circumference, and the ends of these branch pipes are curved in the direction of rotation, so as to deliver the liquid quietly. The lighter oil is led off through a stationary pipe placed near the highest part of the annular layer of lighter liquid, and at the opposite end to that of the entrance of the oil. This oil pipe is held stationary, and the oil rises up the external part of it in consequence of the energy of rotation acquired in the vessel. This elevation of the oil facilitates its conveyance to a tank for accumulation and storage. The heavy portions of the oil pass through syphon passages, or may be delivered from a channel in the disc by means of stationary pipe. A valve is provided for emptying the vessel, as it cannot be conveniently started except when empty. The various parts of the machine are open to more or less modification. The inventors make three claims.—No. 3617. March 10th, 1887. 8*d*.

Gas Engines.—*H. Williams, Stockport.*—In this arrangement of parts, the power cylinders and the charging cylinders are combined and operated by one piston. The cylinder of the engine is bored out with two different diameters, the gas being drawn in by the larger part and compressed and ignited in the smaller end. A new charge is introduced at the instant when the power piston has almost reached the limit of its outward stroke, and at the moment when the products of the combustion of the previous explosive charge are being driven out through the exhaust ports in the power cylinder. The arrangements according to this invention are represented in the accompanying diagram. When the engine is first started, a mixed charge of gas from the pipe 1 and air from the pipe J is drawn through the

passage K^1 and H into the larger cylinder D on the outward stroke of the piston G. The position of the slide valve K is then reversed so as to close the pipe I and the air passage J, and by means of the passage K^1 places H in communication with the reservoir M. As the piston moves inward, the mixed charge is driven from the cylinder D and compressed into the reservoir M, where it is held between the valves O and K until the pistons G G^1 have again nearly reached the limits of their outward stroke. At this moment the pressure on the contents of E will be reduced sufficiently to allow the mixture in M to raise the valve O and enter the cylinder E. The pistons then return on their inward stroke, compressing the mixture into the combustion chamber E, while the charging piston G compresses into M the mixed charge drawn into the cylinder D on the previous outstroke. The instant the pistons reach the limit of their inward stroke, the charge is exploded in the combustion chamber; and on the succeeding outward stroke the piston G draws into the cylinder D through the passage H a fresh charge of mixed gases. When the pistons have nearly performed their outward stroke, the tension on the products of combustion will be reduced sufficiently to permit the new charge to rush from M through O into the cylinder E, thereby sweeping out the products of combustion through E^1. The cycle of operations is then subsequently repeated. The inventor makes three claims for the combination of parts described and shown in the diagram.—No. 16029. November 22nd, 1887. 8*d*.

Joints for Corrugated Metal.—*W. P. Thompson, Liverpool.* (*H. C. Hodges, Detroit, U.S.A.*)—It is the purpose of this invention to provide an improved method of jointing semi-tubular rods which cross at any angle, and for fixing a corrugated roof to the supporting beams. The usual bolts occasion too much strain in the metal when they are screwed up. The inventor employs pieces of metal, which are shaped in convenient forms, for filling the hollows of the corrugations where the metal rods cross each other. The bolts are placed through these filling pieces, and when the bolts are screwed up, the filling pieces take most of the strain on themselves. These pieces are generally to be made of malleable iron. The inventor makes four claims for these improvements.—No. 16426. November 29th, 1887. 8*d*.

Spinning Machines.—*E. Maertens, Providence, U.S.A.*—This invention is designed for the purpose of providing a means of changing ordinary spinning machines into multiple drive and tension machines. The spindles are arranged in sets on each side of the machine, and each set comprises a series of spindles; the band is carried over and in contact with the drum in crossing from one series of spindles to the other at one end of the set, and under and in contact with the drum in passing from series to series at the other end of the set. A tension band is employed, and is applied at such a point that it will not interfere with the driving contact between the drum and the bands where the latter crosses the former. In connection with the band the inventor uses a direct acting tension pulley, which is carried by

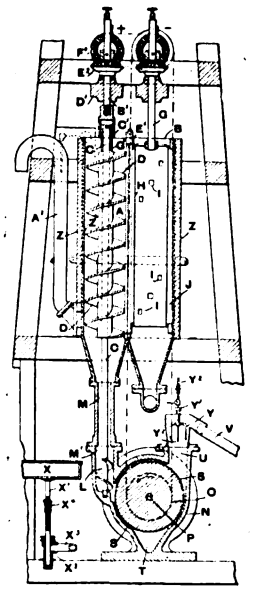
Digitized by Google

a weight compensating lever, and he dispenses with the usual carrying pulleys. The pulley which receives the tension loop of the band has a shaft which is adapted to a recess in a block of wood. This bearing block is adapted to the recessed outer end of one arm of the tension lever, the other arm of which is provided with a suitable adjustable weight. The lever is hung to a transverse shaft, and the arm of the lever is made in two parts connected by a bolt at right angles to the shaft, so that the arm is free to swing in a plane at right angles to that in which the lever moves. The tension pulley is thereby enabled to accommodate itself to any angle assumed by the tension hoop of the driving band. The hub of the lever is notched, so that it can be easily dropped on to the pivot rod; it is also recessed for the reception of a ring secured to the pivot rod, and a lug projecting into a slot in the hub serves to limit the swinging motion of the tension lever. The ring is provided with a set screw, whereby it is secured upon the pivot rod in any desired position which the variations in the limit of the movement of the tension lever may demand. Various other forms of lever may be used, but the one above described is preferred. The inventor makes eight claims.—No. 6746. May 7th, 1887. 8*d*.

Boiler Flues.—*T. Oldham, Stockport.*—This invention involves a new method of forming boiler flues, with the object of strengthening them sufficiently to prevent their collapse when subjected to external pressure. The tubes are to be made up of rings of short length. The ends of the rings are flanged, and the flanges are welded together. The flange of each ring should be made of slightly greater diameter than that of the next one, in order that they shall fit easily one within the other. These flues will be free from joint. The inventor makes three claims for this invention.—No. 3944. March 16th, 1887. 8*d*.

ELECTRICITY.

Electrical Transformers.—*G. Kapp, W. H. Snell, & J. M. V. Kent, London.*—The object of this invention is to produce a simple and efficient type of apparatus adapted for self regulation when used either in parallel circuit or in series. According to one arrangement the core is formed of a number of U or ⊔ shaped plates, which may be economically stamped out of thin hoop or sheet iron, so that when any number are placed face to face a trough is formed. The plates are insulated, and the coils of insulated wire are placed upon their upright sides or horizontal base. Two such troughs may be placed side by side, forming a double trough, and separated by distance pieces for ventilation; the coils may be then placed over the adjacent sides of the troughs. The primary and secondary coils are separately wound and placed side by side so as to be readily detachable. A cover for the trough is formed of rectangular plates, which are insulated from each other and wound with detachable coils. When placed in series the self induction of the secondary circuit may be reduced by dividing the iron core into sections and providing each one of the sections with a secondary coil, each connected with a distinct circuit. To increase the surfaces of contact of the cover and trough, the cover and upper extremities of the sides of the trough are bevelled obliquely to fit each other. The sides of the trough may be tapered, and by this means the magnetic effect of the apparatus may be varied by varying the depth to which the cover is inserted. The efficiency may thus be regulated by hand or automatically, or the movement of the cover may be utilised for the actuation of any regulating device. In the latter case the apparatus may be used either with alternating or with continuous currents. The inventors make four claims.—No. 1904. February 7th, 1887. 8*d*.

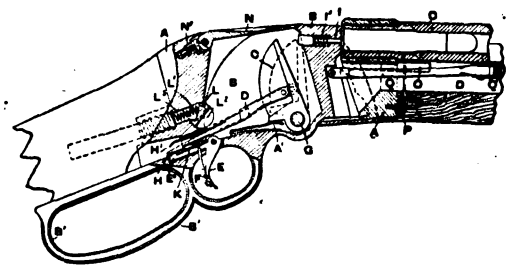


CHEMISTRY.

Paradiamidodiphenyl Sulphonic Acid.—*T. Carnelley, Dundee.*—The inventor produces the acid by treating paradiamidodiphenyl with sulphuric acid, the proportion of the chemicals being one part of diamidodiphenyl to four of the acid. This mixture is heated to the temperature of 130°C. for half an hour. The product is allowed to cool, and is afterwards thrown into cold water. The acid is then ready for use in the manufacture of dyestuffs. The inventor makes one claim for this process.—No. 3890. March 19th, 1886. 4*d*.

Clarification of Sugar.—*A. Brin, London, and L. Q. Brin, Paris.*—The saccharíferous matter is placed in a wooden vessel after having been reduced to a liquid state. The vessel is fitted in its interior with centrifugal beaters or stirrers, and with a steam coil through which steam is introduced for the purpose of heating the contents. The clarification is effected by passing through the liquid a mixture of ozone and electrified chlorine. A small quantity of alumina is added to the solution, and after the action of the nascent oxygen and chlorine the addition of carbonate of soda insures the precipitation of any matters detrimental to the sugar. After the clarification has been effected in this manner another stream of ozone is passed through, in order to deodorise the resulting product. One advantage of this method is that it avoids the possibility of the invertion of the sugar. The inventors make five claims for the application of ozone and electrified chlorine for the purpose described.—No. 2297. February 14th, 1887. 6*d*.

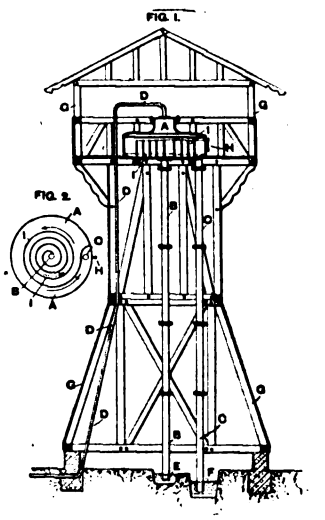
Basic Sulphocyanides of Aluminum, Iron, and Chromium.—*J. Hauff, Stuttgart.*—These chemicals are intended for use in dyeing and printing processes in place of the neutral sulphocyanides which have hitherto been employed. They do not decompose so readily when evaporated in a water bath, and they are otherwise more steady in their behaviour. The aluminium salt forms a good mordant for dyeing. The method of production is by warming the neutral sulphocyanide or sulphocyanic acid with the freshly precipitated hydrated oxide of the metal. The inventor claims the production of these salts in the manner and for the purpose described.—No. 5109. April 6th, 1887. 4*d*.



Separating Gold from its Ores.—*G. J. Atkins, London.*—The apparatus illustrated in the accompanying drawing has been designed for separating the gold from its ores by an electrolysing and amalgamating process. The ore is introduced by a hopper into the top of the cylinder A. The chambers A and B contain an electrolysing solution; and the shafts B^1 and G cause the screw D and the drum H to rotate within the two chambers respectively. The current of electricity is led through the solution from the two poles on the shafts B^1 and G. The chambers are separated by a porous plate, which allows the free passage of the electrolyte, but not of the gangue. The screw D turns in such way as to retard the fall of the ore. The part of the ore dissolved by the electrolyte is deposited on the drum H, whence it is swept off by the rubbers J. The amalgamating apparatus is seen lower in the figure. The gangue is fed into the cylinder N, in which revolves the drum O, with a grooved periphery S. Mercury fills up the space between the drum and the cylinder, and unites with the gangue during its

passage through N. The resulting amalgam is led off through the pipe V. In order to regulate the rate of passage of the gangue through the cylinder, an apparatus is designed for lowering or raising the level of the mercury in the cylinder, and thus altering the pressure of the mercury on the gangue. This apparatus consists of a reservoir of mercury X, which may be raised or lowered by the screw X^4; and the pipe X^3 communicates from this reservoir with the bottom of the cylinder N. The mechanism Y helps to abstract the amalgam from the tube V, if it is too thick and pasty to effect its own exit. The inventor makes ten claims for these combinations.—No. 12295. September 28th, 1887. 8*d*.

MISCELLANEOUS.



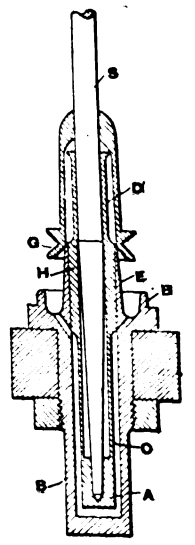
Breech Loading Fire Arm.—*A. Lindner, Berlin.*—The object of this invention is to overcome certain disadvantages incident on the use of rotary block systems, viz., that the cartridge must be driven home into the cartridge chamber before the block can be closed, and that should the cartridge become deformed, it can only be removed from the chamber by means of the ramrod. The arrangements of parts designed to overcome these difficulties will be seen by reference to the accompanying diagram, which represents a vertical section of the breech action. The breech block is closed, and the parts are in the position which they occupy when ready for firing, and the dotted lines show the position they assume afterwards. The breech block B is hollowed out to receive the main spring A^1, the hammer C, the arm D, the trigger E, and the fulcrum G. The part of B which closes on to the cartridge is bored out to

receive the firing pin I. The arm D is at one end fastened to the hammer C, and glides in a groove in the curved surface of B, whilst its extreme rear end moves in a cavity in the butt of the gun, where it is provided with a flat spring H^1 and a hook H pressing on the cavity K. These parts are for holding the mechanism in cocked position. To prevent the block being opened by the force of discharge, a rotary bolt L with recesses L^1 L^2 is arranged on the breech receiver A, and is kept under the influence of the spring L^3. A thumb lever is fixed to the end of this bolt. The flap N is operated on by a spring N^1, so that the loaded cartridge can be fed into the chamber. The extractor consists of a rod O, with the upper end recessed to grip the flange of the cartridge, and with a groove at its forward end. One prong of the fork P gears with this groove. The auxiliary rod Q is pivoted to the breech block, and carries a cylindrical casing Q^1. After the weapon has been fired off the thumb piece on L is to be depressed, and the lever B^1 pushed downwards, so that the block B is compelled to turn on its axis G. During this movement the arm D is pushed to the rear of the cavity, and the flap N is depressed by N^1, so that it remains in contact with B. The rod Q is drawn to the rear, so that a knob on its forward end comes in contact with the end of P. By means of some details of this mechanism, the cartridge is extracted and ejected over the shoulder of the shooter. A loaded cartridge is now introduced, and the block closed. The arm D is depressed, and is caught by K, thus hindering the hammer from moving with the block. As soon as the block is fully closed, the spring L^3 will force forward the bolt to the thumb piece on L, so that L enters a depression in the bolt. The parts are now at full cock, and the rear end of D is above E^1. As soon as E is pressed to the rear, the arm D will be freed from gear with K, and A^1 will propel the hammer against the firing pin I, thus driving it against the cap. The inventor makes six claims for this arrangement of parts.—No. 15043. November 4th, 1887. 8*d*.

Spinning Spindles.—*A. McCulloch, A. Carrie, & D. Ogilvie, Dundee.*—In carrying out this invention the fibrous materials are wound in the form of inverted cops on vertical spindles. This winding takes place on the lower part of the spindles, and the cop is gradually pushed up as it is formed. The twisted material passes on to the spindle over the upper edge of a hollow inverted cone which rotates with the spindle. This cone is carried by a rail to which the up and down traverse motion is imparted. The cone is shaped to fit the conical surface of the cop, and serves to push the cop gradually up the spindle. In one modification of this invention there is a follower or ring placed outside the cone, rotating in the same direction as the spindle. The rotation of the ring is caused to be at a slower rate than that of the spindle by the application of a weighted drag cord; and one or more wire guides are fixed to the ring. The yarn descends and proceeds to the guide wires, and thence over the rounded edge of the cone to the spindle. The rotation of the ring is caused by the action of the spindle through the thread. In another modification a fixed ring with a traveller is employed instead of the rotating ring. The inventors make six claims for the combination of rotating spindle, rotating cone with traverse motion, and rotating follower, together with the modifications.—No. 3635. March 10th, 1887. 8*d*.

Extracting Gases from Liquids.—*E. Luhmann, Niedermendig, Germany, and C. G. Rommenhöller, Rotterdam.*—The apparatus designed by the inventors is shown in elevation in Fig. 1 of the accompanying diagrams. The frame work G, which is preferably about 20ft. or 30ft. high, supports a vacuum pan A, and the pipes B C D. The pipes B and C are connected with the supplies of water E and F, while D communicates with an air pump. In the vacuum pan is a spiral partition I, which is shown in plan in Fig. 2. The object of this division is to increase the distance between the openings of the pipes B and C. When the apparatus is in action, the water from which the gases are to be extracted

is drawn up the pipe B into the pan A, and during its travel in the direction of the arrows is exposed to the suction of the air pump through D. The pipe C acts as an exit for the water. This direction of circulation is insured by the fact that the level of the water in the reservoir E is higher than that of the water in F. This apparatus may be employed specially for the extraction of carbonic acid from water, and also may be employed in the sugar mills for obtaining the syrup in a more consistent state by extracting the steam from it. The inventors make two claims.—No. 14775. October 31st, 1887. 6*d*.



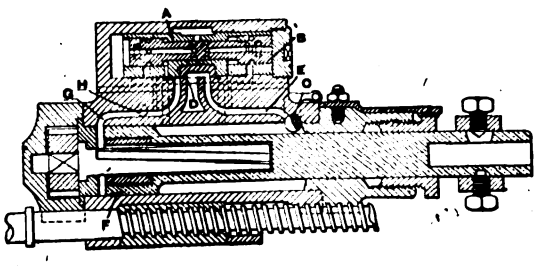
Elastic Fabrics.—*W. Lapworth, Hopedale, Massachusetts.*—The object of this invention is to produce an elastic fabric having a twill on both face and back, the material showing on both twills being composed of the weft instead of the warp, as heretofore. By causing the weft to constitute the visible part of the twills, it is possible to use cheaper threads for the invisible warp. The weft is introduced preferably by one shuttle; but if two shuttles are used, with different coloured weft threads, the fabric may be manufactured with different colours on the face and back. The fabric is woven in a six-time motion, the warp threads are up three and down three, and the fibrous warps are carried by the heddles of three harness frames, while the rubber, or cord warp, is carried by the heddles of one harness frame. The inventor makes one claim for this improvement.—No. 3153. March 1st, 1887. 6*d*.

Alignment of Shaft Bearings.—*E. Stinton, Ipswich.*—One form of the apparatus designed by the inventor consists of a tube fitted with several pairs of different sized collars, by means of which the tube may be mounted in different sized bearings. At one end of the tube are cross wires, and at the other end is an eye piece. In another form of apparatus, the adjusting collars are dispensed with, and in their place are four bars which are parallel to the tube and jointed to it by links. By either of these instruments the true alignment of shaft bearings may be obtained with precision. The inventor makes one claim for apparatus designed for this end.—No. 5472. April 15th, 1887. 6*d*.

Digitized by Google

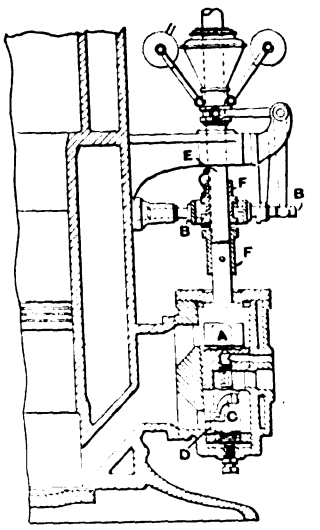
Bobbins for Winding Yarns.—*T. Brown, Sheffield, and W. Pickstone, Radcliffe, Lancashire.*—The object for which the inventors designed these bobbins is to secure both strength and lightness. A sheet of steel is bent into the form of a tube, and to each end of the tube a steel disc or ferrule is fixed. These discs constitute the flanges of the bobbin, and a number of holes are punched in them in order to increase their lightness without diminishing their strength. When the beams or bobbins require to have a longitudinal slot along their length, the sheet out of which the bobbin is constructed is made, before it is bent, with its two end parts at the edge projecting beyond its middle, so that when the sheet is bent until the two edges meet at the ends there is left an opening between the edges, and the flanges are fixed on that part of the tube where the two edges meet. In some cases the sheet may be bent not quite into the shape of the tube, thus leaving a slot along the whole length. The discs in those cases are made with feathers projecting into the slot, which are secured to the tube by T headed bolts. The inventors have designed several alterations in the details of this mechanism, and what they claim is: The construction of bobbins or beams for winding yarns and textures, with their cylindrical parts made of steel plate bent round to tubular form, and provided at the ends with steel flanges, ruffles, stiffening rings, and struts of various sections and sizes as described.—No. 3282. March 3rd, 1887. 8*d*.

Spindles and Bolsters.—*H. H. Lake, London.* (*C. H. Chapman, Groton, Massachusetts, U.S.A.*)—Spindles having a sleeve whirl cannot be easily held in a vertical position while running at high speeds. The inventor proposes a construction for the spindle and bolster which will overcome this defect, and the accompanying figure represents a section of the designed apparatus. The step bearing A is suspended within the bolster case B by means of the thin connecting sleeve C. The walls of this sleeve are made of such a thickness that they are elastic and



will spring sufficiently to permit the step bearing to yield to the lateral pressure of the foot of the spindle S. The support C also presents sufficient resistance to the motion of the spindle to prevent any gyration. The spindle S is tapered upward to a point above the bolster neck E, so that the entire bolster bearing surface shall be above the rigid lateral support of the neck. The bearing D is thus much less dead to the pressure of the spindle, and is also enabled to yield slightly by its own elasticity and conform to the movements of the step below. The bolster bearing D is fixed to the bolster case by means of its lower end H, which is driven firmly into the neck E. The inventor also specifies a modification designed to attain the same end, and he makes six claims for the whole invention.—No. 2376. February 15th, 1887. 8*d*.

Briquettes of Waste Fuel.—*L. A. Brode, Glasgow.*—The coal waste is ground to a powder and placed in a mixing machine. There is then added a sufficient quantity of a solution produced by the combination of boiling water with silicate of soda and ground rice. The whole, being mixed, produces a thick, clayey substance, which is then moulded into bricks and dried. The inventor makes one claim for this process.—No. 2092. February 10th, 1887. 4*d*.



GERMAN PATENT ABSTRACTS.

Rock Drill.—*M. Kuzel, Penzberg.*—This invention relates to improvements in the valve gear regulation and locking apparatus of rock drills worked by compressed air. The valve gear consists

of an ordinary slide valve D, actuated by the pistons A and B, and so arranged that B slides in A, while A slides in the casing. The pistons are moved to and fro by compressed air entering alternately through the air passages shown in the pistons. The locking apparatus is formed by the shaft C, which, at the end of the stroke of the piston F, is turned in such a manner as to completely close the air passage E. The regulation is effected by a throttle valve H inserted in the air passage G and actuated by hand.—No. 41729. May 18th, 1887.

Gas and Hot Air Engines.—*F. Wrede, Bielefeld.*—This invention relates to a new governor for gas and hot air engines. A is a rotating valve which admits the explosive mixture from the cylinder through the passage D into the space C, where it is

ignited and conveyed back into the cylinder. This valve A is connected to the spindle E of the governor by a coupling F. When the speed of the engine exceeds a given limit, this coupling is disengaged by the lever B, the connection between A and E is thereby broken, and A admits no explosive mixture into C until the speed has become normal again, when the coupling F engages and A is actuated.—No 41976. June 28th, 1887.

UNITED STATES PATENT ABSTRACTS.

Lifeboat.—*J. A. Aniello, Biloxi, Missouri.*—The new feature in the construction of this lifeboat is the arrangement side by side of three longitudinal air tight and water tight chambers. The middle chamber runs the length of the bottom of the vessel, and the side chambers are placed symmetrically at the outside of the vessel, and separated from the middle chamber and slightly above it. The three chambers are united at their ends, and passenger compartments are provided fore and aft. The inventor makes four claims for this lifeboat.—No. 376935, dated 24th January, 1888.

Double Doors.—*B. I. H. de Vry & J. Schreiber, Chicago.*—This invention supplies a method of simultaneously opening the two wings of a double folding door. Extensions are fitted to the pivot pins of the hinges, and chain wheels are fixed to these extensions where they pass underneath the floor. The chains which connect these wheels cause the simultaneous motion of the chain wheels, and hence the simultaneous opening of the two wings of the door.—No. 376947, dated 24th January, 1888.

Roofing Tiles.—*H. Schulhoff, New York.*—The tiles for the roofs are designed with an upwardly projecting tongue on one side, and with a groove corresponding to the tongue on the other side. At one end of the tile is a downwardly projecting tongue, and a portion of the opposite end extends beyond the end of the tongue and groove in the sides. In placing the tiles on the roof, the downwardly projecting tongues enter the crevices between the roof boards. The overlapping end portions and the upwardly projecting tongues and grooves on the side are caused to interlock and form a firm surface. The inventor makes three claims for these tiles and the method of arranging them.—No. 376918, dated 24th January, 1888.

Driving Belt and Wheel.—*P. Adie, London, and W. G. Henderson, Washington.*—The peripheries of the wheels are made with alternately reversed circular corrugations to fit the driving belt. The belt is composed of three longitudinal strips of metal, the two outer ones being plain and straight, and the middle one being corrugated. The outer strips are secured to the sides of the corrugated strip, so as to form continuous chords of the circular sections of the corrugated strip, for the purpose of keeping the belt in shape and preserving the shape of the corrugations. The object of this invention is to increase the grip of the belt on the pulley. The inventors make three claims.—No. 376975, dated 24th January, 1888.

Insulation of Electric Conductors.—*T. Egleston, New York.*—The wire or conductor is enveloped by an insulating fibrous covering, which is impregnated with fire proof metallic oxides and with a binding material to keep it rigid. The usual exterior coating of lead or other fusible metal is made use of for the purpose of protecting the insulator from the deleterious action of water. The inventor makes one claim for this arrangement.—No. 376818, dated 24th January, 1888.

Churns.—*W. G. Patterson, Claysville, Pennsylvania.*—This invention reduces the manual labour required to work an ordinary vertically reciprocating churn. A frame is attached to the upper part of the churn, and a horizontal lever, pivoted to this frame, is connected with the vertical piston rod of the churn. A handle at the extremity of this lever is worked up and down by the operator, and both the improved position of the operator with regard to the churn, and the extra leverage obtained by this mechanism, considerably reduces the labour exerted. There is one claim for this improved form of churn.—No. 376752, dated 24th January, 1888.

Machine for Making Collar Buttons.—*G. Krementz, Newark, New Jersey.*—In this machine the metal blanks are held in their places and rotated gradually, while a series of dies operate on them one after the other. The annexed figures show the details of the essential features of this invention. Fig. 1 represents a sectional plan of the devices for rotating the blanks, and the bars for shifting them from one die to the next; and Fig. 2 is a front view of part of the same mechanism. The die holders P and Q are fixed respectively to the reciprocating bar B¹ and to the sliding platform R. The metal blanks A¹ are held in their places by the rod K, and by the india-rubber caps G³ on the shafts G¹. The blanks are placed in their positions at the left hand end of the series of dies, and they are operated on by each die successively; the size of the dies gradually decreases from the left to the right in the figures. The apparatus in the box G serves to rotate the blank. The mechanism E E¹ E² F causes the shafts G¹ to revolve intermittently. These shafts are geared together, and are surrounded by springs which tend to press the caps G² and their india-rubber heads G³ outwards. This pressure

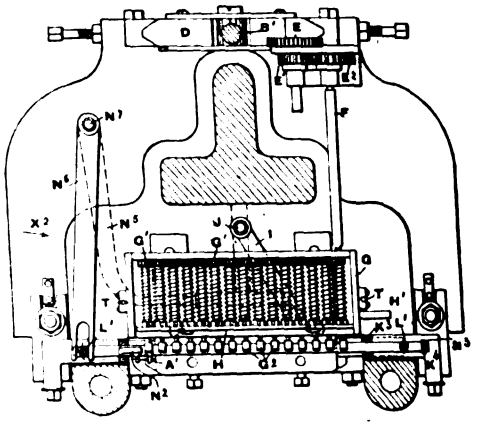


Fig. 1.

is sufficient to turn the blanks, and they are thus exposed to the pressure of the dies at all points of the circumference of their necks. The sleeves of the shafts G¹ all pass through the bar H, which is connected with end rods and cam arms. At certain periods of the action of the machine, these cam arms are actuated in such a manner as to cause the rod H to compress the springs on the shafts G¹, and so relieve the pressure on the button blanks. In front of the box G are two bars K and L. The pins L¹ project downwards, and rest on the ends of the wings M¹ of the plate M. The pins K¹ pass through apertures in L, and springs K² surrounding the pins press the bar L downwards. The bar K rests in slots in the supports K³, in one of which a vertically sliding pin N is pressed downwards by spring N¹. The arm N² projects over a part of the top edge of K, and the stop N⁴ on K³ prevents the spring from depressing N² more than a certain

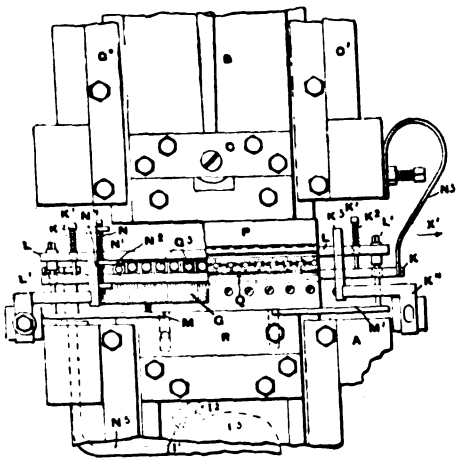

Fig. 2.

distance. The spring N³ is fastened to the frame A, and one end of it to the bar K, thus drawing K to the right. The arm N⁶ is fixed to the upper end of the shaft N⁷, and one of the pins N³ passes through a notch in the bottom of N⁶. The shaft N⁷ has a curved arm N⁸, which rests against the rim of the disc I¹. The cam I² serves to gradually raise the lower plate Q, and the sudden projection I³ allows the dies to separate during the alteration in the position of the blanks. This mechanism allows the blanks to be shifted one place to the right between two series of operations of the dies. The inventor makes nineteen claims for the reciprocating dies, for the method of rotating the blanks, and for means of shifting the blanks one position onward in the manner described.—No. 372683, dated 8th November, 1887.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. THE MANCHESTER ROYAL JUBILEE EXHIBITION.

Textile Machinery.

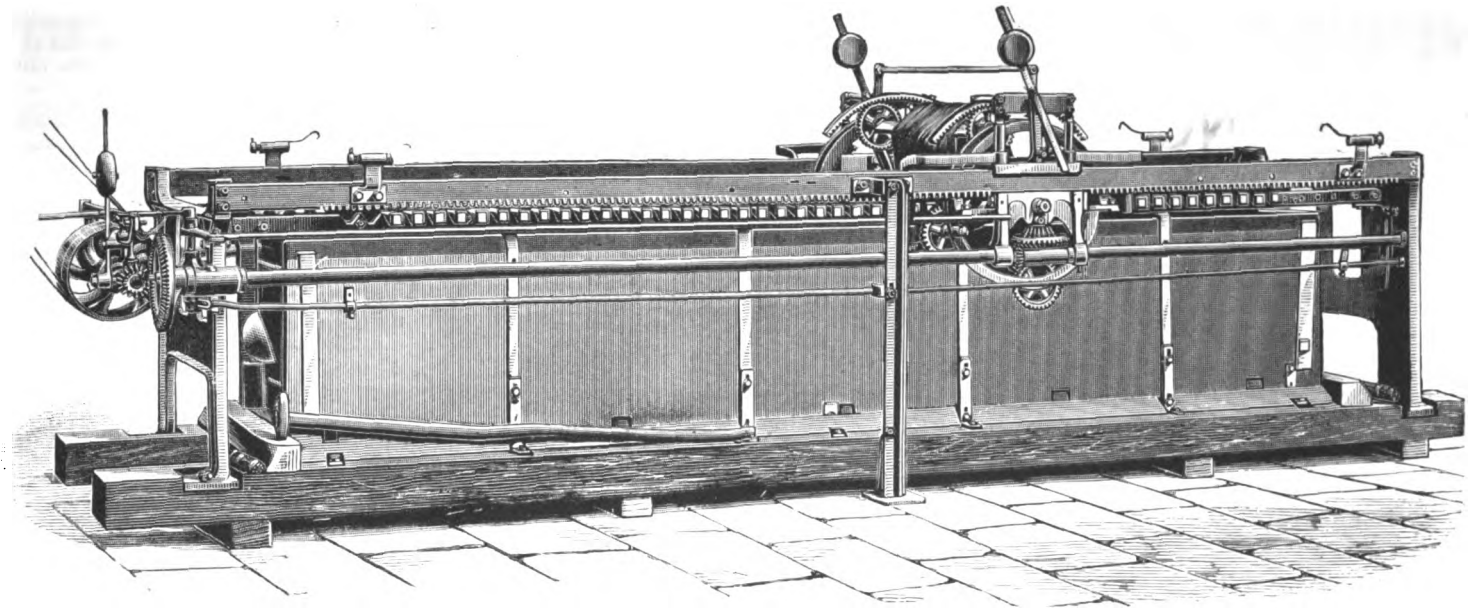

Fig. 54.

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

Textile Machinery *(continued from Vol. III., page 659).*—Having produced the yarn by one of the machines described, it may be used for various purposes. Broadly speaking, the machines exhibited for the subsequent treatment of the yarn were intended to prepare it either for weaving or thread purposes. In weaving, the weft may be used in the cop, as produced on the mule, or on the pirn, as formed on the ring frame. It may also be dyed, in which case it is wound into hanks by a process known as "reeling," and dyed, being subsequently formed into spools or pirns. The warp is wound on to bobbins with large heads, and is transferred from these on to the warp beam, on which is placed the right number of threads to form a warp for any width of cloth. Before using the warp it must be sized; and as this process is practically universal, a special form of machine is made for the purpose. If the yarn is to be made into thread for sewing purposes, it is almost always the practice to wind it from the cop on to bobbins in a special machine provided with detector mechanism, so that the required number of ends are found throughout the entire length of the bobbin. The two or more ends referred to are then twisted together in a doubling machine, and when the finished thread is produced it is wound on to reels, or made into balls for the market. If the thread be intended for lace purposes it is passed, after "doubling," through a gas flame in a "gassing" machine, by which means the projecting fibres or "ooze" is burnt off, and a smooth yarn left, or if the yarn is to be used for hosiery purposes it is wound into taper-shaped spools for use in the hosiery machines.

It is not necessary to refer to all the machines used in the various processes referred to, as some of them do not present any features of novelty. The reeling machine is well known, and does not require any special remark. It is the practice in exporting yarns to wind them in hanks on the reel, and subsequently form packages of these hanks weighing 5lb. or 10lb. each by means of a press similar to that illustrated in Vol. III., page 502. The process of dyeing the hanks was demonstrated by a machine of French origin which is known as Corron's patent, and was exhibited by Mr. Arthur Bates, of Manchester. This machine is illustrated in Fig. 54, and consists of a dyeing vat, over which a carriage, which rests on longitudinal rails, traverses. The motion of the driving belt is communicated by means of the gearing and side shaft shown to a pinion, which engages with a rack formed at the under side of the longitudinal rail. This arrangement is duplicated, and the carriage is consequently traversed equally at each side of the machine. The pinion is fixed in a stud, which is attached to the carriage, and it follows that the revolution of the pinion is followed by the traverse of the carriage. A rail with a number of V grooves is fastened to each side of the vat, the rods carrying the hanks being thus sustained. On the stud carrying the pinion a disc is mounted, and is also revolved from the side shaft. Four pinions, with their bosses shaped into sockets or holders, are suitably carried by discs, and when the latter revolve, two of the holders lift one of the hank rods out of the V in which it rests. The hank so lifted is carried forward by the revolution of the disc, during which operation the holder pinions engage with two quadrant racks, shown, and are thus revolved for a short distance. The effect of this is that a fresh portion of the hank is submitted to the action of the liquor when the hank is released by the holder. The carriage traverses at a definite rate so as to permit the holders to lift the hanks consecutively, and a stop motion is provided by which the traverse of the carriage is reversed when it has reached either end of the machine.

The machines for winding the yarn on bobbins scarcely require explanation, being generally well known. The bobbins on to which the material is wound are usually formed with a cylindrical body and circular heads or flanges, the distance between the flanges being known as the "lift." The "lift" is usually about 4½in., and the diameter of head about 4in. Messrs. Butterworth and Dickinson, of Burnley, exhibited a machine of this class. When the bobbins have been filled they are placed in a V creel to the required number, and each end is passed separately through an eye to the "beam" or roller on which the warp is wound. In the machine made by Messrs. Butterworth & Dickinson (Fig. 57), Brimelow's stop motion is used. The eyes previously mentioned are formed at the upper end of wires which, while the yarn is passing, are sustained by it. When an end breaks or fails, the wire held up by it falls and comes in contact with a revolving wiper, which is stopped in its revolution. At the end of the wiper shaft is a V clutch, the driving half of which is forced outwards when the motion of the wiper ceases. The lateral movement of this part of the clutch is transmitted to the strap fork, the machine being thus stopped. By an ingenious arrangement, as soon as the machine stops the whole of the pins are lifted, thus relieving the threads from the weight of the former. Messrs. John Dugdale & Sons, Blackburn, and Messrs. William Dickinson & Sons, also of Blackburn, both exhibited machines in which stop motions similar in principle but varying in detail to that described were used.

After the yarn has been wound on to the weavers' beams it is treated in the sizing machine. The purpose of sizing is to stiffen the yarn sufficiently to weave well, and not primarily for the purpose of adulterating the cloth, although this is one of the uses to which size is put. The sizing mixture consists of flour, tallow, wax, china clay, and other ingredients, which are used in various proportions. As the construction of the beaming machine is such that not more than five hundred ends can be wound on to one beam at a time, and as the number of threads in the warp of most widths of cloth will be five or six times as many, it is necessary to place a corresponding number of beams in the creel of the sizing machine. The yarn is drawn from the beams in such a way that all the ends are delivered to the size box from one point. The size box, which is placed between the creel and the drying cylinders, is kept well supplied with size, and is fitted with a copper roller, the under side of which is always in the size. The roller is vertically adjustable by means of a rack. After passing through the size the warp is taken between two rolls, the lower one being usually made of copper, and the upper of iron. The purpose of these rolls is to squeeze the superfluous size out of the warp, and also force the size into the yarn. After being sized, the warp is traversed around two cylinders, to which steam is admitted, and made with iron ends, and shells of tin plates or copper sheets. The course of the warp is shown in Fig. 55, this being the method ordinarily adopted. Fig. 56 shows an improved plan exhibited by Messrs. Wm. Dickinson & Sons. It will be observed that a much greater

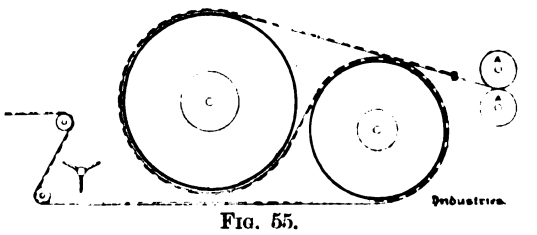

Fig. 55.

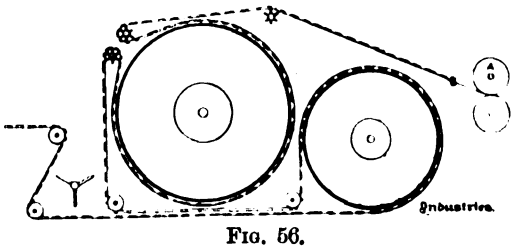

Fig. 56.

length of drying surface is secured by the latter method than by the former. Special provision is made in the construction of the cylinders for insuring the thorough removal of steam condensed in them. Messrs. Howard and Bullough showed a cylinder in which the copper shell is flanged at the ends, the flange being turned inwards at right angles to the surface. The shell is held by this flange between the cylinder end and a ring fitted inside it. The cylinder revolves on a shaft securely fixed in the ends. This firm make their bearings of a number of rollers, which are free to revolve on their own axes and round that of the cylinder. When dry, the warp is passed over a number of revolving four winged wooden fans, which are the same width as the machine. In this way the sized material is not only effectually dried, but it is also cooled to some extent. The yarn is kept in tension by means of a number of rods, and is passed through an expanding comb, after which it is carried over a roller positively driven. The weaver's beam is a roller with a wooden body and large circular iron ends, and is made wide enough to receive all the threads in the warp when laid side by side. This beam is driven by gearing through the intervention of friction plates, which will be referred to hereafter at greater length. The delivery roller is suitably driven, and the speed at which it travels regulates the amount of sizing and drying. By means of a side shaft and bevel wheels an equal velocity is given to the copper roller in the size box, so that between these two points no tension is put upon the yarn,

TEXTILE MACHINERY.

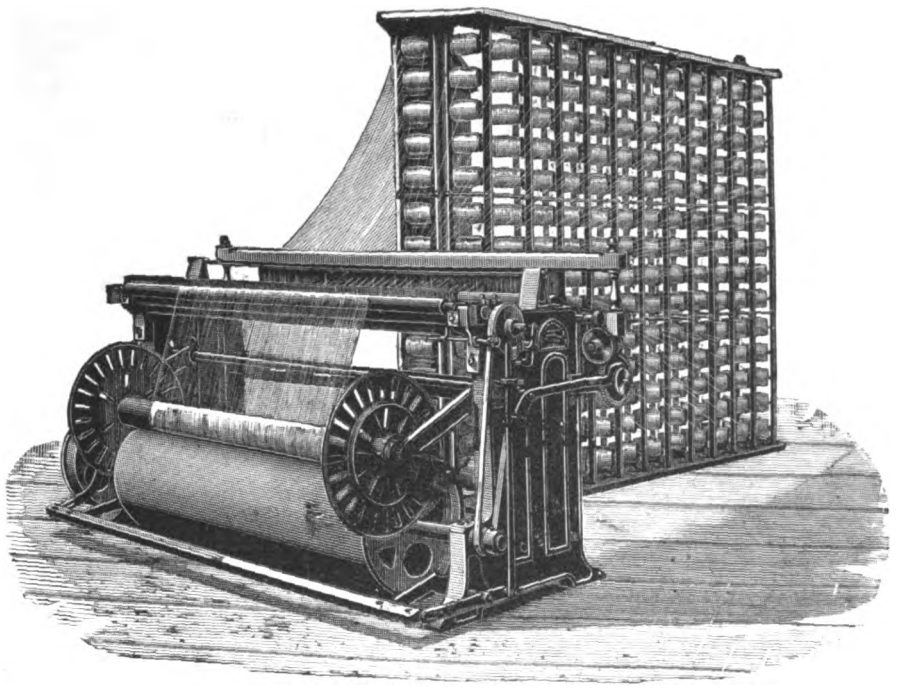

FIG. 57.

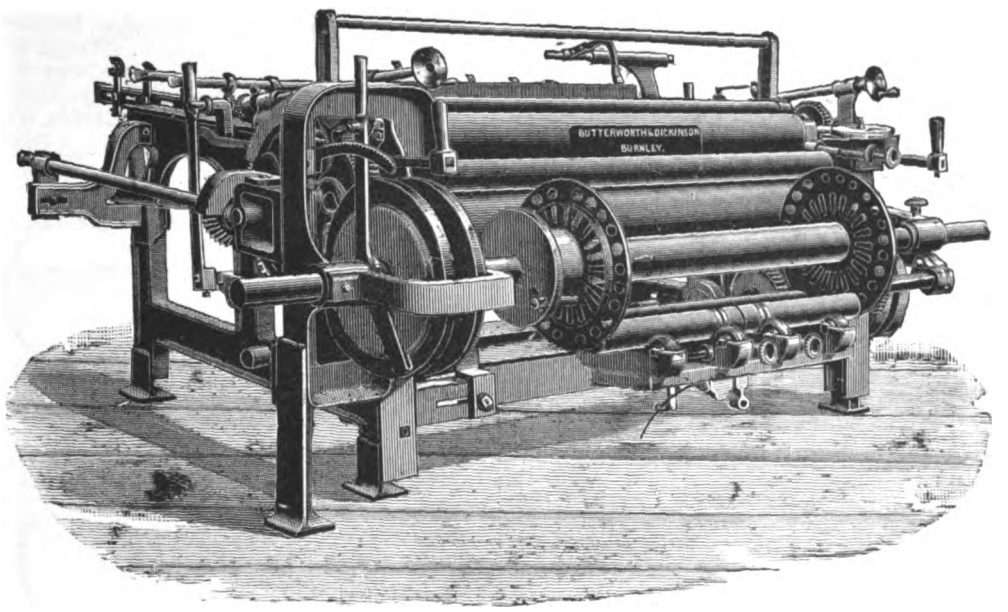

FIG. 58.

the feed being equal to the delivery. The motion is communicated to the delivery roller by means of a pair of cone drums, by altering the position of the strap on which the rate of revolution and the traverse of the yarn is altered as required. A slow motion is fitted, by which, when the weaver's beam is filled and is being replaced, the speed of delivery of the warp can be lessened. It is necessary to keep the warp always in motion, otherwise that on the cylinders would dry and bake, and thereby rendered useless. In a suitable position underneath or above the yarn on the beam are pressers, in some cases rollers and in others rods, a detailed description of which will be given hereafter. The length of warp necessary to make a piece, or "cut," being fixed, a mark is put upon the warp by a trip hammer arrangement, the fall of the hammer being obtained from the revolutions of a cam surface. The velocity of the cam is regulated by a special arrangement, to which an indicating apparatus is attached. In addition to a "cut" marking motion, there is also one for marking the shorter lengths used in making scarfs for the Indian market, known technically as "dhooties."

The friction plates referred to are placed at the end of the weaver's beam, and consist, in the case of the machine exhibited by Messrs. Howard & Bullough, of two steel discs suitably fastened to the shaft, on each side of which a disc of flannel is placed. Between these two steel discs is a double flanged wheel with a pinion in its centre, the flanges being slightly larger than the discs. With this pinion the wheel driving the arrangement gears, and two circular cast iron plates placed respectively outside each of the steel plates are arranged to be driven from the flanges of the wheel. The steel plates are fixed into a cast iron holder fastened to the shaft, on which the wheel referred to revolves. The frictional contact is preserved by a forked lever pivoted at its lower end, and weighted in a suitable manner—by this means all the surfaces are pressed together. Now it is obvious that as the wheel is revolved along with the cast iron plates, the frictional contact of the flannel surfaces will rotate the beam. When the latter is empty, or nearly so, it is not in any way retarded; but when it begins to fill it takes up at every revolution an increasing length of yarn. As the delivery roller only allows a definite amount of warp to pass, it follows that the velocity of the beam is retarded by the pull of the yarn, and the effect is that a certain amount of slip takes place in the friction gear. The taking up is constant, and a well wound beam is produced. In the machine made by Messrs. Butterworth & Dickinson (Fig. 58) the friction plate carries a bow spring, which is passed over the shaft. Alongside the spring is placed a lever, pivoted on the shaft, and having a large boss formed at its lower end, which is provided with a coarse thread. The boss fits the inside of the bracket sustaining the shaft, and in this way, as the lever is partially rotated, it moves longitudinally along the shaft and puts more or less pressure on the friction plate. The lever is furnished with a catch, which is in engagement with a notched quadrant, so that the lever can be easily set. By this device any pressure which it is desirable may be put on the friction plate.

Below the beam there are placed rollers sustained by a suitable frame, which, in Messrs. Howard & Bullough's machine, are arranged to traverse laterally, so as to alternately press the warp at each end of the beam. Messrs. Butterworth & Dickinson employ rollers, each of which is grooved at one end and rests upon narrow bowls, which can be adjusted so that the roller will come close up to the flanges of the beams. The marking hammers are driven by means of cams, the rate of revolution of which is controlled by change wheels. In the machine

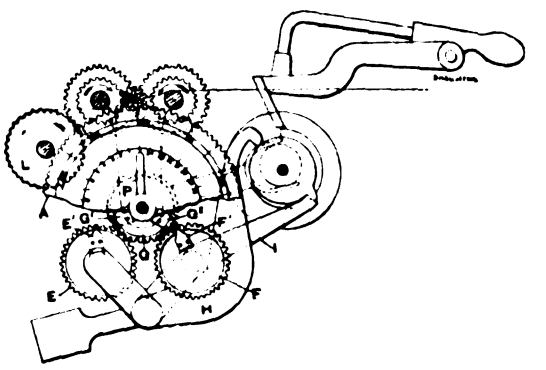

FIG. 59.

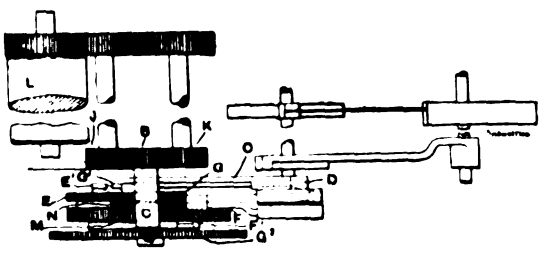

FIG. 60.

which was shown by Messrs. Howard & Bullough, and which is the invention of Mr. Alfred Hitchon, the marking motion is fitted with a new indicator, which possesses many features of merit and is very ingenious. It is illustrated in side elevation in Fig. 59, in plan in Fig. 60, while Figs. 61 and 62 show some of the details The essential part of the mechanism consists in a dial

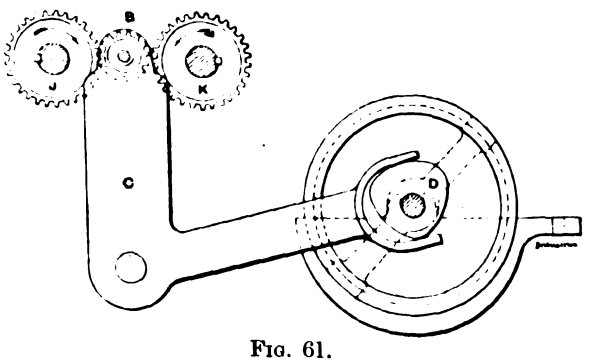

FIG. 61.

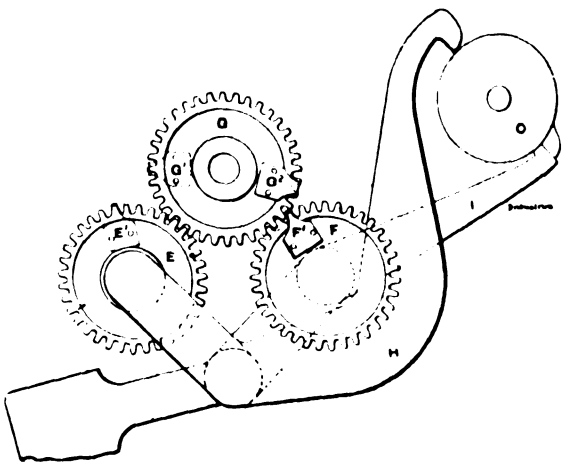

FIG. 62.

plate A, which is marked with divisions representing the number of inches of yarn passed from 1 to 100, and with other divisions each of which represents 100in., the latter set of marks being formed in a smaller circle, as shown. The edge of the dial plate A is toothed, and is in gear with a small pinion securely fixed at one end of a spindle, to the other end of which a second pinion B is fastened. The spindle and pinions are carried by a boss formed at one end of the lever C, shown in detail in Fig. 61. The other end of this lever is forked, and a cam D revolves in the fork. The cam D is fixed on the same spindle as the colour wheel,

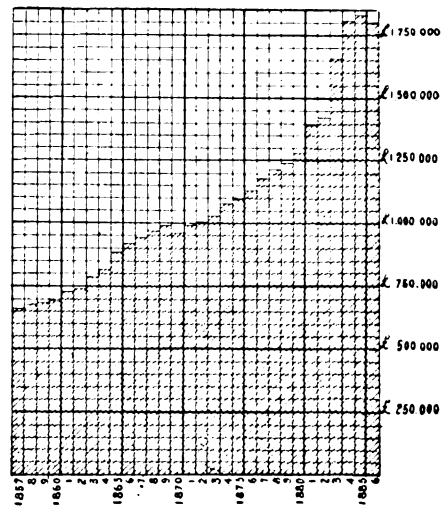
which is placed so that its under side revolves in the colour box. Referring now more particularly to Fig. 62, the wheels E, F, and G carry four additional teeth E^1, F^1, G^1, and G^2, two of which are fixed and two adjustable, all the four being set so as to project beyond the points of the teeth of the wheels. The wheels E and F are sustained by the ends of links or levers H I, each of which is suitably formed at the end to engage with the catch on the disc O. The cam D and the disc O are fastened to the same shaft, which is driven by a special arrangement of pulleys. O is held by either of the levers H I; its release by one of them will be followed by its rotation until the other engages with it; and it will therefore make a half revolution. The result is that the colour wheel is turned up so that it is in proper position to mark the warp when the hammer strikes, and also to remove the pinion B from its engagement with one of the wheels J or K, and establish a contact with the other. In this way the motion of the dial is reversed. The necessary depression of the levers H I is caused by the contact of one of the pairs of extra or projecting teeth. The pointer or finger P is attached to the boss of the wheel N, which has one tooth less than the wheel M, and derives its motion through the train of wheels shown, the pinion M being fixed on the boss of the dial A. This gear is differential, and the effect is briefly that the finger advances one figure for every 100in. measured by the roll L. When starting, the teeth F^1 G^2 are put into contact, and the dial is set to indicate the number of inches intended to be marked. Thus, if it were required to mark every 2050in., the dial would be revolved until the pointer was midway between the 20 and 21 on the smaller circle, and the mark 50 on the outer circle was at the top. The teeth E^1 G^1 would then be set in contact, the wheels re-fastened, and the machine started. The revolution of the dial would continue until the zero point was reached, when the other pair of teeth F^1 G^2 fixed on the pair of wheels F G would engage, and, by depressing the lever I, allow the cam D to make a half revolution, when the motion of the dial would be again reversed. As soon as the same length had again passed, the teeth E^1 G^1 would again come into contact, and the motion of the dial A would be once more reversed. This alternate reversal goes on so long as required, and it is thus possible to mark any length accurately and automatically. Although apparently somewhat complicated, the motion is found to be effective and reliable in practice.

(To be continued.)



THE SCOTTISH HERRING FISHERY.

II.

(Concluded from page 157.)

It may naturally be asked, what has led to the present state of the fishing industry? Much is due to the fostering care of the Fishery Board, who have jealously guarded the interests of the fishermen, and aided them by the formation of small harbours at the most dangerous parts of the coast. Though conservative, if not obstinate, in introducing improved methods of prosecuting their calling, much has yet been effected by the fishers themselves, who are a thrifty, hardy race of good seamen, our Naval Reserve being almost wholly drawn from the fishing class. Bounties were at one time given to encourage the fisheries, but they ceased more than half a century ago, and the fishermen—thrown entirely upon their own resources—have been able out of their savings to invest £1,794,000 in boats and fishing appliances. Notwithstanding the serious losses incident to the nature of their vocation, the capital invested in boats and fishing gear, as shown by the annexed diagram, has had a steady upward tendency. In 1857 the sum thus invested was £657,800, and in 1886 it had reached the very large amount of £1,794,900. This latter sum, however, includes the value of 109 beam trawl vessels, which, in some cases, are the property of companies. About forty years ago, what was then considered a good fishing boat could be purchased for £47; now, however, owing to the increased size of the craft, five or even seven times that sum is considered a small price for a boat fully equipped and ready for sea. In his report "On the Loss of Life and on the Damage Caused to Fishing Boats on the East Coast of Scotland in the Gale of 19th August, 1848," the late Admiral Washington gives information regarding the dimensions, cost, and crew of the fishing boats then in use. The largest boats did not exceed 34ft. keel, and all of them were open; while many of those used on the coast of England were either whole or half decked. The fishermen generally on the East Coast had a rooted aversion to anything but open boats, and it was long before their prejudices were overcome. The first full decked boat was built at Eyemouth, little more than thirty years ago, and it was such a decided success as regards safety in heavy weather, and greater shelter and comfort to the men, that others speedily followed. The above tables give the dimensions of boats at various places as used in 1886 and 1848.

Value of Boats, Nets, and Lines, from 1857 to 1886.

Between 1848 and 1885 the boats greatly increased in length of keel, from 34ft. to 50ft. and even 59ft., with a relative increase in the draught, carrying power, and cost. Instead of costing only £60 to £95, the prices now vary from £200 to £400. Twenty years ago there were 13,132 fishing boats in Scotland, the tonnage of which was 101,909; while in 1855 there were 5309 of 30ft. keel and upwards, with an average tonnage of 17·9; 4311 of 18ft. to 30ft. keel, and 5807 of 18ft. keel and under. This shows a healthy state of the industry, since the boats have not only increased in size, but are better equipped and manned; they carry a larger fleet of nets, and can go to distant fishing grounds previously untried. At one time only the inshore waters were fished; now, however, distant ventures are made, with a correspondingly larger catch. One objection to decked boats has yet to be fully met; the want of permanent or temporary portable bulwarks to prevent the men losing their footing and being washed overboard in heavy weather is still unsupplied. Various expedients have been suggested, but as yet the fishermen have not been induced to do much in this direction, the allegation being that the proper working of the nets will be interfered with. Nothing can be simpler than a set of temporary standards with eyes through which a chain might be run, and these could be removed when not required. Some change will certainly require soon to be made in this respect, as the loss of life due to the want of some bulwark protection is considerable.

The use of steam or other motive power will doubtless have a wider application than at present, notwithstanding the fishermen's objections to its use. Steam power is used for collecting and taking to market fresh fish, and also for towing the boats to sea and bringing them back to harbour. A more liberal use of this means of getting the boats quickly to port is desirable, especially when the fish are to be cured for branding. At Eyemouth, during the height of the season of 1884, no fewer than twenty-six steam tugs were employed towing the boats, at a cost of £1,100 a week; and it may be stated that the catch in the Eyemouth district for that year was higher than formerly, and amounted to 84,112 crans, about one-fourth being sold fresh and the remainder cured. A valuable fishing is often lost owing to the boats being becalmed, especially when they are at the distant fishing grounds. Not only have the boats been greatly increased in size, but the nets have been also increased in length and area, so that the means of capture of each boat have been augmented five-fold. Until about twenty-five years ago the nets were made of hemp twine, 40 yards long by 6 to 7 yards deep, and each boat carried twenty-four. Now the nets are of cotton, each of the value of about £3; they are 60 yards in length by 10 yards in depth, and each boat carries sixty to seventy of them, presenting 36,000 square yards of surface. This increase in the drift of nets has not, however, added to their weight. There are frequently 5000 to 6000 boats fishing in the North Sea, the nets of which, if extended in one line, would go four times the distance between Liverpool and New York. The size of the mesh, which should be 1in. from knot to knot, is still in dispute, and the proper size to admit of shrinkage after "barking" has not been defined.

There is a dark side to this picture of progress. From the nature of his calling, the fisherman is often in peril. Much property and many valuable lives are lost annually in the prosecution of the fisheries. A sudden gale may sweep over the coast, bringing ruin in its train; and though sudden calamities are happily few in number, yet every year has its victims, the annual tribute being about fifty men, and, unfortunately, sometimes more. These disasters have, however, led the men to pay more heed to the indications of the barometer. The gale of October, 1881, was unmistakably indicated by the state of the barometer, and its warning voice was disregarded, with fatal consequences. The gale of 1848 led Admiral Washington to suggest improvements in the build, size, and better equipment of the fishing boats, and these improvements have been steadily adopted. But there is a limit beyond which the size of the boats cannot well be pushed; for, as most of the East Coast harbours are dry at low water, or nearly so, the boats may require, in certain states of the tide, to leave the fishing grounds earlier than they would do if the harbours had the requisite depth at the entrance to enable them to enter at all states of the tide. Closely connected with the proper prosecution of the fisheries is the provision of adequate harbour accommodation. This subject was fully reported on by the "Harbour Accommodation Committee, 1882-84." The committee recommended the provision of deep water accommodation, but this most desirable object is not easily attained on the eastern seaboard of Scotland, unless at great cost entirely beyond the resources of the fishing community, even aided by a grant from the Fishery Board out of the £3,000 annually placed by Parliament at its disposal. This vote, small though it be, has, by stimulating local effort, enabled the Board to provide small harbours and quays at some of the most necessitous parts of the coast, and has resulted in immense benefits to the fishermen. Much, however, remains to be done in providing suitable harbours. Before concluding we should state that the figures on the right of the diagram shown on page 156 represent hundreds of thousands, and not millions, as incorrectly stated in our last week's issue.

RAILWAY CARRIAGE AND WAGGON WORKS.

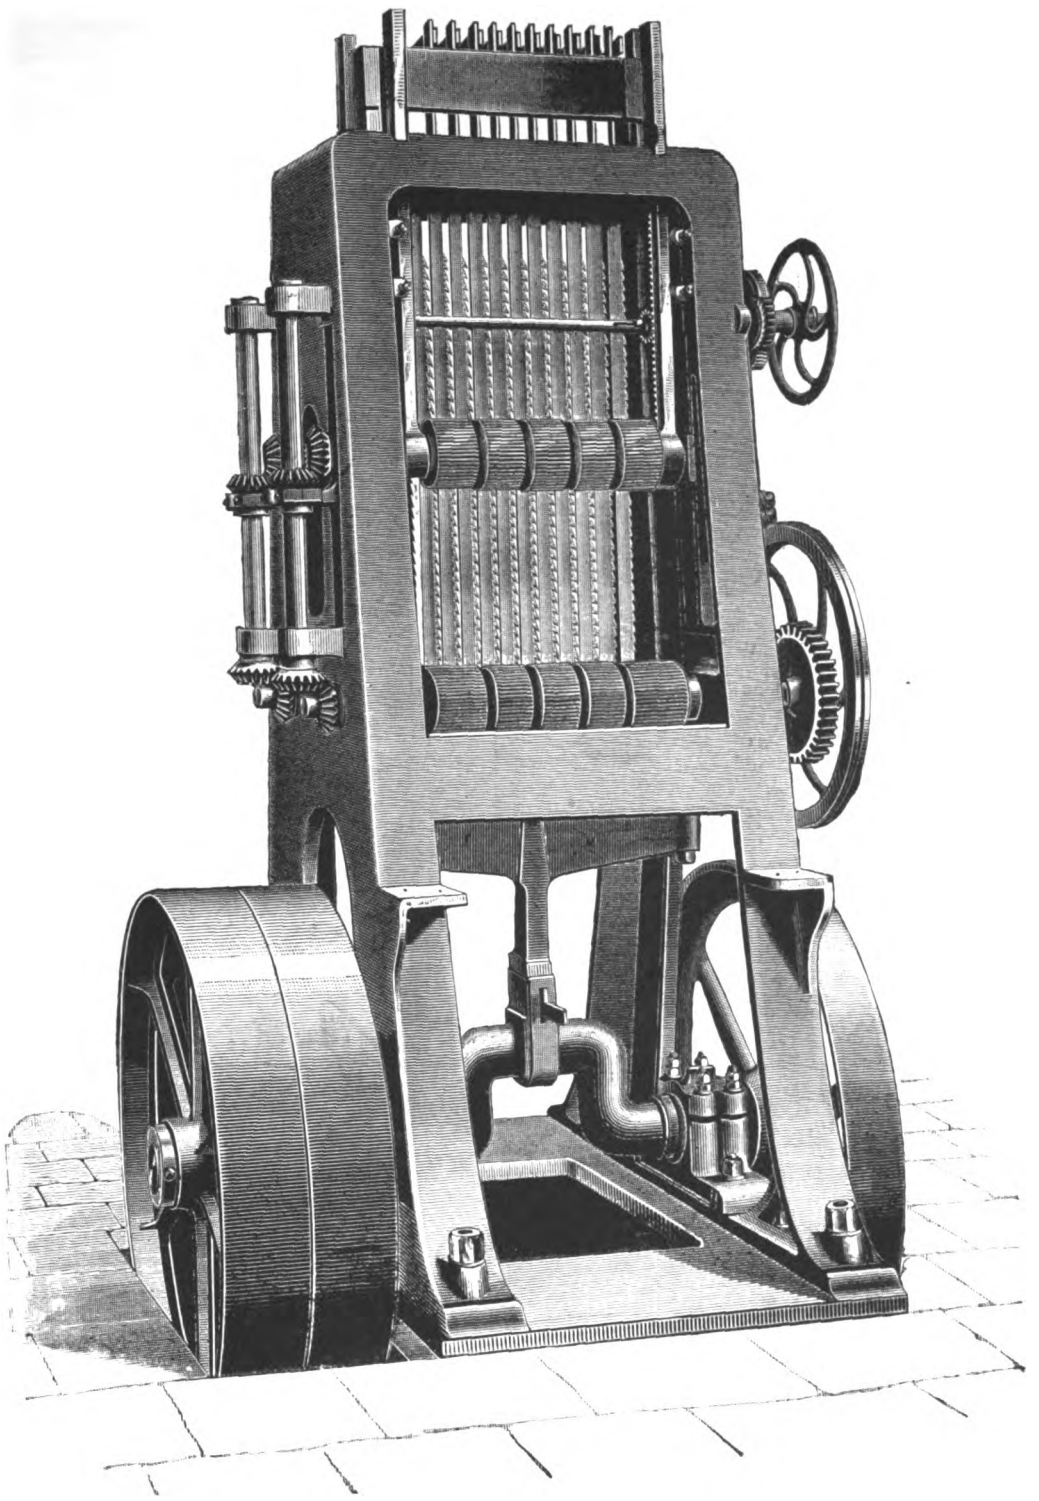

Fig. 5.

RAILWAY CARRIAGE AND WAGGON WORKS.

By M. Powis Bale, M.Inst.M.E., Assoc.M.Inst.C.E.

II.

(Continued from page 159.)

The combined log, deal, and flitch frame can be used in sawing the carriage and waggon soles, sheathing, &c., as well as cutting flitches, planks, and boards. The main frame of this machine should be of massive construction, to withstand the great strain and absorb the very considerable vibration of working found in all wood working machines with a reciprocating motion. The base of the frame should be extended. The best form of crank shaft—which should be made either of good wrought iron, free from seams, or of steel—is the double or bell crank, with a bearing placed well up to the crank on either side. An additional bearing should be placed on the outer side of the driving pulleys. Cranks bent by hydraulic pressure are considerably stronger and to be preferred to the block crank. In the best practice the crank shaft is connected to the saw frame by a pair of rods, one on either side of the frame. This arrangement secures the advantage of a long connecting rod, with increased strength and ease in working, the power being applied directly when it is required, viz., when the saws are cutting. This plan has also the advantage of lessening considerably the depth and cost of the foundations necessary. The saw frame should be of steel, and combine, as far as possible, strength with lightness. Steel of hollow section can be recommended, and in calculating the compressive strain the swing frame has to bear, the maximum number of saws the frame is proposed to work must be allowed for with a considerable margin for contingencies, or the frame may be found to spring in work. The stress on the saws is very great, often amounting to five or six tons per blade. The bearings in which the swing frame works should, by preference, be made of phosphor bronze, and be adjustable for wear. The connecting and side rods should be fitted with straps and cottars and with bearings of phosphor bronze. A very important point in log frames used for connecting native and hard woods is the feed gear. I can, from experience, recommend what may be termed a multiple roller feed, which I believe was first introduced in Austria, and consists briefly of two pairs of top and bottom feed rollers, all of which are driven, being geared together. In this arrangement a most powerful feed is obtained, obviating slip when sawing difficult or frozen timber. The illustration (Fig. 5) represents a compound roller feed log frame, from the designs of Messrs. Haigh and Co., Limited, of Oldham. The chief point of interest in this machine is the feed gear, which consists of duplex sets of rollers, the whole of which are driven by positive gear, thus almost entirely doing away with the chance of the log slipping, even if of a difficult nature or in bad condition. The feed gear is so arranged that its speed can be increased or reduced whilst the log is being sawn. In this machine the old plan of weighting the top rollers by means of levers and weights fixed on the top of the machine has been dispensed with, and the weighting apparatus is now applied on either side of the frame and within reach of the sawyer. The sweep crank shaft is of steel, and is fitted with two balancing fly wheels, one on either side of the frame, and the saw frame is driven by means of side connecting rods.

A matter of great importance in the effective working of log frames, steam mortising, and other machines with a vertical reciprocating motion, is the foundations. These should be carefully made of stone or brick work, to overcome the vibration and punching action of the machines when at work. Stone is preferable to brick work, and should be carefully dressed. If the dressing is badly done, and the pressure is uneven and severe, foundation stones are liable to fracture. Blocks of stone of long dimensions in proportion to their thickness should not be used, as with heavy machines with a reciprocating motion, and sometimes with a positive stroke or dead blow, the risk of breakage is considerable. A safe rule is to make the length of the block about three times the thickness, and the width one and a half times. Great care should be taken that the stone is accurately levelled, and set as nearly as possible perpendicular to the direction of the stress. The top blocks should be cramped together and filled in with molten lead. The framing of the machine should be made to combine as far as possible, and be made integral with the foundation. The quantity of the work turned out, and the longevity of the machine, depend more on the stability of the foundations than is generally imagined. In machines where there is a constant punching action going on, the dead weight on the foundation should not exceed one-sixth of the crushing load, and a course of timber balks should be put over the masonry, so that the machine does not rest directly on the stone or brick work. A sheet of lead placed between the machine and the foundation will lessen vibration. The foundation bolts should pass entirely through the masonry.

For breaking down heavy logs, large band sawing machines have latterly come into extended use. They possess several advantages over circular saws, the chief of which are that they take much less power to drive, and waste much less wood. The chief difficulty experienced in working large band saws is keeping them to a true vertical line; but this may be overcome by fitting special guides where the saw enters and leaves, and by proper arrangements for receiving the back thrust of the blade. The main frame of the machine should preferably be a cored casting, made in one piece to secure freedom from vibration in working. A very important factor in efficient working lies in the construction of the saw wheels. These should combine as far as possible lightness with strength, and be of not less than 6ft. diam. In the best practice they are made of wrought iron or steel. They must be perfectly in balance and mounted elastically. For heavy machines the author prefers to arrange the saw wheel spindles each to run in two pairs of adjustable bearings, instead of allowing the wheels to run overhung on studs as is sometimes done. If the work is difficult, and the saw is found to run out of line, in addition to the ordinary saw guides, two pairs of movable steel rollers, placed immediately above where the saw enters the wood, and below the table, may be used with advantage. It is found in practice that a thin gauge saw will stand better than a thick one, and one with rounded gullets better than one with angular gullets, as these latter are much more liable to commence cracking at the roots of the teeth. It is important that a constant and even tension be given to the saw blade; but this must be elastic and not rigid, to allow for the expansion of the saw by becoming hot in working, and its contraction whilst cooling. Saw blades should always be slackened out after finishing work. For sawing oak, ash, elm, and hard woods generally, a saw blade with more teeth should be used than to saw soft wood, and these filed further back. For woods with a woolly fibre saws with deep teeth and coarse space should be employed, to allow of easy clearance to the saw dust. With large band saws a blade speed of 5000ft. per minute for soft wood, and 4000ft. for hard wood, will generally be found suitable. The illustrations Figs. 6 & 7 represent a vertical band sawing machine for cutting heavy logs into flitches, boards, &c., made by Messrs. Haigh & Co., Limited, of Oldham. The main frame of the machine is a strong hollow casting made in one piece. The saw wheels are of wrought iron, covered on the face with hard wood, and an outside covering of india-rubber for the saw blade to run on. Each saw wheel spindle is mounted in double bearings adjustable for wear. The top saw wheel is arranged to rise and fall, and fitted with a canting arrangement, and also a weighted

Digitized by Google

RAILWAY CARRIAGE AND WAGGON WORKS.

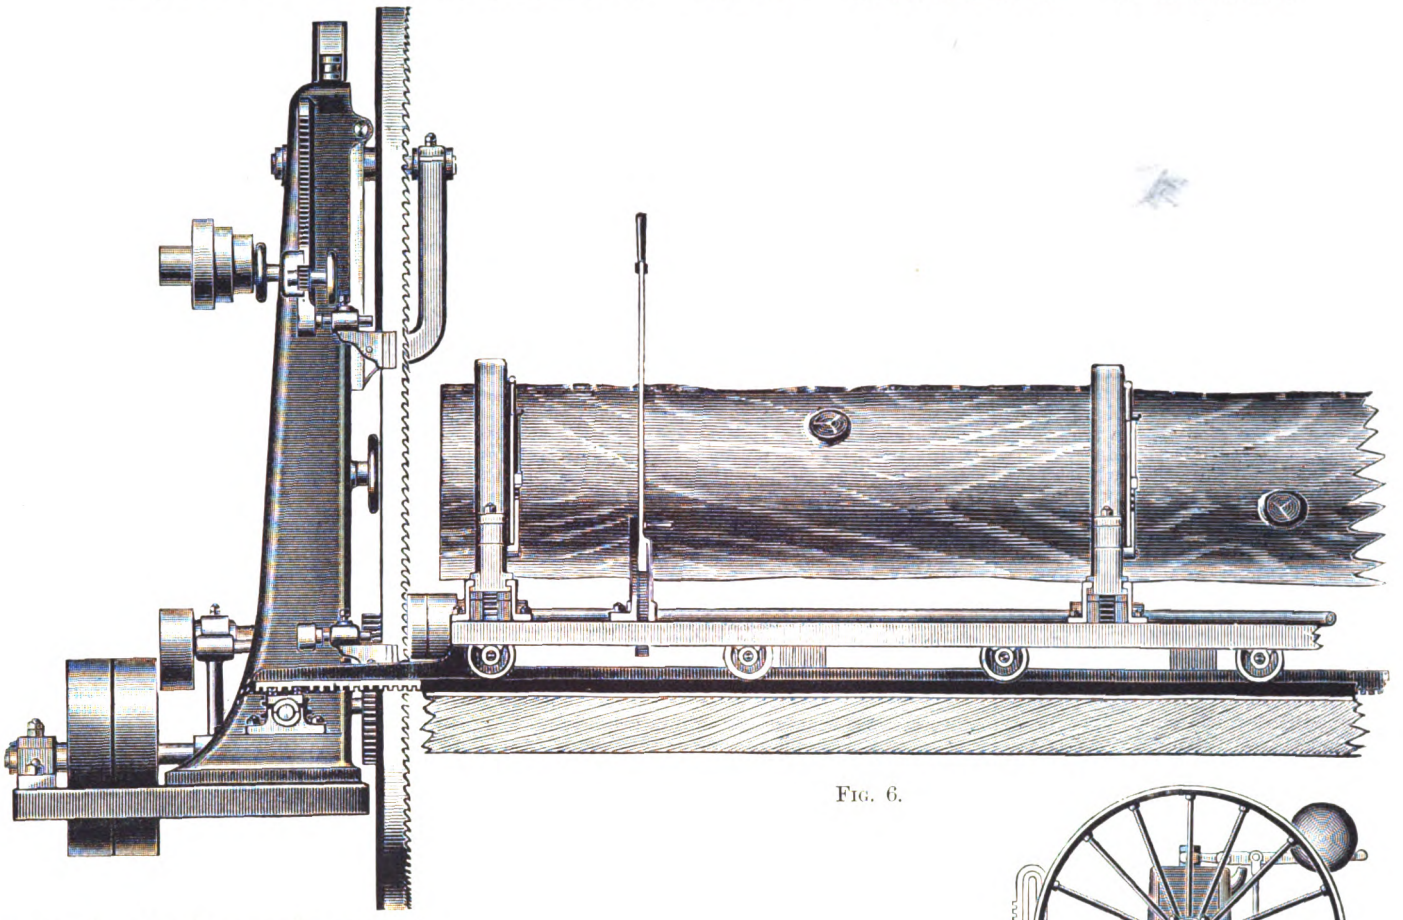

Fig. 6.

tension apparatus, to allow for the expansion or contraction of the saw blade. The saw guides consist of anti-friction rollers of steel, which receive the back thrust of the blade, and hard wood adjustable packing pieces placed on either side of the saw where it enters and leaves the cut. The log to be sawn is mounted on a wrought iron travelling carriage driven by worm gearing, which can be thrown in or out of motion by means of a friction clutch and lever. Three rates of feed are arranged to suit different kinds of wood. The log is held in position by means of adjustable dogs attached to sliding heads. These can be brought into action simultaneously by means of a lever, or separately should the log be crooked. For breaking down heavy timber, a combination of the rack feed circular saw bench and a band sawing machine has recently been introduced with considerable success. In this combination the same travelling table for carrying the timber is employed for both machines, and either the circular or band saw can be used as desired, or as the nature of the work demands, the rate of feed being regulated accordingly.

The horizontal single bladed frame is found particularly useful in opening out logs, cutting panels, and more especially when the wood is valuable, as the attendant is enabled to examine the figure and soundness of the wood after each cut; and should a defect or unsoundness be found, the machine can be stopped, and the log converted to better advantage into scantling or other pieces. The machine takes little power to drive, and as a thin blade can be used, very little wood is wasted.

(To be continued.)

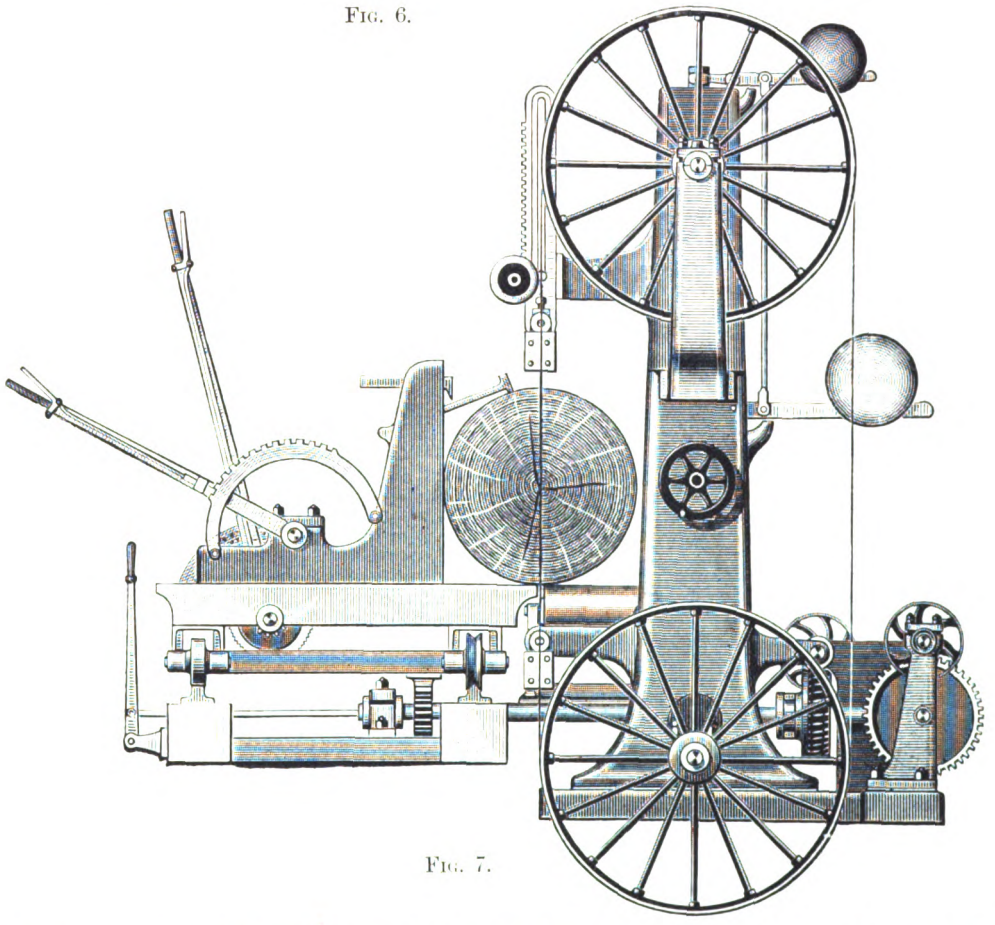

Fig. 7.

MOULDS' PATENT COAL GETTER.

Mechanical coal getters are not so plentiful in the collieries of this country as on the Continent, partly owing to certain physical exigencies and partly to the purer atmosphere which, as a rule, prevails in the mines here. The tendency of modern legislation and of current public opinion, however, is to dispense with the use of powder for getting minerals, and although the inventions of water and gelatinous surroundings have provided a comparatively satisfactory safeguard in this connection, there can be no doubt that the introduction of an efficient mechanical arrangement for breaking down coals without resort to the use of explosives would be a boon to the mining community; although our experience goes to show that no small proofs of its competence and efficacy would be required before the prejudice—amounting almost to bigotry—which exists amongst both managers and men in favour of explosive force could be overcome. Mr. Enoch Moulds, manager of the Whitebarn Colliery, Newcastle, Staffordshire, has recently patented a coal getter which is certainly worthy of trial by colliery proprietors as a substitute for explosives, more particularly in gaseous or dusty mines. The machine is constructed on the wedge system, only with this difference between it and the ordinary application of that principle—instead of working with a forward action, involving the liability of breaking away the front of the coal only and thus getting it bit by bit, this appliance is so constructed as to exercise an outward pressure, *i.e.*, a pressure from back to front. Supposing the coal to be holed, the piston cylinder of the getter, 3in. in diameter, is inserted, and by means of inclined planes the coal is gripped at the far end of the hole and then rifted backward to the face by the aid of hydraulic pressure. The result is an increase of the proportion of large coals obtained, and the shattering influence of an explosive is obviated. The quantity of water required to work the hydraulic jack is three quarts, and by an ingenious self containing arrangement one supply is sufficient for an indefinite period. The parts of the getter are few in number, simple in construction, and of great durability, being made of annealed steel. One great drawback to the extensive adoption of mechanical contrivances for coal getting has been the weight and unwieldy proportions of those hitherto tried; but as the machine now under notice only weighs altogether 102lb., no exception can be taken to its portability. With regard to the question of cost, the patentee claims that in spite of the necessary original outlay required for its adoption, the use of his coal getter has pecuniary advantages over that of explosives, regardless of its important bearing upon the proportionate yield of large coal and slack.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 21st February, 1888.

The Iron Market.—The iron market has developed no new feature since my last report. There is steady progress visible all round, both in the demand and in the movement of prices. The Paris trade in building iron is strong and active, and promises to become more animated as the season advances. The latest accounts received from the provinces show that there is a cheerful tone in nearly every branch of the iron industry. The growing demand for crude iron has occasioned great activity in the Longwy district, where the blast furnace owners are rapidly increasing their output.

The Copper Trade.—Much uneasiness is felt by manufacturers concerning the future of this trade since it became known that the syndicate had succeeded in the project of bringing about a combination among the principal mine owners. The prospect is now one of high prices for some time to come, and of restricted trade in consequence and a subsequent disorganisation of the market by over production of copper. It is hard to see how the mine owners can obtain more than a temporary and very brief advantage from such a combination—an advantage for which they will have to pay dearly later on. The declaration of the Government that they will take proceedings against the syndicate if a case of monopoly be proved in this matter, has given general satisfaction.

The Sugar Bounties.—In previous letters I have expressed my conviction, resulting from observation among the manufacturers and agriculturists of the North, and information of a trustworthy character, obtained here, that the French Government will not agree to the proposal emanating from the British Government, to abolish the bounties system. Every day brings fresh proof of the strong feeling against this measure, and shows more clearly the weight of the opposition which would have to be encountered. A petition to the Ministers of Commerce and Industry and of Agriculture is now being signed—and that itwill be signed by all the manufacturers and agriculturists interested, there can be no doubt—from which I extract the following clauses: "These projects (the increase of 10fr. per 100 kilo., and the abolition of the bounties), the immediate effect of which has been to stop short all dealings between beet growers and sugar manufacturers, have called forth grave apprehensions on our part. The first is indeed a flagrant violation of the contract concluded between the beet growers and the State, on the faith of which numerous business engagements have been entered into by the growers and the sugar manufacturers. The second, which is directed exclusively against France by foreign competitors, would ruin our agricultural industry, which has of late made every possible effort to struggle against its strongly protected foreign rivals, and which would in a few years recover its position, if only assured of that security without which no progress is possible. We protest therefore, first, against the Bill of the Minister of Finance; and, second, against every notion of an international convention with England in this matter of the sugar trade. England is in this business the accomplice of Germany, and the project has been put forward with a view to check the development of our sugar industry. We therefore pray that the law of the 14th July, 1884, may be preserved in its integrity."

BERLIN, 20th February, 1888.

The Iron Market.—The most important event which has recently taken place in the iron market is the union between the Silesian and Westphalian sheet makers, the immediate result of which was a rise of 2s. per ton. Sheets are now quoted at 150s. The home market will now be shared by the two groups in the following way: The eastern portion of Germany will be exclusively supplied by the Silesian makers, the western portion by Westphalian makers, and the strip between by both. An agreement was also arrived at by the different associations of wire nail makers on the basis of 150s. per ton. In Upper Silesia no change has taken place in the crude iron market, and the number of furnaces in blast remains at twenty-eight, as in the previous week. There is a brisk demand for iron ores, notably for the brand known as "Minette," which is raised in Lorraine, and which is specially suitable for the Thomas process. Ores from the Siegerland and the Nassau districts are also in good request, and have slightly risen in price. Business in crude iron remains satisfactory, and the syndicated works have now sold their production to the end of the second quarter. They do not accept orders at present prices further ahead, and are practically masters of the situation, since the stocks of crude iron are completely cleared. Foundries are well employed, especially with pipes for mining purposes. In wire nails the home market is good, but the export trade shows no tendency to improve. Steel rolling mills are busy, in consequence of the recent orders for rails received from the State railways. In other railway material our own manufacturers do not seem to be able to exclude foreign competition. Only a week ago an order for six third-class passenger coaches was carried off by Messrs. F. Beynes, of Harlem, at £460 each, delivered free at Cleves, whereas the old established firm of Herebrand, of Cologne, quoted £467. The fact that such a trifling difference in price turned the scale shows that our railway administrations do not allow patriotic motives to influence them in their business. The Düsseldorf Railway Supply Company has recently obtained an order for eight first and second class passenger coaches at £730 each.

Electric Lighting.—The first central station in which accumulators are used has been recently started in Berlin, at No. 37, Neue Friedrichstrasse. The plant consists of two 45 h.p. Babcock & Wilcox boilers (manufactured by Messrs. Schmidt, of Küstrin), two steam engines of 35 h.p. each, and two 18 kilo.-watt dynamos. The current is not supplied direct from the dynamo, but from a battery of flat tray pattern Khotinsky accumulators, each cell having 600 ampère-hours' capacity. The principal customer at present is a restaurant situated under the elevated railway, and a total of five hundred lamps is now installed; but applications for the light from neighbouring places have been received, and to provide for the extension the battery boxes have been made deep enough to admit additional plates, by which the capacity can be increased by another 600 ampère-hours. The lamps used are 150-volt Seel lamps, and the total cost of the central station and mains was £3,500, that is, at the rate of £7 per lamp fixed.—A few weeks ago I gave particulars of the electric light installation in what is known as the German theatre of this town. I am now enabled, by the courtesy of the engineer in charge, to give you details of the installation and working expenses. When gas was used in this theatre, the cost for lighting varied from £4 per day in summer to £5. 10s. in winter; but now, with the electric light, the working expenses do not materially vary with the season, as the items of attendance and interest on the plant is a constant. The total cost of the installation was about £3,000, and this contains the following items: Engine house and chimney, £500; boiler and engines, £940; dynamos, wiring, and accessories, £905; electric light fittings, £250; and regulator for the stage, £150. The consumption of coal in winter is about 16cwt. daily, costing 18s.; attendance, 8s.; lubricant, 3s.; and interest on the capital outlay 20s., reckoning this at 10 per cent. for three hundred working days. The installation has been in use too short a time to estimate accurately the cost of renewal of lamps, but this could hardly exceed 10s. a night, so that the total expense for the electric light may be taken as £3 per night, which is considerably below the sum previously paid for gas.—At a meeting of the Town Council, held on the 16th inst., it was resolved that the wiring of private houses may be left to open competition, but that the work in connection with bringing the current into the house and the installation of the meter must be undertaken by the Berlin Electric Company.

VIENNA, 20th February, 1888.

The Coal Market.—After a week of comparative stagnation, the coal market is again beginning to revive; but during the last few days severe snowstorms have somewhat interfered with the traffic. The coal traffic on the Northern railway is a fair gauge of the general prosperity of the manufacturing trades, and in this connection it is satisfactory to note that the consignments of coal re-exported from the Northern goods yard have, during the past month, been greater than they have ever been before. As much as 5000 tons were dispatched in a single day, the average for previous years being about 2000 tons per day only. The increase in traffic is partly due to the recent reductions of freights on this line, which were resolved upon mainly with a view to enable the Southern railways to obtain Silesian coal. This has caused some stir among colliery owners in Styria, who have hitherto supplied the Southern lines, and the Government has been asked to protect them from the competition of their northern rivals. The Minister of Finance, however, seems unwilling to interfere. The interest threatened is, moreover, not of very great importance, as the total quantity of coal raised in Styria averages only about 1,700,000 tons annually. At the present moment the exports of coal from Vienna are greater than the imports, and stocks are decreasing in consequence. The total traffic on the Northern railway amounted during 1887 to 838,000 tons, of which 127,000 tons were taken by the Imperial Continental Gas Association of this town. The average quantity of coal and lignite raised annually throughout Austria amounts to about 15,000,000 tons, the value of which is estimated at nearly £3,000,000. In this sum Bohemia participates with about 50 per cent., Silesia with 17 per cent., and Styria with only 14 per cent.

The Iron Market.—The general feeling of the iron market is hopeful, and the revival of trade is confidently expected. At the present time, however, there is comparative stagnation, owing to the lines being blocked by snow and the bad condition of the roads. There is a good demand for crude iron at previous prices, and in bar iron there has been a rise of 7s. per ton. For sheets, both black and tinned, the demand is very brisk. A few weeks ago I reported the important contracts between the State railways and the Alpine Company, the Tetschen Works, and the Witkowitz Company for the supply of rails during 1888, and the first batch of orders has now been given out at the price then stipulated. There is a good prospect for railway contractors, and at the present time the following mileage is in course of construction: Private lines, 285 miles; Government lines, 122 miles; total, 407 miles. The total number of hands employed in these works is 18,000.

Textiles.—Notwithstanding the drop in the price of raw cotton, spinners are unwilling to make concessions, and keep the prices of yarns at the previous quotation. The same is the case with thread. Spinners have a good many orders on hand, and are thus enabled to resist a demand for a reduction in price until they have filled their present contracts. Wool has declined, but in silk goods trade is becoming more brisk. The linen market in Trautenau is firm, and large transactions have taken place.

Exhibition of Railway Material.—As I reported at the time, an exhibition was held last year at Buda-Pesth for the purpose of bringing before Hungarian manufacturers a collection of the various accessories required in the working of railways, with a view to their being eventually manufactured in the country. This exhibition has been a success, and the experiment is to be renewed at the forthcoming Jubilee Exhibition at the Rotunda. Railway appliances have been shown at all previous exhibitions, but more or less scattered about in the various sections. Now, however, the intention is to bring all such exhibits together in one group.

Electrical Engineering.—Herr Fischer, a civil engineer of this town, has obtained a concession for an electric railway between Vöslau and Rauhenstein, near Baden, and from there to Leopoldsdorf. The length of the line being considerable, Herr Fischer will probably use storage cars; Julien accumulators are now being tested in the Electrotechnical Institute, and a trial of these cells for tramway work in competition with Reckenzaun cells will shortly take place. A central station for the supply of electricity has recently been erected at Neuhaus, in Bohemia. The contractor is Count Czernin, a landowner in that district, and he has arranged for the supply of light to the Commune for twenty years. Power is obtained from a turbine, and there are at present two dynamo machines installed. The distribution is on the three-wire system with feeders. All the leads are carried on poles overhead. The streets are lighted by eighty-five 16 c.p. glow lamps, and in private houses there are at present 365 lamps fixed, but the demand is constantly increasing. To provide against breakdown a battery of 1000 storage cells is now being laid down.

BRUSSELS, 21st February, 1888.

The Coal Market.—Prices continue very firm, and colliery owners decline to make contracts for forward delivery at the current rates, which are 15s. 2d. to 16s. 8d. for large household coal, 8s. 10d. to 9s. 7d. for unscreened household coal, 5s. 9d. to 8s. for unscreened coal for industrial purposes, 9s. 7d. for small coal, and 11s. 2d. to 12s. 10d. for coke. The exports of coal from France to Belgium are increasing, and French coal is specially gaining ground in the Escaut and La Lys valleys, with Ghent as the centre of consumption, and the Hainault collieries are losing their customers in these districts. The progress of Belgian exports to France is not so marked. Last year 100,000 tons more were sent to France than in 1886; but the latter year showed a decrease compared with 1885, owing to the Northern and Eastern railways of France having reduced their rates, and thus having enabled French coal to replace Belgian in some of the French markets.

The Metal Market.—Business is very satisfactory, and orders continue to flow in, especially to rolling mills. No. 1 bar iron is quoted at 80s. per ton, girders at 88s., No. 2 sheets at 116s., steel rails at 88s., steel tyres at 108s., and steel axles at 116s. Blast furnaces are busy. New and important contracts for the Belgian State railways are announced. Negotiations are in progress for the purchase of the works of the Société du Midi, at Charleroi, by the Thy-le-Château Company; the works include two blast furnaces in working order, and one hundred coke ovens. The price is £24,000. A syndicate is being formed at the Brussels Exchange to work the mines of the Orange River Free State, and to establish there some leading Belgian industries. The construction of the railways required for the development of this scheme would furnish employment for our works.

The Brussels Exhibition.—The contractors for the buildings have during the last few days been pushing on operations more actively, and the machinery section and the horseshoe building are rapidly being finished. Good progress is also being made with the annexes. A private Belgo-German syndicate is busy arranging the aquarium, casino, and German breweries which are to be included in the Exhibition. The Paris Hippodrome has contracted to give daily performances, and will use their own lighting plant from Paris, which is chiefly remarkable for its great complications, there being a separate dynamo for almost every arc lamp.

Tram Cars at the Brussels Exhibition.—On the tram line in the gardens of the Exhibition mechanical traction will be employed, the system adopted being that of M. Charles Legrand, of Mons. In the buildings and annexes, cars of the type known as Jardin d'Acclimation, in which the passengers sit back to back, will be used. The weight of this car, including eleven passengers, is 33cwt. The accumulators weigh 6cwt., and the motor and gearing about 5cwt. For these small cars, which will travel at the rate of about 4½ miles an hour, the energy required is estimated at 800 watts, or slightly over 1 h.p. For the convenience of changing the cells the latter are arranged in four groups, which are inserted and withdrawn from the ends of the car. There will be forty cells, each weighing complete 16½lb., and containing 13lb. of plates. The maximum discharge current is 10 ampères, or about three-quarters of an ampère for every pound of lead. The speed will be regulated by changing the grouping of

Digitized by Google

accumulators so as to obtain either 20, 40, 60, or 80 volts. The type of the accumulator chosen is that of Somzée; the motor will be either a Mourlon, Pieper, or Dulait machine. M. Halot will supply the track and car.

Sewage Disposal.—A new system of purifying sewage and the waste water of factories has been invented by M. Defosse, of Brussels, which is very simple, and the cost of which it is claimed is more than covered by the value of the extracted matter. The process consists of three stages. In the first, the solid matter is precipitated in settling tanks, by means of some cheap chemicals. The second stage consists of filtration through a bed of turf, specially prepared, and capable of being cleaned and used over again for an indefinite number of times. In the third stage the product is passed over a bed of spongy iron. The purified water passes away to the river through a channel containing broken limestone. The chemicals employed are oxidising agents capable of precipitating not only the matter held in suspension, but also a part of that in solution. The precipitate is removed by special machinery.

DÜSSELDORF, 20th February, 1888.

The Coal Market.—The coal market is still characterised by extreme animation. All classes of coal are in strong demand, and prices are slowly but steadily advancing. The activity in the iron trade occasions a large consumption of the industrial kinds, particularly coking coal. But the return of wintry weather has so stimulated the house coal trade that it is for the moment scarcely less animated than that in the classes suitable for industrial purposes. Great efforts are being made to obtain a reduction of the railway rates to Hamburg and Bremen, where Westphalian produce comes into competition with English. The increase in exports of coal in 1887 was nearly balanced by the increase in the imports, the additional quantities being 126,140 tons for the former, against 114,450 tons for the latter. But the coke imports were less by 1358 tons, while the exports increased by 84,480 tons. These changes indicate growing activity in the coke making industry. Nearly the whole of the falling off in the imports of coke is to be found in the trade with Great Britain.

The Iron Market.—The iron market exhibits no symptom of weakness. The demand continues brisk for all classes of goods, increases even in some directions, and prices have an upward tendency. There are no indications of a reaction. Manufacturers appear to have no misgivings concerning the course of trade in the near future. The prevalent belief is that the current year will be throughout a period of uninterrupted activity. The German iron market forms a striking contrast to the English, the continued weakness of which is a cause of surprise here; but it does not give rise to apprehension. Crude iron of all sorts is in strong demand. Spiegel is less inquired after on home account, but more important transactions have taken place of late for export. Forge pig continues to be the class most sought after; it can no longer be bought at the syndicate base prices. Some large dealings have been reported within the last few days at 53s. for delivery in July. White steel pig is quoted at 52s. Bessemer is now more inquired after, and prices exhibit a tendency to advance. Business in finished iron and steel has lost none of its animation, but manufacturers complain loudly of the present prices, which, since the last rise in crude iron, leave but a small margin of profit. As for the export trade, that is wholly profitless. Plate makers are doing better since the rise of 5s. as also reported last week. This rise has not checked the demand for plates, which for the moment are the class of goods most actively dealt in. The wire nail syndicate has issued a circular to customers, requesting them to address all inquiries and orders either to the sales bureau at Berlin or to that at Hamm. The former, Delbrück, Leo, & Co., Nos. 63-65, Mauerstrasse, Berlin, W., is for the home trade, and for Denmark, Sweden and Norway, Roumania, Servia, and Bulgaria, exclusive of East Roumelia; the latter is the export bureau for all other countries. The proposed combination of the Silesian with the Rhenish-Westphalian sheet rolling works is now an accomplished fact, so that the whole of the German sheet iron trade is controlled by syndicates.

Flax and Yarn Market.—A better demand has sprung up for the coarser flax yarns, and spinners have been able to obtain higher prices. Low yarns are specially sought after. The finer numbers are for the moment neglected. On the whole the markets are not animated, but there is a steady course of business. There is great activity in Russian flax, the low rate of exchange being favourable to buyers.

LILLE, 21st February, 1888.

Textile Manufactures.—There is not much to be said of the business in textile goods this week. The markets generally have been lifeless, partly on account of the carnival, and partly in consequence of the wintry weather which has set in again. The current week will probably show better results. Letters I have received from Roubaix show a complaining tone. It is said that the situation of woollen goods is scarcely as satisfactory as it was. The markets are dull and heavy, and there are no indications of immediate revival. Fortunately the export trade continues active. Excepting the case of cotton fabrics, the January exports exhibit a marked improvement compared with the same month of last year. The following are the declared values, the figures within brackets denoting the values for January, 1887: Woollen goods, £1,051,240 (£829,040); silk goods, £704,560 (£688,240); cotton goods, £319,240 (£364,360); linen and hemp goods, £32,680 (£28,080); and jute goods, £6,240 (£7,400).

Flax and Yarn Markets.—Activity is still the characteristic feature of the flax market, so far as home grown produce is concerned, and prices are strongly in favour of sellers. The demand is chiefly for Walloon flax from Douai and Bergues. Russian is not much inquired after, and prices exhibit a tendency to recede. The Ghent market is animated and strong for home grown flax, and spinners are again buying Russian more largely. There is some business doing in tows, but principally in the fine numbers. Yarns are in fairly strong demand. Spinners have some difficulty in delivering fast enough to meet contracts in hand. Prices are very firm. Jute yarns are still much sought after.

The Iron Market.—The rise in prices which followed the establishing of the syndicate of manufacturers in this district is now confirmed by the adhesion to the combination of the manufacturers of other localities. Buyers no longer hold out for concessions on the current rates, on the contrary they are eager to purchase in anticipation of a further advance. The important order for 20,000 tons of pig iron, bars, and plates, obtained for the Panama Canal Company by the firm of Eiffel, has had a stimulating effect upon French industry. Founders are very busy. The founders' syndicate for the arrondissement of Lille held a meeting last week to consider a proposal to extend the combination over the whole region of the North, and this proposal was unanimously adopted.

The Coal Industry.—The coal industry of the North of France exhibits a constant growth, and the statistics of production for 1887 are very satisfactory. The output of the department of the Nord amounted to 4,274,726 tons, against 3,978,175 tons in 1886, while that of the Pas-de-Calais increased in the same time from 6,463,214 tons to 7,146,666 tons. Thus the total production in 1887 amounted to 11,421,392 tons, nearly a million tons more than in 1886, or an increase of 9·4 per cent.

Production of Sugar.—The official statistics of the production in January afford additional proof of the accuracy of the estimates based upon a low yield of roots in 1887. The total production now amounts to 319,766 tons, against 388,218 tons last year, a falling off of 68,442 tons in refined sugar. Reduced to the crude, these quantities represent about 373,000 tons, against 453,000 tons in 1887, a difference of 80,000 tons. It now seems hardly possible that the whole production of the year will reach 400,000 tons of crude sugar.

AMSTERDAM, 21st February, 1888.

The Transvaal Gold Fields.—A Dutch syndicate has purchased large tracts of auriferous land in the Transvaal, and has sent Mr. Hulshoff, a pupil of the mining school at Clausthal, to Pretoria to make the necessary arrangements for working the mines in an economical and methodical manner.

The Utilisation of the Dutch Moors.—In some of our provinces there are large tracts of heath and moorland which at present have no value whatever, although once covered with dense forests. An effort is now being made to utilise these moors, and several land owners have combined to form a company, whose object it will be to attempt a gradual fertilisation of the soil by re-planting trees. How much good such an enterprise can work under careful management is shown by a similar undertaking in Denmark, which has been in existence for the last quarter of a century. The Danish society for the fertilisation of heaths and moors, chiefly by forestation, has now some 4000 members, among whom may be found the principal agriculturists of the kingdom. It enjoys large subsidies from the Government and from the agricultural societies, so that it has been enabled to start some four hundred "concessions," or plantations, in different parts of Denmark. In the Netherlands it is proposed to work the scheme upon similar lines.

MADRID, 20th February, 1888.

Sale of Mines and Iron Works.—The Quiros Coal Mines and Iron Works are offered for sale at £50,000. They cost the French company, which at present owns them, about £200,000; but the business has never proved remunerative, the management having been bad. The site is very good, and phosphoric iron could be made at a price which would compete favourably with the best Cleveland. Under English management, ores would not cost over 2s. 6d. in the furnaces, and coke could be made on the Simon-Carvés system at 9s. per ton, allowing for the value of the tar and ammonia.

Spanish Coals for Italy.—Signor Gandolfi, an Italian engineer connected with the Terni Steel Works, is visiting the principal coal basins in Spain, in order to ascertain if Spanish coal would be available for the 300 Simon-Carvés coke furnaces which it is proposed to erect at the works. It is, however, very doubtful whether we could export coal to Italy, as the coals in the North cost more to obtain than English, while those of the South, though cheaper, have a long land carriage before they can be shipped. In my opinion Spanish coal will never reach Italy unless there is a general rise in English coal of at least 2s. per ton, or unless a large company were formed to acquire southern collieries, which would build its own railway to a seaport. Scanty and dear food is also one of the causes why the cost of production of coal is above that of England.

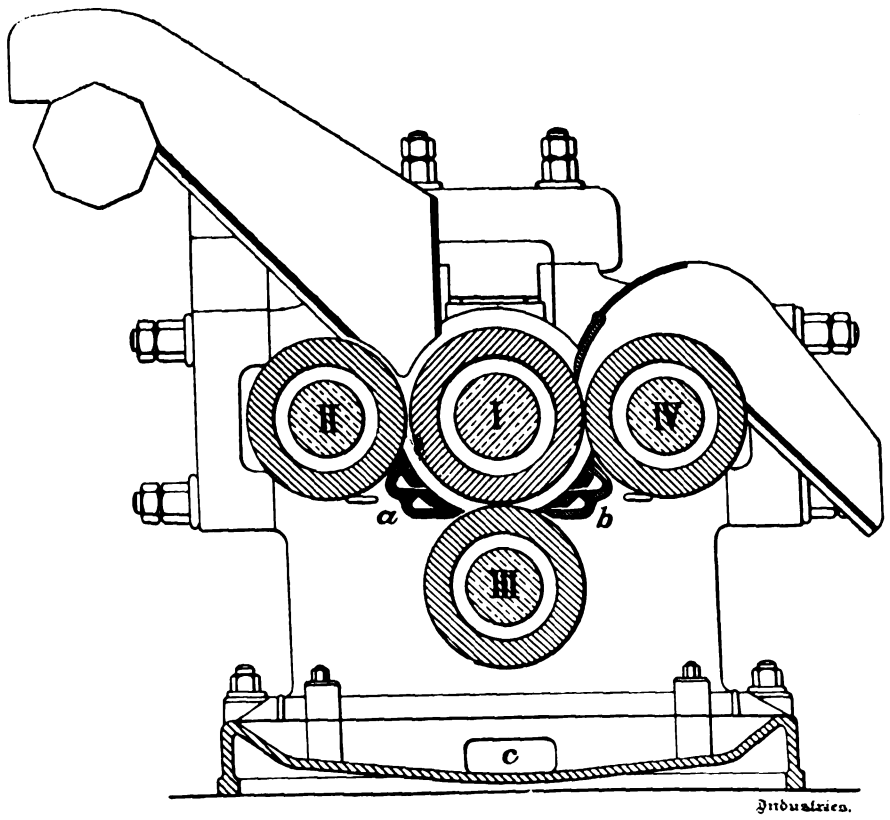
Telephony.—Telephone systems are being adopted rapidly by our principal towns, and offers are now invited by the Government for an exchange station at Cordova. So far we have no long distance lines, and a network uniting Madrid with the large seaports, such as Barcelona, Cadiz, Bilbao, and Carthagena should prove profitable.

Electrical Company.—The Sociedad Española de Electricidad, which was established some years ago with a capital of £400,000, and which has been a losing concern from the first, is to be re-organised. It is doubtful, however, if the proposed arrangement would leave the new capital free from the consequences of the mistakes which have been made in the past.

NEW YORK, 11th February, 1888.

The Coal Market.—From the trade standpoint the anthracite market could not be in better condition, the strike in the Schuylkill region having caused, until within the last few days, an almost entire suspension of production, and this, together with the stoppage in the Lehigh Valley, has thrown the demand entirely on the Wyoming district. All the collieries there are running full time with increased force, and even then are unable to meet the demand. The fact that violence is being resorted to by the miners who have struck is a pretty sure indication that in a short time they will be again at work. A good trade is being done in bituminous coal at fair prices. Coke is in good demand; many of the iron works heretofore using anthracite coal are now obliged by its scarcity to use coke, thus opening temporarily a new market for the surplus production of the coke regions.

The Iron and Steel Market.—Business during the past week has been of a decidedly favourable character, resulting in largely increased orders for specialties; but it is not likely that the current prices will be maintained after the miners' strike is ended. In pig iron the scarcity of good brands is becoming very marked, and although there is plenty of iron in the market it is difficult to obtain the quality which customers are in the habit of using. This scarcity will probably increase, as many furnaces are banking up, the complaint being poor coal. This month finds more furnaces in the Lehigh Valley out of blast than at any time since 1884. There are now twenty-one furnaces out of blast and thirty-two still in blast, but some of these may be blown out any day. With the discharging of men from the blown out furnaces there has been a corresponding decrease in the demand for ore, and a consequent shutting down at the mines or a partial suspension of work. The cost of producing pig from such fuel as can now be obtained is estimated at from 4s. to 6s. per ton more than it is usually, and an inferior quality is also produced. Prices are about the same as last week. A leading company which a year ago had booked orders for over 100,000 tons has now sold only 25,000 tons ahead, and this is to supply one contractor for the whole year. There is a good deal of inquiry for manufactured iron, but the amount actually placed is not very great. Prices are steady, owing perhaps rather to increased cost than to increased demand, and are 1·9 to 1·95 cents per lb. for best refined bars. The steel rail mills have pretty generally sold the allotment of 800,000 tons made by the committee last summer, and some of them are unable to take any orders until a new allotment is made. Prices are 131s. to 137s. per ton; but the lower rates are very unsatisfactory to makers. The total sales to date for 1888 delivery amount to between 350,000 and 400,000 tons.—The official report of the imports of iron and steel for last year includes 340,000 tons of scrap iron, an increase of 2·50 per cent. over 1886; 137,829 tons of steel rails, an increase of 240 per cent.; 310,551 tons of steel ingots, &c., an increase of 530 per cent.; and 21,675 tons of cotton ties, a gain of 110 per cent.; pig iron imports have increased 30 per cent., bar iron 25 per cent., tin plates and wire rods each about 10 per cent. — In the Bill to be introduced by Chairman Mills, of the Ways and Means Committee of the House, to "reduce taxation and revise the tariff," it is proposed to reduce the tariff on pig iron from $6·72 per ton to $4·50. There will be strong opposition even among Democrats to the change in the iron duty, and it is not probable that this feature of the Bill will become law.



The Metal Market.—The price of copper still remains at 16·5 to 17 cents per lb. for present delivery, with a fair amount of business, and there seems to be no prospect of a fall in price. Sales to the amount of 100 tons have been made in tin at prices ranging from 35·9 cents per lb. for spot to 33·10 to 34·50 for futures. Lead is quiet, with but little business, prices varying from 4·90 to 4·97½ cents per lb.

Manufacturing Works in Baltimore.—The City of Baltimore is attracting the attention of large manufacturing interests. The new steel works at Sparrow Point, within easy reach of the city, have attracted the attention of other manufacturers. There is some talk of moving the Strong Locomotive Works to that city, and Mr. Simpson, of dry dock fame, contemplates starting a large establishment there.

Trial Trip.—The new steel steamship "Owego," of the Union Steamship Company, which recently made a trial trip on Lake Erie, is one of the largest and most powerful boats on the lake. She measures 352ft. over all, 41ft. beam, and 25½ft. depth of hold. She is fitted with triple expansion engines.

IMPROVED FOUR-ROLLER CANE MILL.

FOUR-ROLLER CANE MILL WITH MACERATION APPARATUS.

In the ordinary three-roller cane mill the sugar canes are supposed to receive a preliminary crushing between the first and second roll, and the final crushing between the second and third roll; but in many cases the first roller is little more than a feeder, thus leaving the entire grinding or crushing to be done at one pressure by the megass roll. In the improved mill, which we illustrate above and on page 192, and which is made by Messrs. George Fletcher & Co., of Poplar, London (Fletcher & Leblanc's patent), the cane is subjected to three distinct pressures, viz., the first between rolls II and I; the second between I and III; and the third between I and IV; thus dividing the work into three stages and insuring a greater yield of juice. The opening between the rollers for the first pressure is from $\frac{3}{4}$ to $\frac{7}{8}$ of an inch as in the ordinary mills; the opening between the rollers for the second pressure is about $\frac{1}{8}$ of an inch, and that for the third pressure may be $\frac{1}{16}$ of an inch or less. The juice is collected in the base plate, and taken off by the channel C, and if maceration be desired it can be commenced in the mill itself by injecting steam into the hollow trash turners *a b*, situated at the back of the megass knives. The three outer rolls are made adjustable by means of wedge blocks set up by bolts. The wedges are also made adjustable by worm gearing and hand wheels, so that when the mill is working a "choke" can be avoided. The stresses are not taken directly by the cast iron frame, but are resisted by wrought iron bolts, so that in case of accident the damage is limited to the breakage of a few bolts. Should any accident occur to one roll this only becomes disabled, and the mill can still be used as an ordinary three-roller mill. As will be seen from the perspective illustration, on page 192, the axle of the middle roll is driven in the usual way, the power being transmitted to the other three rolls by spur gearing.

One of these mills has been tested on the Alexandria estate in Cuba, and we learn from a report of Mr. Francisco de Arrieta, a local sugar mill engineer, that the yield of juice was 78·3 per cent., and of megass 21·7 per cent. The cane was of fourteen or fifteen months' growth, rather hard, short jointed, and scarcely one inch thick. Judging from its appearance, Mr. Arrieta estimates that it contained 13 per cent. of fibre and 87 per cent. of juice. The bagasse on its delivery from the mill formed a perfectly homogeneous layer composed of small pieces of fibre so free from moisture that it could be used directly as fuel without previous drying. He considers that the Leblanc & Fletcher's mill will enable the planter to compete successfully with the producers of beet root sugar, owing to the increased yield of juice, which he estimates at from 15 to 20 per cent. over the yield obtainable with the ordinary cane mill.

THE INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting, held on Tuesday, the 14th of February, a paper was read on "The Economic Use of the Plane Table in Topographical Surveying," by Mr. Josiah Pierce, jun., M.A., Assoc.M.Inst.C.E. The author stated that the plane table, being one of the most ancient of surveying instruments, needed no introduction. However, he desired to direct attention to its wide and economical use on nearly all Government surveys, and to the fact that experience had proved that, within certain practical limits, plane tabling was the most rapid, accurate, and economical method of executing topographical work. The modern plane table, when properly constructed, was an altazimuth instrument of precision; with it the horizontal projections of existing angles were recorded graphically, free from errors of record, adjustment, and plotting. The problem of plane tabling was, simply: given a board and a ruler, construct a map. The most important geometrical laws applied in practice were those of similar figures. Three or more points being joined on the map, the requirement was that the figure thus produced should be the horizontal projection of the lines joining similar points in nature. Also, if lines were drawn from any other point joining the points of this polygon, a similar point should exist in nature where the observed angles would be exactly the same. This important condition was theoretically fulfilled when homologous sides in the two figures were parallel. To prove the necessity of placing the plane table "in meridian" at all stations, the problem of orienting by three known points was demonstrated mechanically, and a working model was exhibited to illustrate all cases of the three-point problem. When a triangulation existed of the country to be mapped, a projection was laid down on the plane table sheet, on a given scale, of the network of triangles, provision being made for the convergence of the meridians by suitable projection. In American practice the trigonometrical system thus projected was tested and corrected graphically before being accepted as a sufficiently accurate base for the detail. Radial lines to salient points were drawn, with corresponding vertical angles in all directions from the stations occupied. The intersection of two rays on the same point being an elementary location, a third ray through the same point in a well-conditioned intersection placed beyond doubt the accuracy of its position. Thus, in the operation of plane tabling, constant opportunities occurred of checking locations without calculation, and the scale was ever present in all directions to control the amount of detail to be gathered; in addition, a complete record of the area surveyed appeared, advantages which were to be found in no other system of mapping. When the scale of map was large, minute details could be more profitably located by the stadia rod in horizontal position and altitude with surprising accuracy and rapidity. Whether by method of intersection alone, or combined with linear measurement, the operations were continued until a sufficient number of points had been located to satisfy the requirements of the map, beyond which it was purely an artistic sketch. Between the points located in altitude, as well as in position, equal-interval contours were interpolated, drawn and corrected from nature; this system was almost universally applied, and was especially valuable in mountainous regions. To illustrate the character of the topographical work done in the United States, typical maps and sketches were exhibited, showing almost every variety of physical feature, constructed either on the plane table, or on plane table principles. An unavoidable source of error peculiar to the instrument was the atmospheric or hygrometric effect on the paper or instrument used. In the United States a favourable climate had added not a little to the success of the methods pursued. The requirements of a plane table of precision were the same as those of any other type of altazimuth surveying instrument. By comparison of a number of types, the maximum stability and portability appeared in the U.S. Coast and Geodetic Survey pattern, and for mountain service a simple and efficient instrument, recently adopted by the U.S. Geological Survey, deserved examination. The theoretical requirements in setting a plane table over a station were: (1) That the plane of the board should be horizontal. (2) That the station on the map should be vertically over the point on the ground. (3) That the meridian of the point on the plane table sheet should be in the plane of the meridian of the station. Of these requirements the first was met by proper construction, the third by adjustment in azimuth. To meet the second—the adjustment for eccentricity—numerous mechanical contrivances had been designed, of no practical value, and only lending additional weight and increasing the liability of error. The plane table was not well adapted for traversing, owing to the difficulty of eliminating the eccentricity, which produced serious azimuth errors at short range; but by proper precautions the error could be confined to one of geographical position, inappreciable on any common scale. To secure accurate results in plane tabling, it was necessary to confine azimuth errors to minute quantities, not exceeding 1″ or 2″, which would pass unobserved within the limits of the plane table sheet. This degree of precision could only be secured by proper construction of the levelling movement alidade. An examination of the sources of error in measuring azimuth angles with a theodolite or plane table, showed that the most serious source of error arose from an inclination of the transverse axis which supported the telescope. With an alidade in proper adjustment, practically the same errors would be produced if it was used on a plane table not properly levelled. The effect of the board being out of level and the telescope confined to a horizontal plane, was that the rule and telescope would only indicate the same direction at four points, which case was illustrated mechanically by Hooke's joint. In such a case the board might be out of level 15° before the maximum error in azimuth would amount to 1°, which showed that a rough reconnaisance plane table should give good results in a flat country; but for mountainous regions an accurate levelling movement was required. For measuring altitude angles the alidade designed by Professor Hilgard was most accurate. Recent results and improvements showed beyond doubt that a far greater degree of precision could be obtained from simple graphic triangulation than was commonly supposed, amply sufficient for purposes of mapping, and with a degree of economy unequalled by other systems. The colonial engineer and student could ill afford to lose sight of a valuable and simple instrument, with which he could, alone and unaided, construct a topographical map on any scale, with a degree of precision only limited by the scale, and in the same time that he would occupy in taking observations with other instruments. An appendix to the paper contained, among other matter, statistics gathered from official reports relating to the use of the plane table, and an account of a plane table survey of the Lake Mono region, illustrating the construction of an accurate map entirely on geometrical principles, without reference to scale or linear measurement. In illustration of the paper, a collection of instruments was exhibited, comprising several varieties of plane tables, Portuguese alidade, alidade with solar, Porros' tacheometer, Jähn's vielmesser, Howlett's stadiometer, Francis' clinometer, omnimeters of various sizes, Edgworth's surveying instrument, Colonel Richard's cavalry sketching board and others, dipleidoscope, prismatic compass, theodolites, and other instruments used in topographical surveying.

OUR BIG GUNS.

Our readers may recollect that we made some remarks on this subject in our issue of the 10th inst. In *The Times* of Friday last there appears an important letter from Mr. E. H. Carbutt, President of the Institution of Mechanical Engineers, on the same subject, which we give below:—

You stated on the 1st inst. that an accident had occurred at Woolwich at the proof butts to a 10in. gun—viz., that the lining tube had been blown out to the rear. No official statement has yet been made, but I understand that the gun really burst. The inner tube or lining being in two pieces, the gun gave way at the junction, and the jacket or covering opened up; the whole of the rear of the gun was blown off. That is to say, the gun exploded just forward of the trunnions, and was shattered for its whole length beyond them. Now, sir, I have previously called attention to this faulty method of constructing the lining tube in two pieces, which was certain to cause accidents sooner or later. The gun was made to the Woolwich design by Messrs. Armstrong. Is the defect due to design or workmanship? It is, indeed, a very serious thing that one of our newest 10in. steel guns should have burst; but if the report which is now current about our guns is true, we are indeed in a lamentable position.

It is reported that the A tube or liner of every one of the new 9·2in. guns which has been sent to proof has split. I cannot find out how many, but understand that nine guns have so failed. And, further, that one of these 9·2in. guns which had passed the proof and was lying on the wharf, ready to be shipped to one of our colonies, when lifted up by the crane to be put on board the ship showed a crack the whole length of the gun, not in the A tube or liner, but in the jacket. Not being in Parliament, I cannot ask if these reports are true, but I have ventured to send them to you (as they reach me from two entirely different sources) in the hope that the Secretary of State for War will give the public a full and correct account. On the 22nd of March, 1886, I moved for a Committee of

Digitized by Google

the House of Commons to inquire into the whole question of our guns. The then Secretary of State for War, Mr. Campbell-Bannerman, declined to open up the question of design, saying they were so satisfied with our design that they could not allow the subject to be inquired into. Within a month the 43-ton gun of Her Majesty's ship "Colossus" burst.

The authorities at once ordered all the remaining 43-ton guns which had been issued to be returned to Woolwich to be rebuilt, and greatly strengthened them and also the new guns by chase-hooping them. Now that the present series of accidents has occurred, may I again ask, is the present Secretary of State for War satisfied that our design is right? Lord Morley's Committee (of which I was a member) was prevented going into the question of design, but we went very fully into the question of manufacture and the control of the Government workshops. The main conclusions of the Committee (I believe I state correctly) were that inspection should be separated from manufacture, and that it should be the same for private firms as for the Government works; that military men should manage military matters; and that engineers should be responsible for mechanical or constructional matters. Let me quote the first two recommendations, which were approved and signed by every member but two of that Committee:—

"1. That a superintendent of ordnance factories should be appointed, holding office under the Director of Artillery and Stores. He should be an officer of the Army, and should reside at Woolwich. He should be the sole channel of communication between the War Office and the manufacturing departments. In addition to the general superintendence of the factories, he should be the head of the designing and drawing office.

"2. Subject to the control of this officer there should be a chief mechanical engineer, holding a civilian appointment, who should be in charge of and responsible for manufacture in all its branches. His subordinates, also civilians, should take charge of the various departments."

I learn with regret that the Secretary of State for War is making the whole system more military than ever. In the end it will be more expensive and not more effective than the condemned system. A military superintendent of ordnance factories has been appointed at a salary of £1,800 a year, with two military assistants, one at £700 a year and the other at £500 a year, with a large staff of clerks and writers. This military superintendent is not subject to parliamentary control (except for finance), as the office of Surveyor-General of Ordnance has been abolished. He is responsible to the military heads at the War Office. But the chief mechanical engineer, who should be in charge of and responsible for manufacture, has not been appointed, so that the newly appointed superintendent has not the effective assistance which would warrant the nation in having confidence in the department. This want of confidence is assisted by these repeated failures, not only in the material and design of our guns, but by faulty mechanical details. Let me give one example. A gun was ordered from one department and a Vavasseur carriage for it from another. The size and weight of gun were given, so that the carriage could be properly designed. When the two were brought together it was found that the gun was 5 tons heavier than had been stated, and before the carriage could be made to work it had to be altered at a cost of about £500. It is a minor detail, but one is anxious to know to what account this £500 was charged, as I feel sure the Treasury would not grant an extra payment for it. The Surveyor-General of Ordnance was accountable to Parliament for the spending of £8,000,000. The Financial Secretary to the War Office stated on the 1st of February that in appointing a member of Parliament to the post it was considered of no importance whether he happened to know the breech of a gun from the muzzle or not. But whose fault was that? I think a grave error has been committed in abolishing the office, thereby replacing military for parliamentary control.

SHIPBUILDING NOTES.

On the 13th inst. there was successfully launched from Messrs. Robert Thompson & Sons' Southwick yard, Sunderland, a steel screw steamer for the Nippon Yusen Kaisha Steamship Company, of Tokio, Japan. The following are her dimensions: Length, 331½ft.; breadth, 42ft.; depth, 28¾ft. She is built to class 100 A1 at Lloyd's, under special survey. The vessel has cellular double bottom for water ballast, six bulkheads, four large hatchways, with cargo ports, four horizontal steam winches and donkey boiler, Clark, Chapman, Parsons, & Co.'s patent windlass and steam steering gear, and large house on deck aft for captain and passengers, protected by a neat cape covering the stern. The bridge amidships is 70ft. long, for the accommodation of officers and engineers, and a large topgallant forecastle is provided for the crew. The engines are by Mr. John Dickinson, Monkwearmouth, and will indicate about 1400 h.p., and be capable of driving her 10½ knots. She has extra large boilers.

Messrs. Raylton, Dixon, & Co., of Middlesbrough, recently launched a very handsome screw steamer, built to the order of Messrs. Rathbone Brothers & Co., of Liverpool, for their Star Line of Calcutta steamers. The vessel is 352ft. long, and has a dead weight capacity of 4500 tons. She is beautifully fitted up for thirty six first class passengers, and electric light is used throughout.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION OF GREAT BRITAIN.—Saturday, 25th February, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

PHYSICAL SOCIETY.—Saturday, 25th February, 3 p.m. Note on "The Efficiency of Incandescent Lamps with Direct and Alternate Currents," by Professors W. E. Ayrton, F.R.S., and J. Perry, F.R.S.; "Observations on the Height and Length of Ocean Waves," by the Hon. Ralph Abercrombie; "Experiments on Electrolysis," by Mr. W. W. Haldane Gee; and "On the Temperature at which Nickel Begins to Suddenly Lose its Magnetic Properties," by Mr. Herbert Tomlinson.

NEXT WEEK.

CLEVELAND INSTITUTION OF ENGINEERS.—Monday, 27th February, 7-30 p.m. Ordinary meeting. Paper to be read on "The Working of the New Patent Law," by G. J. Clarkson, F.I.P.A., Stockton.

SOCIETY OF ARTS.—Monday, 27th February, 8 p.m. Cantor lecture on "The Modern Microscope," by Mr. John Mayall, jun.—Wednesday, 29th February, 8 p.m. Ordinary meeting. Discussion on Mr. Swire Smith's paper on "The Technical Education Bill."

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 28th February, 8 p.m. Ordinary meeting. Papers to be read on "Manganese in its Application to Metallurgy," and "Some Novel Properties of Iron and Manganese," by Mr. R. A. Hadfield, Assoc.M.Inst.C.E.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—Wednesday, 29th February, 7 p.m. Paper to be read on "Our National Defences," by Mr. William C. Street, A.R.I.B.A.

ARCHITECTURAL ASSOCIATION.—Friday, 2nd March, 7-30 p.m. Ordinary meeting. Paper to be read by Mr. F. M. Simpson.

GEOLOGISTS' ASSOCIATION.—Friday, 2nd March 8 p.m. Ordinary meeting.

ROYAL INSTITUTION OF GREAT BRITAIN.—Friday, 2nd March, 9 p.m. Lecture on "Poisons and Poisoning," by Dr. C. Meymott Tidy.

JUNIOR ENGINEERING SOCIETY.—Friday, 2nd March, 7-45 p.m. Paper to be read on "Practical Electro-plating with Various Metals," by Mr. F. N. Lewis, Stud.Inst.C.E.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 2nd March. 3 p.m. Paper to be read on "The Native Army of Bengal: its Constitution, Organisation, Equipment, and Interior Economy," by Major-General J. J. H. Gordon, C.B.

PRICES CURRENT, 23RD FEBRUARY.

Quotations at per ton, unless otherwise specified.

„ English Ingots	162	0	0	„	163	0	0

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER:—Chili bars have been sold rather freely at from £77. 12s. 6d. to £78. 5s. per ton for sharp cash parcels, and the market appears to be steady thereat. Manufactured—quotations are unchanged; but new business is scarce as yet.

TIN continues to be well held, and quotations have ruled during the past week from £166 to £167 per ton.

LEAD slightly weaker.

SPELTER.—The demand is easier, and prices a trifle lower; but a recovery is looked for.

MR. HENRY FAIJI, M.Inst.C.E., has removed his offices from No. 4 to No. 2, Great Queen-street, Westminster.

MR. B. H. THWAITE, Assoc.M.Inst.C.E., has arranged to read a paper on "Mill Engines," before the Yorkshire College Textile Society, on Tuesday next, the 28th inst.

MESSRS. WALTER T. GLOVER & Co., of Salford, have taken into their service Mr. Edward Whalley—late with Messrs. Thomas Unsworth & Co.—to superintend work connected with winding, twisting, laying, cabling, and balling, with which he has had a large experience.

THE Frictionless Engine Packing Company (Messrs. Small and Parkes), late of 27, Exchange Buildings, St. Mary's Gate, Manchester, have removed their works and offices to Cable Mills, Glasshouse-street, Oldham Road, Manchester. This removal has been rendered necessary on account of their late works at Wilmslow being too small to meet the demands of their present business.

HOME INDUSTRIES.

MANCHESTER, 23rd February, 1888.

The Engineering Trades.—Nothing of great importance has occurred since our last report. Stationary engine builders remain fairly employed, but at very low rates; with some exceptions the same remark applies to millwrights. There is not quite so much being done in the Burnley district, and the weaving sheds being built are not likely to be followed by others at present. There are ominous signs that the supply of cloth has now overreached the demand, and it is not likely that any extensions of weaving power will take place. Machine tool makers are obtaining more orders, and their prospects are gradually improving. The old established firm of Wm. Collier & Co., of Manchester, is to be offered for sale by auction as a going concern in the course of a few days. Boiler makers continue to be well employed, and find work plentiful. This business is probably in a more prosperous condition than any other branch of engineering, and does not appear to suffer at all by the depressed state of trade. Machine makers are also well employed, and almost without exception continue to find orders. The prospects of this trade would be very good, if it were not for the unreasonable competition to which we referred a week or two since. The constructional iron work makers have not much work on hand. An instance of the present cutting of prices is given in the quotation accepted for a number of cast iron gutters employed in the erection of a weaving shed in the East Lancashire district. The gutters are of the usual section, and the contractor had in delivering them a charge of 5s. a ton for carriage; the contract also included the erection. The accepted price was 4s. 10d. per cwt., a rate equal to about 3s. 6d. or 3s. 8d. at works for the castings, without painting.

The Iron Trade.—With the lower prices now ruling in the pig iron market, the amount of buying in this district has fallen off very considerably. During the rise most consumers bought very freely, and the result is that they are well supplied with material. Makers' prices of local and hematite irons are higher, in proportion, than the quotations for Scotch and Cleveland iron; hematites being specially firm, owing probably to the large contracts entered into during this month. There are, however, low rates being given for all classes of iron, mainly from middlemen, who are doing the bulk of the business transacted. Bar iron is also being sold in very small quantities, although makers' prices are fully maintained. The competition of second hand lots in this department is also much felt. Steel bars and plates fully maintain the recent advance, and are finding a fair sale.

The Ribble Scheme.—It has now been decided by the Preston Town Council that the engineer to be called in to report on the above scheme shall be Mr. Jas. Abernethy, M.Inst.C.E. The terms of the reference are very large, and amount to asking for a report on the whole scheme. With reference to the dock proper, there is no difference of opinion, the crux of the question being the dredging of the channel. There is a long length to dredge; but we believe it is a fact that so far as this has been carried out, the advantage to the channel has been very marked, the additional scour having greatly improved it up to and behind the actual place where operations are being carried on. Mr. Abernethy's great experience in works of this kind will enable him to form conclusions which will be generally accepted.

LONDON, 23rd February, 1888.

The Money Market.—The money market gained a little more life during the past week, but this is gradually ebbing away again. The inanition of the stock markets is very marked, and the Stock Exchange is waiting upon the news from San Remo. Mining shares move up and down in a weak and uncertain manner, with an inclination to fall away. The only class of shares which show a tendency to rise, and maintain the rise, are those of the Indian gold companies. A little more interest is now being shown in, and energy expended upon, these gold companies, the one movement encouraging the other, so that both in the prices of the shares and the character of the work done in the mines there is a marked improvement. Of new issues the most important is that of the Naval Construction and Armaments Company.

Companies.—Since our last report the following new companies have been registered: Joshua Smith, Limited, with a capital of £40,000, to carry on business as cotton spinners, &c.; Liddiard & Wordley, Limited, with a capital of £10,000, to carry on business as ironmongers; the Carbonising Syndicate, Limited, with a capital of £3,100, to carry on the business of carbonisers of sugar scum, &c.; F. W. Oliver & Co., Limited, with a capital of £30,000, to acquire a business carried on in decorative glass, and patents in connection with the same; the Norwegian Zinc Company, Limited, with a capital of £56,000, to acquire a zinc mine in the neighbourhood of Sandeforth, Stavanger, Norway; the Aberthaw Pebble Lime Company, Limited, with a capital of £10,000; Tregeale Tin Mining Company, Limited, with a capital of £20,000; Bryceson Brothers, Limited, with a capital of £11,000, to purchase the business of organ builders and wood working machinists carried on at Charlton Works, Islington; Tower Fibre Dressing Company, Limited, with a capital of £2,000; Eastern Oregon Gold Mining Company, Limited, with a capital of £250,000; St. Neot's Paper Mill Company, Limited, with a capital of £30,000; Australian Broken Hill Consols, Limited, with a capital of £500,000. The prospectus of the Naval Construction and Armaments Company, Limited, a new undertaking with a capital of £600,000, states that the principal objects of the company are to build ships of war in England and Spain, and to develop new inventions connected with coast defence. Arrangements have been made for the purchase of a shipbuilding yard and engine works at Barrow, and it is proposed to erect as a branch establishment a shipbuilding yard in Spain, with a view to obtain a part of the orders from the Spanish Government for men-of-war. Our Madrid correspondent, it will be remembered, explained some time ago that preference would be given to local yards, and advocated the association of English shipbuilding firms with Spanish works. In the present instance Messrs. C. de Murrieta & Co., of Bilbao, will co-operate with the company.

Copper.—The demand has been poor for all descriptions of copper except Chili bars, and the rates have been considerably out of proportion to the price of the latter. Purchases are being restricted, and quantities of old copper are being used. At the same time larger supplies are coming to hand from the mines which have not contracted with the syndicate, so that it is doubtful whether the artificial rates can be kept up.

Textiles.—The Colonial wool market has been somewhat weaker since our last report, and, generally speaking, rates are on a par with those ruling at the close of the last series of sales. Woolled sheepskin sales will be held on the 9th of March.

Produce.—The sugar market continues depressed, and buyers hold back; but owing to the deficiency in the beet harvest it is probable that the present low rates will not last. Owing to increased supplies of coffee having come into the market, but little progress has been made, and the higher prices obtained at the beginning of last week could not be maintained.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 12th February, amounted to £1,118,071 on 15,831½ miles, as compared with £1,089,973 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 122¾ miles or 0·7 per cent., and in the receipts of 2·5 per cent.

The Navy.—An official trial has been made of the engines of the composite ship "Buzzard," with satisfactory results. On a previous run in the Medway the port engine broke down. Trials are in course of progress at Portsmouth with the "Severn," which has been fitted with the torpedo launching gear of Captain May, R.N., which we briefly described in our issue of the 18th October, 1886. By this appliance the torpedo is projected under water, while the vessel is steaming at a high speed. It is announced that the forthcoming programme of the Admiralty will include the construction of three new men-of-war. One of these will be the "Barracouta," the first of a new type of steel sloops designed by Mr. W. H. White, which will have a displacement of 1580 tons. There will also be a new sloop of the "Buzzard" type of 1040 tons displacement, and with engines of 1200 h.p.; and a fast gunboat of the "Bird" type of 805 tons displacement and 1200 h.p.

Our Big Guns.—We re-produce this week Mr. Carbutt's recent letter to *The Times* on the bursting of a 10in. gun while under proof at Woolwich, to which we referred on page 142, and since then the Secretary of State for War has been questioned on the subject. The official reply is that the cause of the failure is now under investigation by the Ordnance Committee. The gun had been designed at the Royal Gun Factory, but the design was modified during manufacture, the gun being chase hooped and lined, in accordance with the proposal of the Elswick Ordnance Company, who made it. Mr. Stanhope considers that a marked distinction should be drawn between failures at proof and failures on service. He fears that severe criticism in Parliament might produce a tendency to pass into actual service guns which had not been scrupulously tested.

Canals.—A conference will be held by the Society of Arts in May on the subject of canals and inland navigation. Papers will be received on the history of canal and river navigation, canal engineering, uniformity of gauges, systems of haulage, methods of construction, locks, and hydraulic and other apparatus for raising and lowering barges.

GLASGOW, 23rd February, 1888.

Railway Traffic.—Last week the railway traffic showed a conspicuous advance. In the goods traffic of the Caledonian and of the North British Railways the increase was respectively £2,628 and £3,032. These figures, coupled with the recent traffic returns of the same railways, are satisfactory evidence of a greater movement of commodities.

Iron.—Two furnaces were blown in last week, though the price of pig iron is not encouraging, the extremely low figure of 38s. 11d. per ton having been touched last week.

Steel.—The steel makers are all much occupied at present, new furnaces being in course of erection at some of the largest works. For some time past users of large quantities of steel have been finding it extremely difficult to procure the quantities required in the necessary time limits. Existing steel producing plant is strained to its utmost extent.

Coal.—The depression in the iron trade is perhaps even more seriously affecting coal. The pit-head heaps are accumulating, and work is far from continuous. Prices, both for steam coal and for shipping coal, are low; the former is quoted at 7s. 3d. to 7s. 6d., and the latter at 5s. 6d., delivered at the terminus.—The Admiralty are reported to have asked four of the Slammanan coal firms to send estimates for five hundred tons of steam coal. This quantity is required for the preliminary trials of Scotch coal, upon which the Admiralty had determined before Lord Charles Beresford left office.

Shipping.—Freights are still firm, especially to India and the East generally. Home freights from Eastern ports are also being maintained, and in some cases advanced considerably.

Porterage Rates by Clyde Shipping Lines.—The Allan Line, the Anchor Line, the State Line, and Messrs. Donaldson Brothers have been approached by the importers of flour by their steamers, upon the subject of the charge for master porterage. The usage has been for many years for the ship's agents to discharge the duties, and levy the rates for master porterage. These rates have been fixed for some time at 1s., less 7½ per cent. per ton. The flour importers offered to pay 10d. per ton, but no more, the difference being 1⅛d. per ton. The shipping companies offered to submit the question to arbitration; but this proposal was rejected, and the companies have now given notice that they will not permit anyone except their own agents to discharge the duties of master porterage for goods arriving by their steamers, and that they will adhere to the current rates. The question is a serious one, since the claiming of such a right by shipping companies might conceivably lead to abuses.

Cotton Spinning in Glasgow.—The directors of the Glasgow Cotton Spinning Company have just issued their report for the quarter ending 31st January. They announce a dividend of 3s. per share for the quarter, being at the rate of 10 per cent.; the profits having been £1,770. This is an evidence of improvement in the cotton spinning trade, which has been in a very depressed condition in this district for some time.

Naval Architecture.—Professor Jenkin, who occupies the Chair of Naval Architecture in the University of Glasgow, delivered the first of a course of evening lectures on "The Strength of Ships," on Thursday last. The lectures are to be delivered in the new class rooms, provided for the Chair of Naval Architecture by Sir William Pearce, Bart. The building materials were removed from the old college buildings, in the High-street, on their demolition by the North British Railway Company.

The Money Market.—On Monday evening, Mr. Charles Gairdner, manager of the Union Bank, and President of the Economic Section of the Philosophical Society, delivered an address upon "The Constitution and Course of the Money Market." He discussed the question of the appreciation of gold, argued against bimetallism, and described the effect of the expansion of credit upon the monetary requirements of commercial nations.

(From our own Correspondents.)

LIVERPOOL, 22nd February, 1888.

The Overhead Railway.—There is every probability of this work being carried out at an early date, for there will be practically no opposition to the Bill now before Parliament for an extension of time and for leave to transfer the powers to a company.

The Vessels Sunk in the Mersey.—The operations of blowing up the "Baroda," which was sunk at the entrance to one of the docks about two months ago, have only just been completed, the work being much more difficult and costly than was anticipated. Preparations are now being made for blowing up the "Rollas," recently sunk at the entrance to the Duke's Dock. It was this vessel, when under the name of the "Murillo," which ran into the "Northfleet," some years ago, and caused the frightful disaster in the English Channel. It seems remarkable that a rich body like the Mersey Docks and Harbour Board should not have efficient apparatus for raising wrecks, instead of either having to pay enormous sums to contractors to undertake the work, or to resort to the dangerous and inconvenient method of blowing them up. Over £15,000 was paid for raising the "Locksley Hall," the actual cost to the contractors not exceeding £2,000, and several thousands will be expended in blowing up the above two vessels.

SHEFFIELD, 22nd February, 1888.

Iron and Steel.—The condition of local trade is still satisfactory. Makers and merchants have done a good business during the past few days in iron and steel. Bessemer and crucible are in great request, and although there have been fluctuations, yet on the whole the material has maintained its price. The strike at the works of Messrs. Charles Cammell & Co., at Workington, has fortunately terminated, the manager's conditions being accepted by the men. It is fortunate that the dispute is over, for the output of steel rails at Workington is enormous, especially on foreign account. At two or three of the large Sheffield works considerable attention is being given just now to improvement in plates and projectiles; but the firms that have put down plant for the manufacture of ordnance at great cost, are beginning to think that the orders they understood they were to obtain from the Government are coming in

Digitized by Google

very slowly. Sheffield is just now doing a satisfactory trade in railway material, not only in rails on foreign and colonial demand, but in axles, railway springs, and tyres. The waggon builders are also busy; and makers of shipbuilding material, engineers, and iron founders are very well employed.

LIGHTER BRANCHES.—The continued frost has caused a great demand for skates. In cutlery there is no complaint of depressed trade. America is not ordering so largely; but the home demand for best descriptions of table cutlery is increasing, in spite of the high price of ivory. The Continent is taking a vast quantity of table and pocket cutlery, as well as surgical instruments; and there is both in Germany and Austria, and also in Russia, a growing inquiry for Sheffield manufactures of good quality. The electro-platers have not been so well off for orders for some months past. This branch of Sheffield trade has expanded enormously during the past ten years, and some of the best known local firms send their work in silver and electro-plate to all parts of the world.

COAL.—At a number of the collieries the men are working five and six days a week. The call for coal of all kinds is extensive; but particularly for manufacturing and shipping, and for the London market. The colliers have abandoned their agitation for an advance of wages and are wisely continuing their work at the old rates.

LEEDS, 22ND FEBRUARY, 1888.

THE HEAVY INDUSTRIES.—A steady trade is being done in manufactured iron. The output of Bessemer steel is satisfactorily increasing, and prices keep firm. The engine builders have lately obtained some good orders for locomotives and engines for tramway work. All descriptions of railway material are more eagerly called for, and tyres and axles are being turned out rapidly for immediate needs. The heavy snowstorms have done damage to permanent ways and rolling stock, and a good deal of material has been ordered for renewals. Leeds is developing a trade with China, whither she is sending engines and plant for various purposes. A better Colonial trade is also being done. For hydraulic machinery, boilers, and shipbuilding there is an extensive demand; indeed, it is difficult to say what particular branch of local industry is not in a more prosperous condition at present than it was at the end of the year. For engineers' tools there is an extending market; and cut nails are selling more readily week by week. In the lighter branches of Leeds trade there is not much change to report, except that the severe weather has greatly increased the demand for woollens and warm clothing of every description.

BIRMINGHAM, 22ND FEBRUARY, 1888.

THE IRON TRADE.—This trade is fairly busy, especially in the finished branches. The demand for pig iron is rather quiet; unmarked bars are most in demand, at about £5 to £5. 10s., and sheets for galvanising purposes go off freely at £6. 5s. and upwards for singles, and £6. 15s. to £7 for doubles. The price of galvanised sheets at the ports is £12. 10s. to £13 for 24 gauge. The Australian Colonies are taking an increased quantity of this class of goods, and they also find ready sale in other Colonial markets, especially those of the southern hemisphere. A movement is in progress towards the replacement of sheet iron by steel for galvanisers' use, and this alteration will have an important influence upon the relative position of the two metals in South Staffordshire. Already a considerable quantity of sheets are employed where formerly iron was used. In the netting departments of the galvanising trade there is more being done, and in such branches as bucket, bath, and pail making, there is a fair activity. Business is rather restricted in the pig iron market, Northampton and Derby irons being in most demand at 40s. to 41s. Staffordshire hot blast all-mine is selling at 52s. 6d., and second qualities at about 40s. Final arrangements have been made for re-starting the Bromford Iron Works, which were closed some time ago in consequence of the failure of Messrs. John Dawes & Sons. About twenty-two puddling furnaces will be re-lighted this week, and a staff of workmen numbering one hundred are now engaged in preparing for the start.

LEICESTER, 22ND FEBRUARY, 1888.

HOSIERY TRADE.—Business in this industry has not developed to the extent anticipated at the beginning of January, and trade generally is not so active as it usually is in the middle of February. There are more buyers moving amongst the houses, and it is hoped that good orders will result from their visits. Cashmere goods are fairly in demand, and some houses are busy with contracts for cottons and merinos. Competition is extremely keen, and prices quoted are at very small profits.

WOOL SPINNING AND YARN TRADES.—The condition of the wool trade continues to be very unsatisfactory, and is full of uncertainty. The London sales of Colonial wool increased prices somewhat; but this has not affected the local market to any extent, and prices are much as they have been since the opening of the year. Growers and country dealers, whilst not anxious to dispose of their generally small holdings, are now more commonly disposed to make a reduction to effect a sale. Consumers apparently have very little faith in the stability of the present quotations, and buy but very sparingly, usually for immediate requirements. Staplers therefore are not moving, and the turnover is light all round. The spinners are not in a very good position; their orders are scant, and there is much more going into stock to keep the machinery employed than is satisfactory. Buyers hold out for lower quotations, and to obtain orders business has to be done with a very small margin of profit. Yarn merchants are not doing very much.

NORTH STAFFORDSHIRE, 22ND FEBRUARY, 1888.

THE COAL AND IRON TRADES.—The retrogressive movement which has occurred during the past four or five weeks still continues, and prices have fallen back to their old level. On the whole the volume of trade has somewhat increased. The critical time is approaching which will determine the price of pig iron. If makers were only strong enough to hold off the market until the third week in March is passed, consumers would be forced to pay higher prices for their pigs; but it is becoming more apparent that the reverse will be the case, and probably the early part of next month will see many contracts booked for delivery to June at little, if any, above 1887 prices. Earl Granville has blown in another furnace at his Shelton iron works this week. The severe weather is exercising a beneficent influence upon the course of the coal trade, and those collieries producing good fuel for domestic consumption are unable to meet the demand upon them; but prices are low, and not very remunerative.

SOUTH WALES, 22ND FEBRUARY, 1888.

NEW PATENT FUEL WORKS.—The Crown Patent Fuel Company, promoted by Mr. Samuel Butler, is about to erect extensive works near the Old Sea Lock at Cardiff, for the manufacture of patent fuel. It is stated to be the intention of Mr. Butler to commence operations with an output of 100 tons per day, although the plant will be designed to turn out twice this quantity.—It is announced that a new tin plate works and a pottery are shortly to be started at Llanelly, in connection with both of which several influential names are mentioned.

SWANSEA HARBOUR TRUST.—Mr. John Dixon, of Clifton, Bristol, formerly the general manager of the Avonmouth and Sharpness Docks, has been chosen out of a large number of candidates to fill the vacant superintendentship of the harbour. The salary is £800 per annum.

THE "SUNBEAM" INCANDESCENT LAMP.—Messrs. Walker and Olliver, of Cardiff, are introducing this electric lamp into South Wales, and have it already at work in several collieries. This lamp is simply a large glow lamp, in which a carbon thread takes the place of the thin filament used in the small lamps. As the lamp is made to give from 200 to 1500 c.p., it is intended to take the place of the arc lamp, which in some of its forms has so many drawbacks. The "Sunbeam" can be worked upon any existing electric light circuit, and, of course, requires no attention except when it has to be renewed.

BARROW-IN-FURNESS, 22ND FEBRUARY, 1888.

IRON AND STEEL.—There is a steady trade in hematite pig iron, and orders are offering very freely both for pig iron and steel. Prices of the former are steady at 43s. 6d. to 45s. per ton net f.o.b. for Bessemer samples, although hematite warrants have changed hands at 42s. to 42s. 6d. per ton. Stocks in makers' hands are small, and are not increasing. There is a brisk trade in all classes of steel, and the market for rails is much better than it has been, prices remaining steady at £4 per ton net f.o.b. for heavy sections. The demand for ship building material is brisk. There is a large output of both plates and angles, and arrangements are in progress to further increase the production on local as well as on general account. There is a good business being done in shipbuilding material, and shipbuilders themselves are also much better placed for business than they have been for some time. There is also a growing activity both in boiler making and engineering, and good orders are expected both on marine and general account.

MIDDLESBROUGH, 22ND FEBRUARY, 1888.

TEES CONSERVANCY RETURNS.—The revenue of the Tees Conservancy Commission for January shows a total receipt for dues on ships and goods of £5,330. 16s. 8d., against £4,618. 5s. 4d. in the similar month last year, being an increase of £712. 11s. 4d. On the total revenue for the first quarter of the financial year just ended there has been an increase of £1,305. 2s. Both Middlesbrough and Stockton take part in the improvement, but chiefly the former.

PIG IRON.—The Cleveland pig iron market remains quiet but steady, and it is showing signs of reaction in favour of an advance. Indeed, the general condition of business certainly warrants such an expectation, and had it not been for some late reckless speculation, there is but little doubt the advance would have been an accomplished fact. The average price for No. 3 G.M.B. is 31s. 6d. per ton for early, and 31s. 9d. for April-June delivery. Warrants are 31s. 3d. per ton cash for Connal's No. 3 G.M.B., and 42s. 6d. nominally for Connal's hematite, mixed numbers. It is a favourable sign that Connal's stores have been decreasing of late at the rate of some 6000 tons per week on the average.

IRON AND STEEL.—Finished iron has quieted down, although some report that inquiries are as numerous as ever. Still there is not the same pressure, and the inquirers are content to wait for more favourable terms. Plates £5, angles £4. 12s. 6d., bars £4. 17s. 6d., engineering angles £5, girder plates £5. 5s. on trucks at works, cash, prompt delivery, less the usual discount. Puddled bars £3. 2s. 6d. net. In steel there is the same pressure for steel plates, the ship yards not being so well supplied as they would like. Rails, however, are not so much in demand, and 5s. per ton less has been taken to secure an order. Ship plates are £6. 15s. and ship angles £6. 10s. on trucks at works, less the usual discount. Rails are £4 to £4. 5s., ordinary sizes.

SUNDERLAND, 22ND FEBRUARY, 1888.

SHIPBUILDING.—Work in a number of the shipbuilding yards is being retarded by the slow delivery of material from the steel makers. Messrs. Bartram, Haswell, & Co., South Docks, have only one vessel visible in their yard, but have other work which will be proceeded with shortly. The Sunderland Shipbuilding Company, Limited, are more fortunate, having all their berths occupied. Messrs. William Doxford & Sons, Pallion, have three vessels in progress of construction, and are making preparations for laying down a fourth. Messrs. Robert Thompson & Sons, Southwick, are framing a steamer; Messrs. Short Brothers and Messrs. Joseph L. Thompson & Sons continue to have their yards fully occupied; Messrs. W. Pickersgill & Co., Southwick, have one steamer framing, and will shortly commence on the China river steamer; Messrs. J. Blumer and Co., North Docks, are rapidly completing the vessel on the stocks, and are also preparing the blocks for another steamer; Messrs. Osbourne, Graham, & Co., North Hylton, are making steady progress with the plating of their vessel.

MINOR INDUSTRIES.—The quarries and lime-kilns at Fulwell continue to be fully worked, but there is not so much animation at present in the sheet glass manufactories. The Hendon Plate Glass Works have resumed operation under the new management.

NEWCASTLE, 22ND FEBRUARY, 1888.

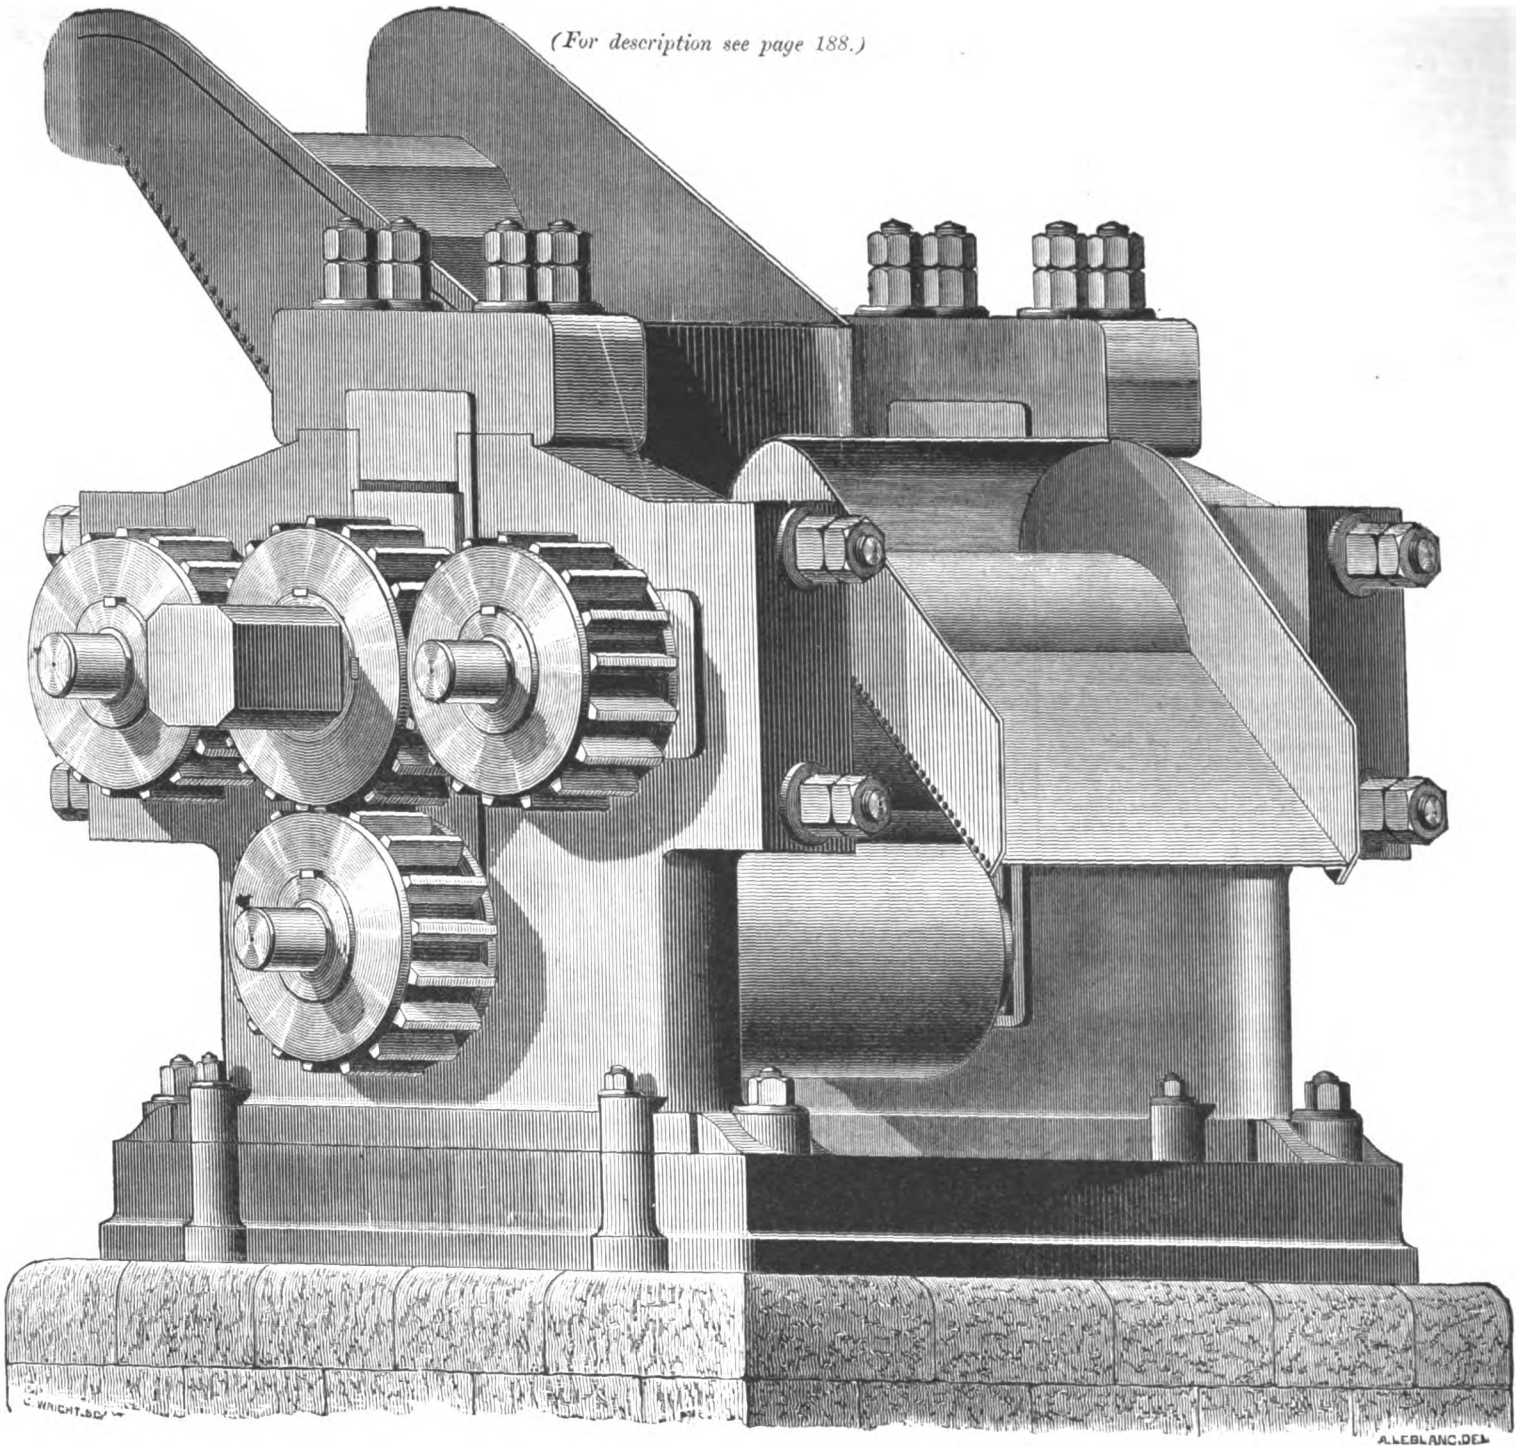
CHEMICALS.—There is a diminished demand for all kinds of chemicals, excepting for caustic soda, which is a special product of Messrs. Allhuson's works, Gateshead, and prices have shown a corresponding tendency to decline. The last named firm are utilising existing resources to the uttermost to satisfy the demand for caustic, and the new works, which are to be erected with a view to the extended manufacture of this commodity, will very shortly be proceeded with. The firm have this week temporarily stopped the manufacture of chloride of lime, as the stock at present on hand is somewhat heavy. The stoppage is likely to continue for a month. Trade is dull at most of the other factories on the river.

CEMENT.—The demand for cement, both on account of home requirements and for export, is still satisfactory, and at all the works in the district the present output is quite up to the standard of the busiest periods in the past.

COPPER.—Shipments of product from the Tharsis Copper Company's works at Hebburn have been unusually light since the beginning of the month, but this circumstance has not caused any diminution of activity in the manufacturing departments. Stocks are consequently pretty heavy, but will no doubt soon be reduced to the ordinary level.

LEAD.—There is comparatively little being done in the manufacture of sheet lead, but in other departments of this industry business is fairly good.

PAINTS, COMPOSITIONS, &c.—The different paint manufacturing establishments in the district are very busy at present, new outlets for consumption having arisen since the opening of the year. Messrs. S. T. Taylor & Sons have several important orders for their patent boiler covering composition in course of execution, and their works are now quite busy. Messrs. M. Holzapfel & Co., manufacturers of patent anti-fouling composition for ships' bottoms, are experiencing so large a demand for their specialty, that they are finding it necessary to increase their productive resources. They are adding a large building to their present manufacturing premises on the South Shore Road, Gateshead, and in the course of a few weeks will be able to increase their output to an extent which it is hoped will be sufficient to meet even the larger demand which is anticipated.



BELFAST, 22ND FEBRUARY, 1888.

SHIPBUILDING.—Shipyards still continue to be well employed, and new orders are regularly booked. Mr. C. J. Biggar, of Londonderry, has secured an order from Messrs. A. A. Laird & Co., Glasgow, for a steel screw steamer of 600 tons, for their cross-channel passenger trade; this yard has in addition two large vessels on the stocks, which, with some good repair work in hand, will keep them busy for some time. The s.s. "Oceana," built by Messrs. Harland & Wolff, for the Peninsular and Oriental Company, left Belfast on the 18th inst. in tow for Liverpool. She presented a very fine appearance when finished, and as she is the largest vessel yet built in Belfast so she will be one of the largest in the P. & O. fleet. Her sister ship, the "Arcadia," will be ready in a few weeks. Mr. De Cobain, M.P. for one of the Belfast divisions, is about to introduce a Bill into the House of Commons making weekly wages compulsory throughout Ireland, which, if passed, would specially affect the shipbuilding trade. Engineers and boiler makers are fairly well employed on past orders, but the amount of new orders is not so satisfactory.

OUR FOREIGN TRADE.

THE comparison of what business we are doing in foreign markets, with the progress made by Germany, is usually not looked upon as a matter calculated to give unbounded satisfaction to our own manufacturers, and it is therefore a refreshing novelty to come across a report on this subject in which optimistic views are held with respect to our position. Such, however, are the views of Mr. R. Giffen, who, in a report prepared for the Board of Trade, which it is intended shortly to present to Parliament with detailed tables, maintains that the popular impression given by reports from our Consuls in foreign countries that German trade is gaining ground everywhere at the expense of English trade, is largely due to the fact that from British possessions we receive no consular reports. He says that the reiteration of particular facts from many little places as to German competition, while the larger trades are not reported on, produces the illusion that the trade of the United Kingdom is giving way at every point, whereas the actual facts are entirely different, and that though the particular facts stated are in all cases important in their own places, the inference as to the general course which English export trade is taking is too hasty. This sounds somewhat like special pleading; and therefore Mr. Giffen supports his theory by means of figures, of which he is admitted to be a skilful manipulator. In undertaking the inquiry into the subject, the country to which most attention was given was Germany; but France and the United States, as formidable manufacturing rivals, have also been taken into consideration. Comparing the periods 1875-77 and 1884-85, our imports were the same, viz., £381,000,000; those of Germany fell from £241,000,000 to £229,000,000; those of France rose from £185,000,000 to £203,000,000; and those of the United States from £100,000,000 to £130,000,000. The exports in the same periods were respectively: From England, £207,000,000 and £223,000,000; from Germany, £130,000,000 and £151,000,000; from France, £145,000,000 and £126,000,000, and from the United States £112,000,000 and £151,000,000. Commenting on these statistics Mr. Giffen says, "Such as they are, these figures do not by any means suggest that German trade generally has been developing enormously in comparison with the development of the trade of the United Kingdom, while the increase in French imports is more than set off from the point of view of the present inquiry by the exports. The increase in the trade of the United States is great and conspicuous, but apparently the trade is not of a kind which comes into competition with that of the United Kingdom, and, as far as the exports are concerned, is largely an increase to the United Kingdom itself." This looks rather as if Mr. Giffen had set about his task with the preconceived idea of proving that our foreign trade is progressing as satisfactorily as can be desired; whereas it is evident that this is not so, for the rate of increase in the exports of Germany during this period is double ours, and that of the United States four times ours. We are therefore not making the headway that we should, and this point is well worthy of notice. At the same time it is undoubtedly the case that outside Europe our trade is predominant, and it is also pointed out, with justice, that the countries in whose trade the imports from the United Kingdom preponderate are the largest traders. The exports of the United Kingdom to each of our three great competitors also much exceed the exports from each of any two of these competitors to the third. Taking the two periods already referred to, the proportion of imports from the United Kingdom to European countries, Egypt, the United States, Argentine Republic, Uruguay and Chili, China, Japan, and British possesions is given, and Mr. Giffen in this connection congratulates this country on the fact that the proportion of our business has in no important case sensibly diminished, while the amount of the business, owing to the general increase of the imports of the countries named, must have largely increased. This is no doubt true; but still the fact remains that there is a decrease in the proportionate rate of imports from Great Britain, varying from 1 to 10 per cent., and that in no case is there an increase in our proportion, whereas German trade with the same countries shows an increase all round. Mr. Giffen's opinion is rosy, and his general conclusion is that Germany has not been gaining in common markets of late years at the expense of English trade, that her gains have been of a special character, and that our predominance in the great common markets remains substantially what it was ten years ago.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 3d. for each additional line; one inch and over at 8s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Industries:

FRIDAY, 24TH FEBRUARY, 1888.

THE PROTECTIVE POLICY OF ITALY AND BRITISH TRADE.

AT a time when many of our foreign markets are being restricted or partly closed against us, by the imposition of heavier protective duties, it is pleasing to learn that the new Italian tariff will conduce rather to the extension of our trade with Italy than to its contraction. That such a result must follow, it is not difficult to show, at least in the cases of the iron and coal trades. The Italians are resolved to have their own iron industries, and of late years the Government has encouraged the erection of new works, and has given active aid in developing them. Hitherto these works have been designed with a view chiefly to prepare the finished products, that is, manufactured iron and steel. The plan followed has been to import the half wrought material, leaving the development of this branch of the industry for a later period. We cannot contemplate the actual position of the native industry without being struck with the progress already made. In various parts of the country, and always in situations favourable to their growth, important works have been established, and in every case they exist in a vigorous and flourishing state. To foster their growth, the Government has applied the system of protection, imposing heavier duties as the young native industry grew stronger, till now it has decreed a prohibitive tariff, manifestly designed to crush out the import trade in the finished products of iron and steel. In many cases the imposts have been doubled. Bars and rods of more than 7mm. diam. or side are henceforth to be taxed 65 lire per ton; those between 5mm. and 7mm., 75 lire; while for those below 5mm. the rate is 90 lire. Rolled wire will thus be subject to a duty of 75 lire, or £3 a ton, so that the duty and freight will together amount to more than the cost of production. For plates of 4mm. and over in thickness, the new duty is 70 lire per ton; between 4mm. and 1½mm., 100 lire; and below 1½mm., 120 lire. Even these high rates will, through a fine distinction in the official description, be increased by 10 lire for most classes of plates that do not strictly satisfy the conditions laid down for fine plates. Further, the duties on steel have been greatly augmented. For steel in bars, the new tariff imposes a rate as high as 120 lire. Obviously, these additional impositions must restrict the import trade in the materials of manufacture within very narrow limits. But the new protective policy goes further, and imposes fresh burdens upon manufactured goods. Thus, steel springs, for example, are made dutiable to the extent of 180 lire per ton, and this rate applies equally to heavy railway and to light carriage springs. So protected, Italian manufacturers may be expected to speedily find the means of adequately meeting the demands made upon them.

Of the import trade in finished iron and steel and manufactured goods, which is directly aimed at in the new tariff, the Germans have the largest share. Their exports of these classes of goods to Italy in the year 1887 amounted to 101,271 tons, exclusive of machinery, a quantity much larger than that which we sent thither. Bars and angles figure in this total for 33,754 tons, against the 17,825 tons tabulated in the Board of Trade returns as exported from this country. Of rails we sent a larger quantity, some 18,000 tons, against 13,000 tons from Germany; and we have the advantage also in the trade in plates, viz.: 13,128 tons, against 9715 tons. But we drop behind so rapidly in other classes of goods, that the total falls far short of the quantity attributed above to our rivals. In addition to the finished material and the manufactured goods which make up the foregoing total, the Germans exported to Italy 10,222 tons of half wrought iron and steel, that is, blooms, ingots, puddle bars, &c.; 14,153 tons of scrap; and 2991 tons of pig iron. We also sold to our Italian customers considerable quantities of half wrought materials and scrap; but the imperfect information afforded by the Board of Trade returns leaves us unable to draw a comparison in these particulars with the more complete, and therefore more useful, statistics collected by the German Customs Office. The defect has been partly remedied in the January issue of the returns; for we there find a fuller description of the trade with Italy than we have hitherto been given. From this issue we learn that in the first month of the current year our exports of scrap iron to Italy amounted to 8131 tons, while those of manufactured goods reached 6145 tons. The important point, however, in our argument is clearly set forth, viz., that while our trade with Italy is relatively small in the finished products of our iron works, our blast furnaces have been sustained by a rapidly growing demand, which reached last year the large total of 122,994 tons.

It is in this circumstance that our strength lies, and here we find the proof of the proposition with which we started, viz., that the new tariff will do us good service. The Germans are so heavily handicapped by the high rates of the St. Gothard Railway, as well as those of the Italian lines, that they cannot offer us, who have the great advantage of cheap sea carriage, any serious competition in the crude iron trade with Italy. This fact is clearly visible in the figures we have already quoted. Circumstances are so much in our favour that we are able to retain this trade against all rivals, and to continue to furnish the Italians with practically all the crude iron they need above what they themselves are capable of producing; and when their blast furnace industry has attained a degree of importance sufficient to justify the Government in excluding crude iron by the means now to be applied to the finished product, there will remain to us an immense and growing trade in coal, capable of affording us some compensation for the loss of the iron markets. Thus the prospect in the near future is cheering. Whatever contraction may result to the trade in finished iron and steel and manufactured goods—a loss that will be distributed among the German, British, Belgian, and French industries—a corresponding expansion must follow in the demand for the crude material, the whole of which increase will fall to our share. Therefore, great as our trade in pig iron now is, and rapidly as it has grown of late, we may reasonably hope to see it undergo further development in the course of the next few years, and this renewed vigour will be attributable to the protective measures which have occasioned so much alarm among our Continental rivals. As for the coal and coke trade, this obviously must increase with the capacity of the native industries. Already it has attained to colossal proportions, our exports to Italian ports in 1887 amounting to 3,186,854 tons, against only 77,823 tons from Germany. But the greater needs of the Italian works, due partly to natural growth and partly to the gradual extinction of the import

Digitized by Google

trade in iron goods through a prohibitive protective tariff, will insure a constant growth for many years to come. In this matter again we have the advantage of cheap over-sea transport, against which our rivals in the same trade will struggle in vain. In view of these favourable circumstances, existent and in prospect, it will be a safe prediction to assert that before the end of the current century Italy will have become our best customer for coal, a position hitherto held by France. Thus we can afford to look on complacently while the Italians labour to develop their iron industry, even if their method involve the application of the system of extreme protection, assured that whatever the consequences may be to other nations, to us they must be a cause of considerable gain for a time in iron, and for an indefinite period in coal.

PROFESSOR HUXLEY AS A CONTROVERSIALIST.

Professor Huxley is a born controversialist. His lusty strokes for Darwin in his fight with the critics of "The Origin of Species," confirmed a reputation which had already begun to be made. And from then till now he has never shrunk from a literary duel when the theory of natural selection has been called in question. It was only the other day that he ransacked the pages of the Jesuit fathers to prove that Mr. Mivart was at fault in his knowledge of the scientific teaching of his own church. His controversy with Mr. Herbert Spencer upon "Administrative Nihilism" is familiar to every student of the functions of the State. And recently he has made use of a famous phrase as the text of an essay upon the need for technical education, if we would keep our foothold in the international "struggle for existence."

In his recent paper Professor Huxley promulgates what he calls a programme, and in its first part he pipes to a gloomy enough tune. The rate of increase of the population alarms him. He finds ahead only intenser struggle, domestic and international, and nothing but an increasing accumulation of misery at one pole and wealth at the other. It would be a foolhardy experiment to interrogate Professor Huxley on the biological basis of his argument, yet the question is worth asking whether the rate of increase of population may not be expected to decrease as organic evolution goes on. Mr. Herbert Spencer's laws of multiplication mean nothing if they do not mean this. Professor Huxley might at least have given us this ray of hopefulness, for after all it is the quality of the race and not its quantity which is the important point. If by improving its quality we at the same time place the only effective check upon its excessive increase in numbers, a new hopefulness is infused into the minds of those who see no reason to doubt the general law of multiplication—the tendency of population to outrun subsistence—and yet believe in the folly of folding their hands in helpless hopelessness. It seems a pity that Professor Huxley, treating the question as he does in discursive and popular fashion, misses so large a modification of the bare law of increase, for the omission places his whole argument upon a distinctly inferior plane. Indeed, the omission of this important element involves him in an obviously inconsequent line of reasoning. He starts from the discredited assumption of Hobbes that the normal state of mankind is one of war, and he argues that the history of civilisation is the record of escape from this position. Yet he goes on to show that, instead of escaping from this struggle, we are ever becoming more deeply involved in it, and that so long as "reckless Istar, non-moral Nature" has the government of things, the struggle for existence must continually grow more intense. He sees nothing but catastrophe looming in the distance, for although he does not indicate the alternative, it is clear, unless there be some biological law which makes for preservation as powerfully as the tendency to reproduction makes for destruction, that there can be nothing ahead but catastrophe. At this point it was surely Professor Huxley's plain business to examine Spencer's laws of multiplication, and to show their practical bearing. As it is, he leaves the question where Malthus left it, and for that reason his essay may be said to have been born out of due time. Malthus' idea was to persuade the hare, symbolising the increase of population, to go asleep in order that the tortoise, symbolising the increase of subsistence, might gain ground. Professor Huxley's is not quite so hopeful a project. He proposes to spur the tortoise, and to let the hare go on. The method may be a good one; but if the fundamental assumption of the unlimited rate of increase be accepted, it looks at first sight somewhat ineffectual if taken alone. Yet defective as Professor Huxley's argument seems from a rigid point of view, it is sufficiently suggestive, and harmonises sufficiently well with popular currents of thinking, for his advice to attract attention, and probably do much good. But this good will be done in spite of the rather weak reasons by which the advice is supported. It goes without saying that international competition becomes increasingly keener. But there are other elements in the case besides the mere fact of competition. Commerce is exchange of products, and unless one party in an exchange is despoiled by the other, there must be an approximately equal exchange of services. Both domestic and foreign trade, therefore, involves barter, and consequently production on two sides. Our rivals are our customers; and however from the point of view of individual traders we may wish the man in the next street in some distant clime, in order that he may not undersell us at our own door, we do not wish the street deserted, for we know very well that desertion would mean ruin. In precisely the same way we should find ourselves in a serious case if by any means we checked the contemporaneous expansion of foreign nations. Their growth in the main contributes to our own, and their destruction, unless we could immediately re-people their countries, would mean our ruin. Nothing is clearer than that international commerce involves international dependence. So long as we were a self-sufficient community, we might view with equanimity the destruction of a neighbouring nation; but now that the commercial interests of all civilised nations are bound together, whatever affects one affects all. Trade movements in Illinois have prompt reciprocal movements in our own markets. The steamboat and the telegraph have contributed towards making the "perfect market," and towards bringing about the ideal of what has been called cosmopolitan economy—a condition in which trade is carried on by a vast number of individuals competing with each other, national barriers being practically removed. This can hardly be said to be realised; yet so far as the individual trader is concerned, commercially, it makes little difference to him whether his competitor be a fellow townsman, a fellow countryman in the Colonies, or a foreigner. From the national point of view, our plain duty is to see that we effect a fair exchange of our own products against the products of other nations. From the cosmopolitan point of view, one can see that the struggle for existence among the nations is determined largely by conditions other than industrial conditions, for although industry supplies the sinews of war, the most industrious nations have never been the most warlike; and although the most warlike nations have not been the most enduring, military power in the present state of the world is one of the conditions of national existence. That vast military power may exist alongside of indifferent industrial development is evident from the case of Russia.

Although Professor Huxley seems to have treated "the struggle for existence" from the point of view of his own science of biology, in which he is justly acknowledged as a master, with incompleteness as well as discursiveness, his practical suggestions are worthy of careful attention. He suggests two necessary conditions of progress—first, that our produce should be better than that of other nations: second, that society should be stable. In other words, that industry and politics should be as highly organised as possible. There is nothing specially fresh in these suggestions. They have been made before; but Professor Huxley states them with his customary lucidity. The second part of Professor Huxley's paper is indeed a noteworthy contribution to the attempt which has been made during the past few years to establish political economy on a biological basis. There is admirably expressed truth in the propositions, that "a population whose labour is sufficiently remunerated may be physically and morally healthy and socially stable, but may fail in industrial competition by reason of the dearness of its produce. On the other hand, a population whose labour is insufficiently remunerated must become physically and morally unhealthy and socially unstable; and though it may succeed for a while in industrial competition, by reason of the cheapness of its produce, it must in the end fall through hideous misery and degradation to utter ruin." So clear is it that labour like other things cannot be permanently supplied at less than the cost of production. Professor Huxley goes on to discuss educational methods, advocating the adoption of a system of education which should cultivate the powers of observation to a much greater extent than is now done. The branches of special training commonly called technical education, are specified by Professor Huxley as—First, preliminary scientific education, comprising branches of science and art peculiarly applicable to industrial pursuits; second, instruction in special branches of applied science and art, or technical education proper; third, instruction of teachers in these branches; fourth, capacity-catching machinery. As regards the administrative machinery, Professor Huxley holds views similar to those already expressed in these columns when dealing with the Technical Instruction Bills in September last. These are that the School Boards have quite enough to do, and that there are other existing bodies better fitted for the work. On the question of State-provided technical education, Professor Huxley repeats some of the arguments he employed in 1871 in criticising Mr. Spencer's "Social Organism." In quoting from Hobbes, Professor Huxley guards himself against any misconception as to his disagreement with his master upon the sacredness of the sovereign power. Hobbes' views on absolute government he distinctly repudiates; but of the general strain of Hobbes' theory of the State he approves, as against the contention of Mr. Herbert Spencer, that the less we are governed by external agency the better. But here Professor Huxley executes a strategic movement. In 1871 he had argued for the reasonable expansion of the sphere of State action, and had even, by sundry comic analogies, succeeded in throwing some ridicule upon the argument for individual liberty of Mr. Spencer. Then he thought that the State, having accepted the principle of payment by results, could not legitimately stop there; and, having given grants in aid of primary education, could not refuse to give grants in aid of higher education. He had nothing to say then about technical education; but his view as to education generally was that it should be State-aided. Mr. Spencer has to congratulate himself upon a convert. In "repeating and emphasising" his views of 1871, Professor Huxley turns his back upon them. He has become convinced of the fatuity of trusting in State action, so far at any rate as one department of education is concerned, and he has had the courage to say so. "I entertain," he says, "a strong conviction that, in this country at any rate, the State had much better leave purely technical and trade instruction alone." He goes on to say what is very obviously true, that "all methods of technical training are at present tentative, and to be successful, each must be adapted to the special peculiarities of the locality. This is a case in which we want twenty years, not of strong government, but of cheerful and hopeful blundering, and we may be thankful if we get things straight in that time." With these eminently reasonable views, it is surprising to find that Professor Huxley defends the flimsy and unsatisfactory Technical Instruction Bill which was brought in and then abandoned by the Government last session. The Bill did precisely what Professor Huxley has laid down as bad in principle, viz., it handed over to the School Boards, the Education Department, and the Science and Art Department, all of them arms of the State, the control of technical education. This is practice, very different from the principle that the State ought to leave technical instruction alone. It would almost appear as though Professor Huxley's conversion were too recent, and as though he required time to consolidate his views.

PROGRESS IN THE SHIPPING INDUSTRY.

The proceedings of the delegates of British ship owners at the Cannon-street Hotel, London, on the 10th inst., have an interest outside the circle immediately concerned. Our industrial and commercial life is so largely dependent upon the capacity and efficiency of our merchant navy, that whatever affects the latter is more or less felt in every branch of industry, and throughout all grades of society. An occasion like that of the annual meeting of the Chamber of Shipping of the United Kingdom could not, therefore, pass without giving rise to anxious thought and some speculation concerning the future of trade, even if there had been no particular combination of circumstances to render the event specially interesting. But we are just emerging from the gloom of a long period of depression, and our shipbuilding yards are exhibiting evidence by unusual activity of more vigorous life. Moreover, Mr. Scrutton, the newly elected president, had a story to tell of an altered state of affairs, of new conditions to be complied with, and of changing habits and practice. And in all this he was able to discern, and to set forth for the contemplation of his representative audience, steady and constant progress, tending ever, not merely to the well-being of our seamen, a matter in itself of the highest importance, but also to the wider extension of our foreign trade, and the further development of the iron and the engineering industries of this country. It is in this latter relation that the questions raised by Mr. Scrutton will recommend themselves to our readers.

The most striking fact brought forward by the president in his very instructive address was the necessary substitution of steamers for sailing vessels. Of course all are aware that this change is taking place, and has been going on for some years past. But we did not all know, to use Mr. Scrutton's words, which he says express a conclusion drawn from a wide induction of incontrovertible facts, that "sailing vessels, even of the larger type, are found unable to compete with the newest type of steamer." This being so, it follows that the transformation from sailing vessels to steamers will henceforth be made as speedily as possible. Direct evidence was adduced to show that the transformation is, indeed, being rapidly effected. We learn from *Lloyd's Register* that at the end of 1886 the total number of vessels employed in that year was

Digitized by Google

17,917, of which 27·4 per cent. were steamers. Since then further changes have occurred in favour of steam, and judging from the character of the new vessels now on the stocks in exceptionally large numbers, the end of the current year will bring the proportion of steamers up to fully one-third. This is the relative position of steam and sailing ships in point of numbers. But if we estimate their relative importance according to tonnage, we shall find that steam occupies a much more prominent position. Mr. Scrutton justly regards this result as "evidence of the earnestness with which the British ship owner is ever ready to avail himself of the most efficient means and the most approved modes of construction, even though he thereby depreciate his existing property." To the marine engineer the prospect here held out is encouraging. The demand for engines must constantly and rapidly increase, and the need for the utmost attainable degree of economy in these times of keen competition will serve as a powerful stimulant to urge inventors and manufacturers to apply the teachings of modern science, with a view to the production of a more efficient motor. If, when all things are taken into account, triple or even quadruple expansion be found advantageous, that system will establish itself in favour. What the future has in store for us in this direction, it is hard to predict. But the tendency of events seems to be towards a further development of the steam engine; and nothing would so aid the movement as a heavy and growing demand for marine purposes. The evidence presented to the ship owners' delegates on the 10th inst., will, for this reason, be eagerly scrutinised by thousands who have no direct interest in the shipping trade. Of scarcely less importance is another conclusion arrived at by Mr. Scrutton, after a careful investigation of the facts recorded in *Lloyd's Register*, namely, that wood, as a material for shipbuilding, is fast giving place to iron, and that of the latter the form known as steel is most in favour. Here the transformation is being effected more rapidly than in the case of steam against sailing vessels. Mr. Scrutton assures us that composite and wooden sailing ships are no longer being built. An inspection of the building yards at the present time forces home this truth, which our informant deduces from the records of Lloyd's. The origin of this state of things dates back but a few years, and we may see in the rapidity with which the change is being effected a guarantee of its permanence. For this haste in substituting iron or steel for wood, would obviously not be made had the former not proved itself in practice greatly superior to the latter. The demand for iron for shipbuilding must, then, in the future be heavy, and, like that for marine engines, constantly increasing. The prospect before the iron manufacturer is thus a pleasing one, and sufficiently encouraging to invest with interest for him the statements made on this head to the delegates at the meeting of the Chamber of Shipping. The preference shown for steel suggests other questions to which the iron master will not fail to give attention. Following closely upon the re-establishing of basic steel in public favour by the reports of the surveyors of Lloyd's and the Admiralty, the information given on this point is calculated to stimulate into more vigorous life that branch of the iron industry in which we have allowed ourselves to be left behind by our Continental rivals. For the Middlesbrough district the matter is of the highest significance.

THE ELECTRIC LIGHT IN THE CITY OF LONDON.

The decision arrived at by the Commission of Sewers on Tuesday, the 21st inst., with regard to the electric lighting of part of the City, is to be regretted both on account of the electric lighting industry and of the many probable customers in that district, who will thus be deprived of having the electric light in their offices. Some time ago the Brush Company elaborated a scheme for electrically lighting the City between the Exchange and Fleet-street in the north, and Queen Victoria-street and the Embankment in the south. It was proposed to light the streets by means of about 170 arc lamps of 2000 n.c.p., and the houses by incandescent lamps. The annual charge for maintaining an arc lamp was fixed at £26, the company hoping to recoup themselves for possible losses in the arc lighting by the profits made in the private incandescent lighting. It was stipulated that the City should grant the company the exclusive right for laying cables in the streets. The proposal was practically accepted by the committee appointed to inquire into the details of the scheme; but against all expectations the Commission of Sewers did not act upon the advice of the committee, and rejected the proposal. The cost of the public lighting by electricity, if carried out on the principle suggested by the Brush Company, was estimated at £4,400 annually, whereas the gas lighting now in use only costs about half that amount. However, for the extra expenditure of about £3,000 the actual amount of light obtained would have been thirty times that now of gas, and this consideration alone should have secured the adoption of the committee's report. Moreover, business men would have gladly availed themselves of the opportunity thus offered of obtaining electric light from a central station. On their own premises, and where the interests of buyers and sellers of a commodity are virtually identical, there need be no fear of setting up a monopoly. It was, indeed, not on this consideration that the report was referred back to the committee for further investigation, but because a rival offer had been made by the Maxim-Weston Company, who proposed to erect eight hundred arc lamps of 450 n.c.p. at a total cost of £15,000 for the plant, and to work the installation at an additional annual charge of £3,875. Whether this offer be a more advantageous one than that of the Brush Company is a matter of comparatively small importance; but the question before the committee is now, which company can do the work in the most approved manner both as regards public and private lighting. As, however, business men can more easily put up with gas lights in the streets than in their offices, preference ought to be given to the company most successful as regards private lighting. As already remarked, the matter was referred back to the committee, and we trust that the next time their report is presented to the Comission of Sewers they may be able to agree with it, and allow actual work to be started.

Letters to the Editor.

COMPULSORY INSPECTION OF STEAM BOILERS BY BOARD OF TRADE OFFICIALS.

To the Editor of "Industries."

Sir,—The deep feeling of interest I have in the prosperity of the steam using public, and the very serious fear I have of that prosperity being injured and its continued progress hampered by useless, foolish, and uncalled for restrictions, induced me to write you my first letter on this subject, and I do not feel inclined to be led away from the real question at issue by any expressions from Mr. Powis Bale personal to myself. If I am astray in my statements, I will thank him or any other person who will be good enough to set me right; but I expect that the particular statement objected to will be pointed out and proved to be wrong—mere assertions such as contained in Mr. Powis Bale's letter I do not propose to notice. I rely on my facts to speak for themselves without any testimonal from myself as to the length of my experience "amongst boilers" or what schemes I have hitherto advocated, and if they will not do this my advocacy will, I fear, do little to aid their force. I am not the author of a book, but yet all my particulars are taken from the best and most accurate sources bearing upon the subject; such, for example, as the preliminary reports of the Board of Trade officials and the Bill introduced last year. I have quoted verbatim from these in my former letters. But enough by way of explanation, and I am sorry to have been so far diverted from my path, as I want, if it is at all possible, to keep this question entirely free from unnecessary writing.

It is correct that "inspections under the new Act need not be made by the Board of Trade officials themselves," and Clause 8, paragraph 2, is correctly quoted by Mr. Powis Bale, but it is quite misleading to say "that this practically leaves the inspection of steam boilers as it is at present, viz., in the hands of the various boiler inspecting associations," or that it is the intention of the Bill and its promoters that it should be so, as paragraph 3 of the same clause goes on to say: "The Board of Trade, when *satisfied* that in any place in the United Kingdom there is no adequate provision *by any approved boiler inspection society* for the proper survey of boilers under this Act, may from time to time appoint competent surveyors of boilers under this Act, for the purpose of inspecting boilers in that place." It is, therefore, left entirely in the hands of the Board of Trade officials at any time to set down in any part of the kingdom their own inspectors; and what their feeling is in regard to the present boiler inspecting societies, and the probability of their harmoniously working with them, may be gathered by reading those preliminary reports upon explosions of boilers where these societies have been interested. According to Lord Stanley, in his speech made in proposing the second reading of the Boiler Registry and Inspection Bill in the House of Lords, 70,000 of the 150,000 boilers in this kingdom are under the inspection of these societies, and deducting say 5000 as being under the care of the only inspecting association not called an insurance company—which is a greater number than is enrolled in this association—would leave 65,000 boilers coming under the inspection of various boiler insurance companies.

The Assistant Secretary of the Board of Trade, in his report upon the working of the Boiler Explosions Act, 1882, up to 30th June, 1886, states that "inspection by insurance companies does not prevent explosions." If that is a truthful statement, it must follow that it would be requisite "to appoint competent surveyors of boilers" wherever these boiler insurance companies now work, as their inspection could scarcely "be approved" if it fails in the very object for which the proposed Bill is professedly being thrust upon the steam users of this kingdom, viz., "to prevent explosions."

As I have already said, some impression of the feeling of the Board of Trade officials towards the boiler insurance companies may be gathered by a perusal of the preliminary reports written by the Board of Trade inspectors. Of these 243 have been issued to date; and according to the inspectors' statements, 35 relate to the explosion of boilers, kiers, and other vessels and appliances connected therewith, which were under the care of boiler inspecting societies. A thorough analysis of these cases has already been made, and published by the chief engineer of one of the boiler insurance companies, from which it appears that four of these reports (Nos. 68, 89, 145, and 151) refer to the Manchester Steam Users' Association, the one society already referred to which professes that it does not insure boilers, and, consequently, although I must confess I do not at all see why, as four explosions are placed to their credit or discredit, do not come within the Assistant Secretary's unfounded charge. Of the remaining thirty-one cases, it will be found on examination that seven (Nos. 10, 64, 78, 96, 141, and 153) were not boiler explosions at all. Twelve cases reported upon will be found due to causes entirely beyond the control of the boiler insurance companies' inspectors, viz., those given in reports Nos. 29, 39, 41, 56, 60, 79, 93, 104, 105, 134, 159. and 184. Eight other cases—Nos. 25, 35, 90, 94, 116, 118, 140, and 160—could have been avoided if the influence of the boiler insurance company had been sufficient to command attention, and their suggestions had been carried out. No. 83 was reported by the Board of Trade inspector to have been caused by sudden admission of steam into a kier and the corroded state of the bolts of the cover. Of the remaining three cases, Nos. 13 and 23 possibly may, in some degree, have been due to want of sufficient care on the part of the inspector, but it was not proved that such had been the case. Finally, the cases reported under the preliminary reports Nos. 58 and 92 were not under the inspection of any boiler inspecting societies of any kind. In the case of No. 58 the boiler had been proposed to a boiler insurance company, but declined; in that of No. 90, the insurance had lapsed two years previous to the explosion.

If the Board of Trade officials were acting impartially, and were really intending that the boiler inspection of this kingdom should remain in the hands of all the boiler inspecting societies, would the Assistant Secretary to the Board of Trade go out of his way in his report to make this most injurious attack upon boiler insurance companies? This attack appears to be entirely inexcusable, as the Board of Trade inspectors had all the particulars before them, and were well aware that the boilers were not under the care of the insurance companies. Still the Assistant Secretary repeats the charge in his report which is written long after the explosions, and with the real facts before him.

Although the attention of the Board of Trade officials has been drawn to the fact that Nos. 58 and 92 were not under the inspection of any boiler insurance company, and the facts of both cases brought within their knowledge, no admission of error, or apology for the wrong done, has, so far as I can gather, yet been made.

It will no doubt be admitted by thinking men that the facts of the case, as here described, are ample to show the disposition of the Board of Trade, and the extreme improbability of the long continued existence of boiler insurance companies should the Boiler Registry and Inspection Bill unfortunately become law. "Inspection by insurance companies does not prevent explosions," says the Assistant Secretary to the Board of Trade, after five years' experience. Could the Board of Trade stultify itself by appointing boiler insurance companies to survey boilers after such a conclusion? Again, it must not be overlooked that, even were it possible that the Board of Trade lion and the boiler insurance companies' lamb would lie down together peacefully (or, say, with the lamb inside the lion), the position of the steam using public would not be one whit the better—the same rules, regulations, and restrictions would be enforced, otherwise the boiler insurance companies would not be "approved." The boiler insurance companies or inspecting societies would merely become tools in the hands of the Board of Trade officials, and mere mechanical executors of their will. It is further assumed by Mr. Powis Bale that I should "probably not deny that *thousands of boilers are in use that ought to have been on the scrap heap years ago.*" If that is intended to mean that thousands of boilers are in use that are not safe to work, or in any way dangerous either to limb or life, I do most emphatically deny it; but if it is merely intended to convey a fact which has no relation or interest to us with regard to the question before us—that there are thousands of boilers which for motives of economy or superiority in working might be replaced with advantage, I should admit it cheerfully.

The question of certificating attendants is not before us, and can be dealt with at the proper time.

Compulsory inspection of steam boilers is at present in force in America, France, Germany, and Switzerland; but the returns of boiler explosions show that the number of explosions exceed those in this kingdom both in number and fatality. I need not at this juncture enter into this part of the question, but will merely remark that the old fable of the fox that had lost his tail does not appear to be fully appreciated by some persons even yet; those who are acquainted with the working of boiler legislation in America will appreciate my allusion. My contention is that no case has been made out for compulsory inspection by the Board of Trade officials; that no further legislative interference is necessary; that the present Boiler Explosions Act of 1882 is ample for the work required, and the result of the last four years' experience has shown most conclusively that all that is needed is to put its provisions in force, and that explosions (except those due to inevitable accident) will cease to occur.

Yours, &c.,

Manchester, 18th February, 1888. Economiser.

PROPOSED LEGISLATION FOR STEAM BOILERS.

To the Editor of "Industries."

Sir,—I have read with much pleasure your able article on this subject in your last week's issue, also the very able letter of your correspondent "Economiser," and with your kind permission I would like to say a few words on the same subject. The first question to be considered is, do we, or do we not, stand in need of further legislation? Up to the present there would seem to be a feeling that we do, while the members of a very representative association, viz., the Oldham Chamber of Commerce, have voted almost unanimously that we do not. On the other hand, another equally representative body, the Blackburn Chamber of Commerce, can see no objection to the proposed Bill, beyond that the cost of working is not very clearly stated. No doubt the Blackburn Chamber can see no objection to a Bill to enforce that which they have voluntarily adopted with great advantage to themselves, viz., independent inspection by those who have made boiler keeping a specialty; consequently boilers in their district are well kept, economically

Digitized by Google

worked, and practically free from explosion. The Oldham Chamber, however, observe everything that is bad in the proposed Bill; but why the members view it in such an evil spirit I fail to understand, as my experience of the Oldham district is that, with the exception of perhaps one large firm and a few very small ones, the shoe is not at all likely to pinch steam users, because the Oldham boiler owners generally have voluntarily adopted the course the Bill seeks to enforce, and had any other gentleman occupied the chair the result might have been different. The chairman seems to have had a dread—quite unfounded, in my opinion—of the Bill creating a vast trades union of certified boiler attendants, which would of course be a tender string to play upon in the presence of a body of employers. The Bill, however, proposes nothing of the kind. It is time, I think, that something was done for the public safety, either by more effectually applying the present law, or amending the same. The unscrupulous cannot be allowed to go on for ever holding the lives of the public in their hands, and by simply pleading ignorance escape justice, as has been done in scores of cases since the passing of the Act of 1882.

In your article you mention the fact that in Section VII. of the Act, "the court may order the cost of preliminary inquiry or formal investigation," &c., &c. This is correct according to the Act, a copy of which I have now before me, but nevertheless it is a most misleading clause. In fact it appears to be impossible to carry it out, for Mr. Gray, in his fifth report on the working of the Act, says: "By the terms of the Act a court of formal investigation has power to order costs and expenses of inquiries or investigations;" and further on he says, "but no provision of this kind is made in cases in which only a preliminary inquiry is held." This fully explains what has often been asked, "Who pays the cost?" Mr. Gray tells us that "these have to be borne by the Government, while the person really to blame finds himself exempt from all liability as regards cost." I think there are few of your readers but will admit that some alteration is required here. Your correspondent "Economiser" appears to be one of the very few who peruses the various reports. I hope he may not be as unfortunate as myself, as I have to *buy* mine; and it is buying them, too, for I have them all, and with the exception of the first few reports, I do not hesitate to say that they are the most expensive and most uninstructive literature in my house. Still I get them—partly for amusement, and partly to see how inconsistent a public body can be. "Economiser" refers to the explosion dealt with in report No. 145. I would, however, draw your readers' attention to report No. 79, in which it is stated that a Cornish boiler had a weak flue, and was fed with water of a corrosive nature. The inspector for the insurance company under whose care it then was, advised in December, 1882, "that a ring should be fitted round the centre of the flue to strengthen it." The flue collapsed in March, 1884, at which time we are told in the report that "the boiler was not insured." Mr. Loxdale, of the Board of Trade, who reported that the above advice had been given, remarks: "From the evidence, I find that everything was considered to be in satisfactory condition." And in a few lines further on he states: "I am of opinion that if the boiler had been inspected by some one competent to do so, the defects would easily have been seen, and the explosion prevented." But how does he reconcile this with the fact that the firm had been actually advised to strengthen the very part that had failed? Even Mr. Traill himself says: "The recommendation of the insurance company was not attended to with reference to strengthening the flues." I might here ask, how would the inspector have fared had he neglected to advise the strengthening of the flue?

If anyone would like to investigate a mass of probable perjury and intimidation before an official tribunal, let him take a glance at report No. 129. Here he may see how easy it is for skilled malice to plead ignorance and escape justice.

Up to the present the Act has been carried out by special men rather than by men of special experience, and in many of the cases inquired into, the condition of, or omission of, a fitting that might have caused or prevented the explosion, has not been so much as mentioned. For instance, by referring to report No. 89, we see that the furnace collapsed through shortness of water and consequent overheating, the boiler was fitted with fusible plugs and low water valve, but we are not told that any inquiry was made into their condition. Report No. 184 refers to a similar case, still the low water valve was not mentioned except to show that it was there. In the recent explosion at Tinwell, in Rutlandshire, it was clearly shown that it was a case of shortness of water, still Mr. Woodthorpe does not suggest a fusible plug or low water valve as a preventive in such cases against overheating and collapse.

The latest feature of inconsistency is to be found in report No. 244, just issued. A boiler 31½in. diam. by 7ft. long, with flat ends, had one of them blown out. Mr. Watson, in searching for information, or a parallel case, refers to an experiment carried out by Mr. R. Wilson on a similar boiler, and states: "With the exception of the shell being 1½in. less in diameter, the end was practically identical with that of the exploded boiler when new." . . . . "The end plate gave way at a pressure of 371lb. per square inch." Although the exploded boiler only worked at 30lb. Mr. Traill remarks: "This is a case where the grooving of the end plate was due to working the boiler at a greater pressure than the end was fit for."

These are only a few cases out of many which are given simply to show that whatever is done by way of legislation, the Board of Trade authorities have not as yet shown that knowledge of land boilers and their working, to lay claim to the confidence of the public in the framing of a Bill. What is somewhat singular in this connection is, that to become a Board of Trade surveyor, one must apply young, and have what is thought the very necessary qualification of having been "five years at sea in charge of engines." How this will help the surveyor at a cotton mill or other land boiler explosion, I fail to see; still such is the constitution of the body who would now take over under their control *nearly all* our land boilers. One of your correspondents, who claims an experience of twenty-three years, gives me much surprise when referring to the length of time a boiler can be considered safe. I have nearly lived in boilers and flues for the last twenty years, and have seen some of their worst cases, and studied their worst diseases; still, under ordinary conditions, I should have no hesitation in stating whether or not a boiler was safe for twelve months, or whether it was not safe at all. Unfortunately, whenever the grinding stone is being turned by an unsuspecting philanthropist, there is sure to be some one ready with an axe to grind. The Board of Trade reports show most conclusively that if there is to be legislation at all, it must be for the boiler and not for the man, as we now have far more *skilled malice* than *ignorance*. Taking ignorance and negligence together, they only affect nineteen cases out of 223 explosions, and, strictly, seven of these were outside the control of the attendant, thus reducing the actual number to 5 per cent. But the first question, "Do we need further legislation?" should be settled before criticising too much the present Bill, or deciding who shall frame the next.

Apologising for troubling you with a letter of this length,

Yours, &c.,

Manchester, 18th February, 1888. CHALK LINE.

To the Editor of "Industries."

SIR,—Another attempt to extend the objectionable system of State intervention in the commercial and industrial organisation of the country is likely to be made this year. On the 15th August, last year, on the motion of the President of the Board of Trade, the Boiler Registry and Inspection Bill was read a second time in the House of Lords, and thus in principle at least adopted. It was then withdrawn, but will probably be introduced again this session, after having been considered by a Select Committee of the Upper House.

The Bill is promoted by the permanent officials of the Board of Trade, and, if allowed to become law in its present shape, will place both boiler makers and boiler owners utterly and absolutely at the mercy of the Board by inaugurating a system of inspection and control, the severity and comprehensiveness of which will probably astonish those who have formed their opinions from the Parliamentary intelligence in the daily papers, without a knowledge of the text of the Bill itself. It is to this ignorance of the true character of the Board of Trade's proposals that the absence of any combined and public opposition to the Bill must be attributed. Indeed, the occurrence of such expressions as "The Board of Trade should be assisted by a committee of experts from all the different interests," "Government inspection was not proposed," "It was desired to extend the benefits of the existing inspecting associations," in the reports of Lord Stanley's speech of the 15th August, were so likely to mislead, and convey so entirely false an impression of the real objects of the measure, that some further explanation is required to rouse manufacturers and tradesmen to a true sense of the danger that awaits them. What, then, do these expressions really mean? Take that relating to the appointment of the committee. A manufacturer reading only the newspaper report of Lord Stanley's speech might reasonably conclude that, although the President of the Board of Trade would be the official head of the new system, a really representative committee would be appointed to do the work in framing rules, supervising inspections, and safeguarding the interests of boiler owners; but if he turned to the Bill itself he would soon become aware that the promoters intended themselves to be the sole authority, and had accordingly taken all requisite precautions against being foiled by a committee, or coerced by outside influence. The Bill, in fact, provides (Clause 15 [1]) that the Board of Trade may make, rescind, and vary rules with respect to the mode of survey of boilers, the conditions under which certificates may be issued, the forms to be used, the fees, allowances, and expenses to be paid, and any other matters authorised or directed by the Act to be prescribed. Also (Clause 7 [1]) that, for the purpose of "*advising*" only on any rules for the survey of boilers, the President of the Board of Trade (in reality the permanent officials) *may* (not shall) appoint a committee, each member of which shall be nominated by him for a period of two years (Clause 7 [3]). If the members so nominated are sufficiently subservient they may be re-appointed, but (Clause 7 [3]) if the committee prove recalcitrant it may be packed by the addition of such persons having special knowledge of the construction and use of boilers as the President may select; and finally, to make assurance doubly sure (Clause 7 [5]), the constitution of the committee may be altered indefinitely by an order of the Queen in Council.

Is it uncharitable to conclude that the committee is a solemn sham? got up to hoodwink the public and disarm opponents in the first place, and afterwards to be a scapegoat to bear the odium which the enforcement of the Board's rules, regulations, and changes will inevitably excite. Nor are the statements that "Government inspection was not proposed," and that it was "desired to extend the benefits of the existing inspecting associations," less delusive. The naked truth is told in Clauses 4, 6, and 8, which state that every "boiler," *i.e.*, "every closed vessel which is used for generating steam, or for heating water, or for heating other liquids, or into which steam is admitted for heating, steaming, boiling, or other similar purposes, with all the setting equipment and fittings," used within the United Kingdom, whether on land or afloat; and every boiler used within the territorial waters of the United Kingdom on board of any British ship (with some exceptions to be noticed further on) shall be *registered by an officer of the Board of Trade*, and shall be surveyed once at least in twelve months by a surveyor appointed by any society, company, or body of persons, *whose rules for the time being are approved by the Board of Trade*, or *by a surveyor directly appointed by and removable at the pleasure of the Board of Trade*, and shall not be used without the certificate of such surveyor. Having regard to the provisions of Clause 15, referred to above, it is difficult to see how inspection under these conditions differs from the "Government inspection," which is "not proposed," or how the present employment of societies, companies, and bodies of persons to carry out the rules which the Board may formulate, can be considered as a guarantee that the *status quo* of the existing inspecting associations shall be maintained. On the contrary, the demand for powers to make all rules and regulations, to appoint and dismiss surveyors, to appoint inspectors (a sort of superior surveyor), to fix payments and allowances, to constitute itself sole arbitrator in disputes between owners and surveyors, together with the assumption of the right to forbid the prosecution of anyone for offences against the Act, would seem to show that the Board is aiming at monopoly of inspection, and that as soon as it has appointed and organised the necessary staff, it will make short work of the societies and let loose on boiler owners a swarm of officials, who, whether competent or incompetent, honest or dishonest, courteous or overbearing, will be completely masters of the situation.

The reason of the desire expressed to extend the operations of the existing inspecting associations now becomes apparent. In the extended sense adopted by the Board, there are probably about 500,000 "boilers" to be inspected in twelve months; therefore, even if boilers are laid off with strict impartiality, regardless of the convenience of the owners, at least 1370 must be inspected daily. Well may the Board of Trade propose to delegate the business of inspecting to existing bodies, at least until the latter have evolved a system capable of grappling with the work, and have borne the odium of licking the astonished boiler owners into shape. And what are the reasons alleged for all this fuss? Simply the statements of the Assistant Secretary of the Marine Department of the Board of Trade, that he has discovered that the "term 'accident,' as applied to boiler explosions, is a misnomer," and that he has found that during the last five years the numbers of lives lost from explosions of such "boilers" as would come within the scope of the new Act has averaged thirty per annum. These at least are the reasons put forth by Lord Stanley in his speech. The loss of thirty lives a year is doubtless a serious calamity; but does the Assistant Secretary wish it to be inferred that he has discovered means by which, if he gets the powers he demands, boiler explosions will be entirely prevented, and thirty lives a year now sacrificed will be preserved? If this be true he is to be congratulated, for hitherto it has always been believed that no system of inspection, least of all Government inspection, would entirely prevent explosions. Otherwise his statements cease to have a logical connection with each other, and forfeit the claim to originality, which they possess when taken conjointly. They degenerate, in fact, into the tiresome repetition of a well worn commonplace, followed by an abortive effort to make a mountain from a mole hill, in order to extenuate the unwarrantable plot to foist upon the nation a new department, with additional berths for place seeking officials, in direct opposition to the deliberate opinion of the Select Committee of 1871, and in the absence of any public agitation or demand for such a step.

But even if further legislation were a recognised necessity, the present measure would stand condemned, not only by the objectionable character of its clauses, but by the palpable inconsistency of its promoters. If the principle affirmed by the House of Lords were carried into practice, all boilers should be subject to the Board of Trade; but in Clause 24 of the Bill, we read that this Act shall not apply to the boiler of any ship for the time being classed in Lloyd's registry of shipping, to any boiler belonging to or used exclusively in the service of Her Majesty, to the boilers, stationary as well as locomotive, belonging to any of the railway companies, or to any boiler used exclusively for domestic purposes.

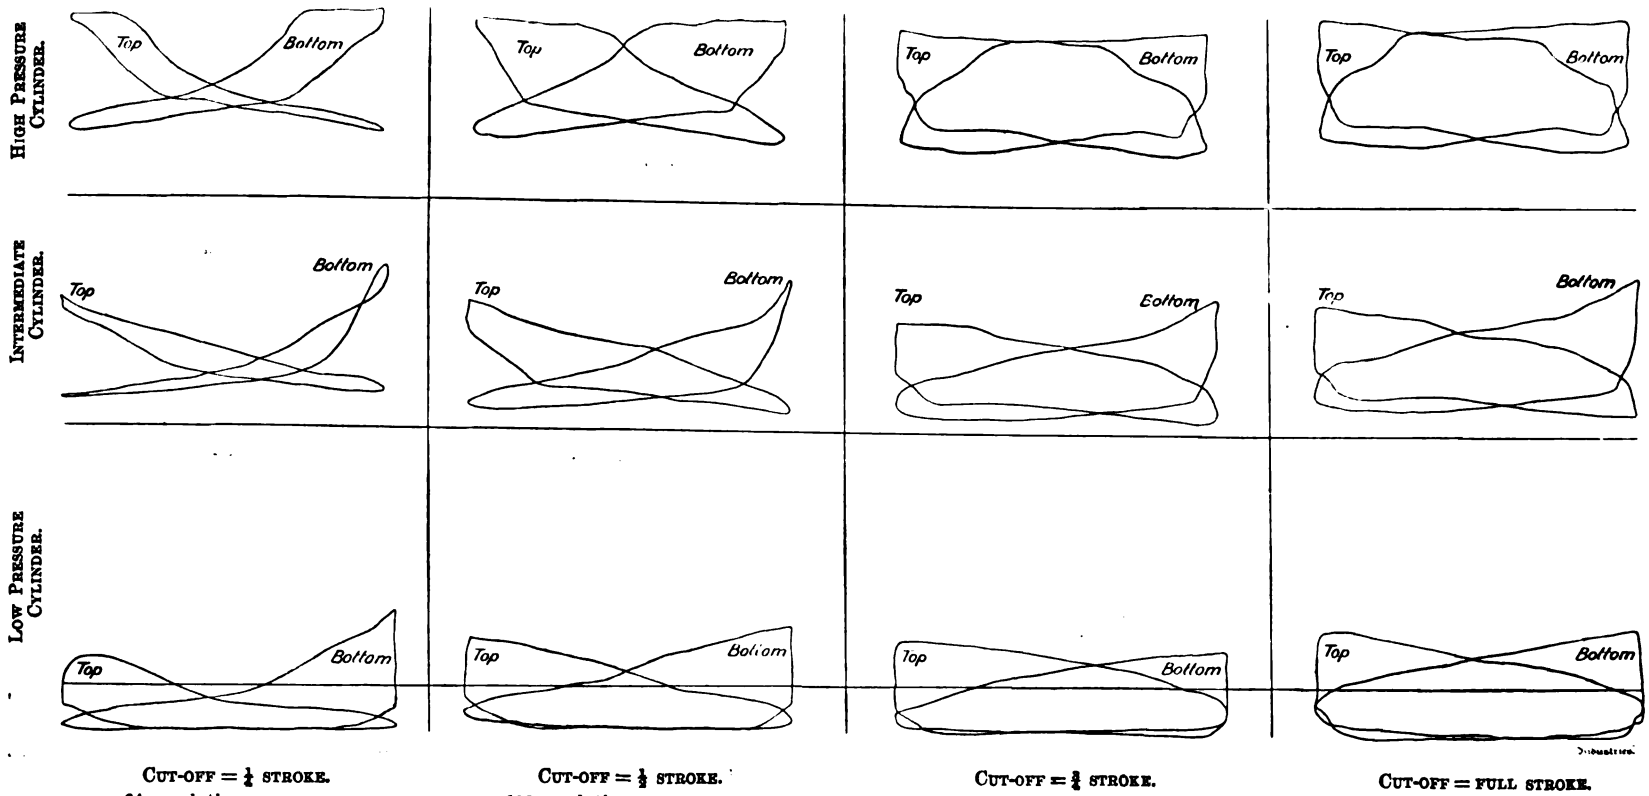
Why should these boilers be excepted? Simply because the promotors knew that to include these would insure the shipwreck of their Bill. Lloyd's Committee had declined their interference, Her Majesty's Navy would not sail under the Assistant Secretary's flag, the railway companies would not be engineered by the Board of Trade surveyors, the public generally would not admit the paternal government official within its doors. The Board's defeat by Lloyd's Committee is instructive. These boilers were originally included in the Bill; but the committee got wind of this, held a meeting, and plainly declared that Board of Trade inspection should not be for them.

Lord Stanley covers the Board's defeat by justifying the exemption on the ground that these boilers are already subject to inspection. If this be a sufficient reason, why were they ever included in the Bill? And why has the Board included the 70,000 boilers which Lord Stanley says are inspected by the various boiler inspection companies, whose inspections the Assistant Secretary himself admits "have in the main been conducted on a satisfactory system?" Why? Because the owners of the latter are private firms or individuals, incapable in their isolation of dangerous resistance. Let, then, isolation and indifference cease; unite in opposition to the Bill before it is too late; declare, with no uncertain voice, that you will not submit to an official despotism, seeking to magnify its own importance and extend its influence at your expense; let the chambers of commerce, your trade associations, and your Parliamentary representatives be your spokesmen. The Select Committee and the House of Commons will listen to them.

Yours, &c.,

20th February, 1888. PRO BONO PUBLICO.

P.S.—Since the above was written I have read the letter from the author of a "Hand Book for Steam Users" in your last issue, in which the opinion is expressed that the Bill practically leaves the inspection of steam boilers as it is at present. It certainly would seem as if he, rather than "Economiser," had misunderstood the import of the Bill.



To the Editor of "Industries."

SIR,—I have read with much interest your able leader on the above subject, and your correspondents' letters. It always appears to me that a vast amount of unnecessary labour and, in some cases, failure and annoyance might be avoided if our legislators, and those whom in any particular instance their measures more immediately concern, would condescend to carefully study what has been done in other countries in the same direction, instead of trying to work out *de novo* problems which have been already wholly or partially solved by others. I am well aware that the legislation suited for one nation cannot be advantageously adopted wholesale by another, but must be altered to suit varying conditions. Still this is no excuse for ignoring foreign experience and blundering along blindly in insular self-sufficiency, a course which, it seems to me, we are as a nation too prone to follow. While believing that your correspondent "Economiser" is too sweeping in his condemnation of the proposed legislation, I quite agree with him that to impose any hard and fast rule as regards the factor of safety for boilers would be an irrational and uncalled for proceeding, and would afford no satisfactory guarantee against risk of explosion. While one boiler may be perfectly safe with a factor

of 4, another with one of 6 may be a menace to life and property. This depends on the nature and condition of the material of which the boiler is made, as well as on the method of construction and the setting; both the latter are very important items determining the life of a boiler. No factor of safety, however high, and no material, however excellent, will entirely compensate for bad design.

According to the German official regulations, all boilers intended to work with a pressure not exceeding 74lb. per square inch are tested by water to twice this amount, and in all other cases to a pressure exceeding that at which they are to be used by five atmospheres. When thus tested there must be no permanent alteration of form—no set, in fact. For the purpose of measuring the extension, and ascertaining whether any set takes place, an ingenious and simple instrument has been devised by one of the official inspecting engineers. This method, if thoroughly carried out, is, as far as it goes, far preferable and more rational than any arbitrary regulation as regards the factor of safety; it really insures the working stress remaining well within the limit of elasticity, and if the test be repeated at sufficiently short intervals, it undoubtedly gives a very reliable indication of the condition of the boiler. By its use, deterioration of the material, damage to the plates by corrosion, cracking at the rivet holes, grooving and bulging, could all be discovered by the increased or unequal extension and deformation of the boiler, if the investigation were carried out with sufficient thoroughness, in conjunction with a careful inspection. The good or evil results of legislation of the kind in question depend to such a large extent—it would scarcely be an exaggeration to say *entirely*—on the competency of the inspectors. The latter must be men of knowledge, experience, and judgment, which they should be at liberty to use, unimpeded by red tape, to the best of their ability. On the one hand there must be no wooden uniformity of rule applied without regard to circumstances to all boilers alike, on the other no mere perfunctory officialism. I would venture to suggest that instead of the appointment of Government inspectors, inspection by authorised private associations should be made obligatory, and the responsibility for explosions brought home to the latter by heavy fines; the maximum fees to be charged must, of course, be settled officially with regard to the statistics of boiler explosions, so that the occurrence of an accident to a boiler under the care of any inspecting company would very sensibly reduce the profits of the latter. Before, however, any fresh departure in boiler legislation is taken, it certainly seems only reasonable—as you suggest—that the Board of Trade officials should be called upon to make a fuller use of the powers they already possess.

Yours, &c.,
G. R. BODMER.

THE VALVE GEAR ON THE GUNBOAT "CERAM."

TO THE EDITOR OF "INDUSTRIES."

SIR,—I have noticed in your issue of the 20th ult., an illustration of a set of triple expansion engines built for the Dutch Colonial Navy by the Shipbuilding and Engineering Company of Flushing, in which one of the special features was that the three valves were worked by only two sets of valve gear. Will you allow me to draw the attention of your readers to the illustrations and description of a set of triple engines having the same peculiarity, and which appeared in the issue of *Engineering* for 18th February, 1887? For this system of working the three valves of a triple engine by only two sets of valve gear (employing "link" or any other gear), I have patents in England, and such other of the continental countries as I thought would pay for the expense of patenting; and I have already had several sets built on this plan, which have given entire satisfaction. One set now under construction will indicate about 3500 h.p. For Holland I did not take out a patent, so the engines you illustrate do not concern me commercially. Technically they do, however, interest me, as I have found that this system, which I have worked in connection with my ordinary valve gear, gives most satisfactory results. The distribution of steam is exceedingly good, as your readers can see for themselves by the annexed series of diagrams of the engines of the steam yacht "Cassandra," taken at various points of cut-off. It will be seen that throughout the series the middle valve, which depends for its motion on the combined motions of the other two, produces as correct and efficient a distribution of steam as either of them. So far therefore as the action of the gear is concerned, it is quite satisfactory. It also saves a number of parts, and is very simple; but it has the drawback, which no doubt limits its wider adoption, that all three of the engines are not complete and independent in themselves. Though in my arrangement I make each of the outer engines complete by employing my ordinary valve gear, which is naturally in the plane of the valve spindle, the middle one is yet dependent on the other two. In the Dutch engines the whole three mutually depend on their connection through the floating lever, and a failure of any part of this combination would be fatal to the whole, while a similar failure in mine would affect one or at most two only of the cylinders, leaving one to struggle on, but that one perfect.

Yours, &c.,
DAVID JOY.

London, 11th February, 1888.

THE GROWTH OF ELECTRIC LIGHTING IN THE UNITED STATES.

STATISTICS recently published by the New York *Electrical World*, afford a striking example of the rapidity with which new industries are taken up and developed in the United States. We learn from the above source that at the beginning of 1886 there had been established 450 local electric lighting companies, whilst at the present time the number has increased to one thousand. These are companies running central stations for the supply of arc and incandescent lighting to subscribers. The total number of such stations now running in England is probably below twenty. In addition to these stations, there are said to be three thousand isolated plants at work. The total number of arc lamps in use throughout the United States is roughly estimated at 200,000, whilst about 1,250,000 incandescent lamps are nightly in use. The greater part of the arc lighting is done from central stations, whilst the larger share of the incandescent lighting falls to isolated plants. It is estimated that 150,000 arc lamps are supplied from the thousand central stations, whilst only 500,000 incandescent lamps are supplied by them. If we estimate the life of incandescent lamps at one year, the lamp renewals alone would amount to 1,250,000 lamps, representing an annual expenditure of £250,000, in addition to the cost of the current. The charge for an arc lamp varies between £15 and £30 annually, and, taking £20 as a low average, this would represent a gross income to the central stations of £3,000,000.

THE PHOTOGRAPHIC EXHIBITION AT THE CRYSTAL PALACE.

ON Monday, the 20th inst., an Exhibition of Photographs, and of apparatus connected therewith, was opened at the Crystal Palace. The artistic aspects of the Exhibition are not within our province; but in their scientific aspects the pictures may be divided into four great classes, viz.: (1) Silver prints upon albumenised paper, which, although very beautiful, are likely to fade in more or less time; (2) developed silver prints, which are more permanent; (3) carbon prints, in which the colouring matters are in ordinary pigments, so that the pictures are relatively permanent; (4) platinum prints, in which the pigment is platinum black, a substance more durable than the paper on which it is supported, so that such pictures may be taken and preserved for historical purposes; and they have an engraving-like beauty.

As regards apparatus, Messrs. Marion & Co., of Soho Square, London, have amongst their exhibits a new lamp for the production of the magnesium flashing light, for photographic purposes; it consists of two Argand oil burners, through the centre of which a weighed charge of magnesium powder may be blown by means of a pneumatic ball and flexible tube. Another feature at their stall is a kind of cabinet designed by Mr. A. Cowan, which when opened displays a porcelain sink with taps for water supply, shelves with bottles of chemicals, non-actinic lantern, drawers, and all kinds of useful accessories for developing negatives.

Mr. W. W. Rouch, of the Strand, London, has among his exhibits a "detective" camera, simple in its details, and free from the weight of a number of dark slides to hold the plates, which latter are stored close together, and brought successively into position, partly by what is known as Mr. Samuels' plan, and partly by an addition thereto by Mr. Rouch. These cameras are carried under the arm of the operator, who by touching a spring takes pictures instantaneously. In a large tourist's camera, exhibited by Mr. Rouch, the front consists of a wooden cross panel carrying the lens, and of leather, which can be folded, whereby the weight is reduced.

Digitized by Google

Messrs. Mawson & Swan, of Newcastle-upon-Tyne, exhibit among other things, a simplified photomicrographic camera, which is a common camera of long range, with a flange adapted to the standard objective screw of the Royal Microscopical Society; two little rods project from the lower part of the flange, and carry a sliding stage, upon which the object to be photographed is placed. The object is then lighted with the usual lamp and condenser.

Messrs. R. & J. Beck, opticians, London, exhibit a detective camera, fitted with a Newman's shutter and an iris diaphragm, which are two useful contrivances in practical work. Among their exhibits is a nickel pocket case, measuring 4in. by 3in. by ¾in., containing three bottles and a measuring glass. The bottles contain solutions concentrated enough to develop sixty quarter-plates; this is designed for the use of tourist photographers, with whom saving of weight is usually a great object

The Paget Dry Plate Company, of London, have a large store of their plates. Mr. B. J. Edwards, of Hackney, London, shows orthochromatic plates, which give colours more in their true monochromatic relation than do other plates. With the latter, yellow may come out black in the positive, and dark blue nearly white; in orthochromatic plates this photographic defect is largely remedied. Two or three years ago Messrs. Braun, of Dornach, were selected to photograph the pictures in the National Gallery, because at that time no English photographer could do the same quality of work; this arose from their not having then fully recognised and studied the various discoveries made on the Continent in orthochromatic photography.

The Dresden Albumenising Company, of Dresden, exhibit samples of their albumenised paper, and of good photographs produced thereupon. Messrs. G. Haughton and Son, of High Holborn, London, exhibit a cabinet washing sink, and a portmanteau, tin lined, in which the camera, accessories, and chemicals can be packed. When empty, it may be used as a developing box, and one half of the tinned interior serves to catch the washing waters and drippings incidental to developing operations.

Mr. J. H. Steward, of the Strand, London, exhibits a new gas regulator for use with the bottles of condensed gases employed for the oxyhydrogen light. It consists of a bellows working against a spring, the tension of which regulates the position of the needle which controls the flow of gas. At our visit, the gas pressure in the bottles was stated to be 120 atmospheres, and the regulator was adjusted to work at the pressure of 12in. of water. Among Mr. Steward's exhibits were two flat rods, or "platforms," with adjusting screws, to be placed in the optical lantern, and to carry two slides of plain glass, with opaque cross lines ruled on each. The object of this arrangement is, that when dissolving views are to be exhibited, the views from the two lanterns shall be accurately placed in relation to each other on the screen, and without some such device the making of the adjustments is a matter of time and difficulty.

Messrs. J. Swift & Son, of Tottenham Court Road, London, exhibit a photomicrographic camera for the difficult work of photographing bacteria and other objects requiring extremely high powers.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

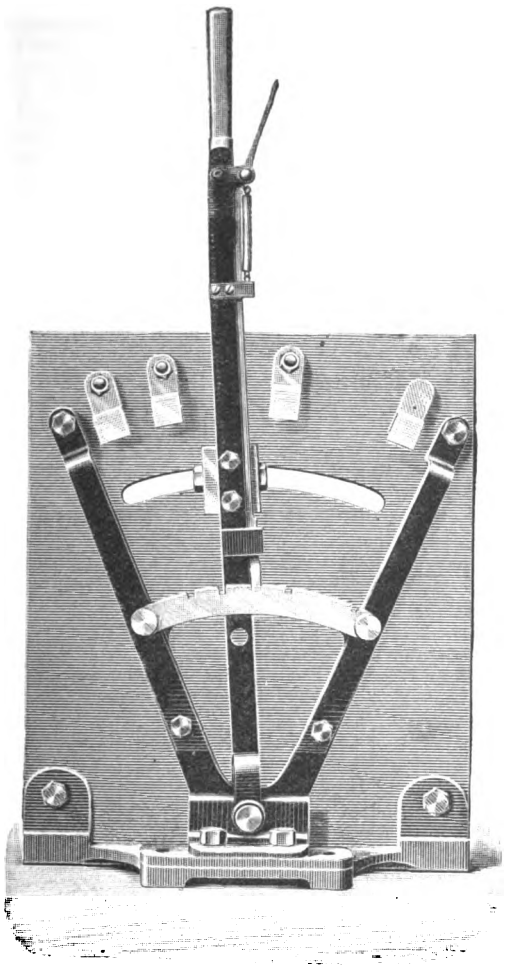
The discussion on the two papers dealing with transformers, which were read before this Society on the 9th inst., was opened at a special meeting on the 16th inst., by Professor Ayrton, who referred to the difficulty of accurately determining the energy developed in a circuit by an alternating current when that circuit contains self induction. In the early days of transformers it was customary to measure the potential difference between the terminals of each coil by a high resistance dynamometer, and the current by a low resistance dynamometer; but this introduced errors from two causes. In the first place, the high resistance dynamometer had itself a considerable self induction, and the current passing was not a true measure of the potential difference which it was intended to measure, and, in the second place, even had this cause of error not existed, the product of potential difference and current so measured would not represent the true work. Other methods must, therefore, be employed, which the speaker subsequently described. He was of opinion that, apart from the lag in the electric circuit, there is a distinct lag in the magnetic circuit, owing to which the magnetisation takes place later than the current which produces it. Having referred to the employment of the electrometer for measurements of alternating potential differences, which was first employed by M. Joubert, and to the improvement upon this method, due to the speaker and Professor Perry, by which the true work in a circuit containing self induction could be found, he stated that this method, although perfect in theory, is only applicable if the law as generally assumed for the electrometer is correct; but, inasmuch as most electrometers do not follow this law, the method is of little practical use, and he preferred to measure the work of an alternating current, not electrically, but by use of a calorimeter. Such measurements were recently carried out by the third-year students at the Central Institute on a transformer which was lent him by the author of the paper. The arrangement was as follows: The transformer was soldered up in a closed metal box, the top of which was provided with a tube, through which projected the four leads for connection respectively to the dynamo circuit and to the lamp circuit, having no self induction. In the tube there was also room for the insertion of a thermometer, by which the interior temperature of the calorimeter could be ascertained. The inner box was placed within another box, and the intervening space was filled with water, a continuous stream being maintained which entered at the bottom and issued at the top. The work done in the secondary circuit could be ascertained by the usual electrical measurements, and that converted into heat in the calorimeter was ascertained by taking the difference of temperature between the inlet and overflow water, and the quantity of water flowing per second after the conditions had become constant. To show how far the old methods of measuring were erroneous, the speaker also inserted in the primary circuit an ordinary wattmeter, a Siemens dynamometer, and a Cardew voltmeter. The wattmeter would of course indicate at a glance the apparent watts, the readings of the Siemens dynamometer and the Cardew voltmeter would, if multiplied, also be an indication of the apparent work, but both these measurements are necessarily too high. The calorimeter gave exactly the energy lost in transformation and converted into heat, and the electrical measuring instruments in the secondary circuit gave exactly the energy flowing through that circuit. By adding the indication of the calorimeter to the energy in the secondary circuit he obtained, therefore, with great accuracy the work supplied to the transformer from the machine. The following table gives some of the figures obtained:—

Measured by wattmeter.	Measured by dynamometer and voltmeter.	Measured by calorimeter.	Energy in secondary circuit.	True energy supplied to primary circuit.
136·9	182·2	53·2	—	53·2
1764·0	1559·0	55·6	1484·0	1539·6
3305·0	3035·0	118·8	2773·0	2921·8

The transformer was nominally of 2 h.p., but the speaker found it quite feasible to work it up to 3 and nearly 4 h.p. without any difficulty, and he thought that the author of the paper in making transformers seems to have followed the custom of agricultural engine makers, who classify their engines by a nominal horse power, which is much below the actual.

The next speaker was Captain Cardew, who explained his safety apparatus by comparing the iron box to a trap for any stray volts leaking out of the primary circuit, and the aluminium foil to the bait. It is important that these foils should be perfectly flat, and for this purpose a supply of spare foils is carried in a gun metal case. When taking one out it must be handled at the end which is to remain in contact with the bottom of the box, so that the other end which lies below the disc and is attracted by it may not be in any way deformed. The speaker showed one foil which had been used several times over, and the only damage it had sustained was the burning out of two small pieces, one at the circumference of the disc, and the other a little way down on the shank. Referring to the question of hysteresis treated by the author, he compared this phenomenon to the molecular friction which takes place in a spring when deflected, and which is quite distinct from the energy stored in the spring. If the spring is alternately deflected to opposite sides the energy required in one movement is given back in the next, but that absorbed by molecular friction which heats the metal is lost. The same distinction must be made in magnetising the core of a transformer. The energy of the magnetic field is given back at each reversal, but that required to overcome hysteresis is lost. He did not approve of the Kent dividing sheet, because of setting up an unnecessary strain in the insulation of the primary circuit. The same objection might be urged against the device of grounding one terminal of the secondary circuit, which was mentioned by Professor Ayrton as a better safety device than either Mr. Kent's or Captain Cardew's appliances. The reason of his objecting to the grounding of one point on the secondary circuit is that the insulation of this circuit is at once lowered, and a strain is set up in the insulation between the primary and secondary circuits.

Mr. Bernstein was of opinion that the series system had many practical advantages over the parallel system of working transformers, not the least of which was that the potential difference between the terminals of the primary coil of each transformer could be kept within fairly low limits, say from 50 to 100 volts. In the parallel system this potential difference is necessarily high, 2000 volts or more, and the difficulties of insulation are correspondingly increased. He objected to the Kent dividing sheet as a safety appliance on account of its leading, so to speak, the primary current into temptation. When about a year ago he showed his contact plug to some of the members, Professor Forbes at once suggested that this would form an excellent safeguard against a leak from the primary to the secondary circuit in a transformer. One side of the plug would be connected to any point of the secondary circuit, and the other would be connected to earth. As long as the potential in the secondary circuit remains within reasonable limits, this circuit would remain insulated from earth; but as soon as the potential increased owing to a leak from the primary circuit, the plug would act and put the secondary circuit to earth, so as to prevent all danger to persons touching it.



Mr. Atkinson criticised the Kingdon alternate current dynamo, which seemed to be very large for its output, and the arrangement of armature and field cores on the same yoke would probably throw a great strain upon the exciting dynamo, owing to the alternating electromotive force, which must necessarily be set up not only in the armature but also in the field coils. He thought that the advantage of using the armature as the fly wheel of the engine was only a theoretical one. Engine builders are very conservative, and object to the slightest alteration in their designs, and very few would be found willing to take off the fly wheel and put the armature of the Kingdon dynamo on instead. The advantage of being able to alter the coupling up of the armature coils whilst the machine is running is also illusory, since no person could be justified in allowing such work to be done when a high potential is on the wires. In experimental machines such devices are admissible; but now-a-days, when we know exactly what we require in the shape of potential and current, we can build the machine accordingly from the first, and need not make alterations after the machine is started. The adoption of iron in the cores of alternating current machines is certainly an improvement, but care must be taken not to saturate the iron to the same extent as with continuous current machines. The makers of multipolar disc machines have already found out that the core of the armature is much more liable to heat than with cylinder or drum machines, this being due to the more rapid and frequent charge of magnetism. Taking the figures given by the author for hysteresis as his starting point, he made a calculation to find what would be the permissible limit of induction in a sixteen pole alternate current machine running at 600 revolutions per minute, if the heat generated in the armature core is not to exceed that generated in a six pole continuous current machine running at the same speed. Taking fourteen lines (the author's measurement) per square inch in the one case, he found that only nine lines could be allowed in the other case, and this is about the induction in a machine, of which he exhibited a large photograph, and which was designed by Mr. Kapp and made by Messrs. Goolden and Co., of Halifax. The machine gave a current of 30 ampères at a pressure of 2000 volts, the speed being 600 revolutions, and the total weight 2½ tons. The armature is of the disc pattern, made partly of iron ribbon and partly of iron wire, and the copper coils are held in place by gun metal chairs so as to resist the mechanical strain brought upon them by the current. The value of these fastenings has, during a recent test, been demonstrated when the machine was accidentally short circuited pulling up the engine, without, however, moving a single wire on the armature.

Dr. Fleming gave the result of some experiments made at the Inventions Exhibition with two Zipernowski transformers, which were fed from a Ganz self exerting alternate current dynamo, at a potential of about 1000 volts. He and Mr. Zipernowski then used a wattmeter specially constructed for the purpose, the movable coil of which was about 2ft. high, and coupled in series with a non-inductive resistance. The results were, however, not satisfactory. At small loads the efficiency was found very much less than it ought to have been, which was, no doubt, due to the imperfect method of measuring, whilst at high loads the efficiency was probably ascertained with fair accuracy, the maximum being 92·2 per cent. Regarding magnetic lag, the speaker thought that this subject required careful investigation. He had no doubt in his own mind that magnetic lag was a reality, and he suggested to call it magnetic impedence, being a property of the magnetic circuit analogous to impedence on an electric circuit. He thought that experiments should be made to find the permeability curves of iron at different periodicities. He also sketched on the black board a proposed arrangement for interrupting connection between the lamp circuit and the transformer, in case potential difference between the secondary terminals should rise beyond a certain limit. This arrangement consists virtually of a double pole switch, held close by a fuse wire, which is electrically connected to the two mains. On the other side of the switch is a spring, tending to pull it open, and if upon a rise of pressure in the mains the wire fuses, the spring will pull open the switch, and thus interrupt the current at both mains. The discussion was adjourned until the 23rd inst.

MAIN SWITCH FOR ELECTRIC RAILWAYS.

Our illustration represents a main switch for electric railways, manufactured by the United Electrical Engineering Company, Albert Embankment, London. The great difficulty met with in switches for electric traction work is that of excessive sparking. This is due not only to the large power which has to be transmitted through the switch, but chiefly to the fact that the circuit necessarily has much self induction. When an electric current is used only for lighting, the self induction is comparatively small, and may, in the case of glow lamp installations, be quite negligible. A fairly strong lighting current may therefore be interrupted by a switch of ordinary construction without excessive sparking; but when the current is used to operate an electromotor in which the self induction of the field magnets and armature is considerable, a heavy flash is produced upon breaking the circuit. It is, of course, impossible to entirely avoid sparking with any construction of switch, and the only advantage which the designer of a switch can employ is that of letting the spark be produced in a place where it is not injurious. In other

words, the spark must not be allowed to take place between the working contacts of the switch, but between special sparking pieces which may be easily replaced. Such sparking pieces are now also put on the better class of electric light switches, where they are of metal; but in the switch we illustrate the sparking pieces consist of short and stout carbon pencils. We may mention that, some years ago, Messrs. Siemens introduced a switch designed on the same principle; in this the connection was first broken by the working contacts on the face of the switch, and afterwards between two carbon pencils behind the face. Switches for electric tram cars or railways must be designed to permit of the breaking of a considerably larger current than that nominally required to work the car. When first starting the car, the current is necessarily in excess of its normal value, and if, a few seconds after starting, it should be required to switch off, the switch must be able to break this excess current without being injured. The switch we illustrate is intended to break a current of 200 ampères flowing under a potential difference of 300 volts. The face of the switch board is of slate, set in a cast iron frame about 2ft. by 3ft., and there are five contacts on the face, four of them with terminals at the back, which take the leads to the artificial resistances in the usual way. The switch lever is pivoted at the bottom and provided with a spring catch and segment similar in construction to that used on locomotives. About the middle of the lever there is an insulated piece forming one pole of the switch. This piece is in connection with the metal contact piece behind the lever, but in front of the face of the board, and with a carbon pencil behind the board, the metal stud which carries the carbon holder passing through the segmental slot shown in our illustration. At the back of each of the four contacts is another carbon holder, and the carbons are so set that the carbon on the lever cannot pass them without deflecting each through a certain arc, a spring attachment on each carbon holder being provided to bring it back to the radial position after the lever has passed. By this means the break on the back of the board occurs after the working contacts on the face have already been separated. The switch board is intended to be fixed on the front platform to the right of the driver, so that he may work the lever with his right hand, as is done on locomotives.

COX-WALKER'S TELEMETER.

A telemeter is an apparatus by means of which the slow movement of the revolving hands of any indicating instrument in one place may be reproduced at a distant place by the movement of a similar hand, thus conveying the indications of the primary apparatus to one or more recording dials conveniently situated for inspection. Various instruments of this kind, in which electricity is applied as the transmitting agent, have from time to time been invented; but the difficulty has always been with the contacts. These should be absolute and positive, so as to insure a current of the right strength to be sent to the distant recording dial, and they should also be definite. The number of steps made by the hand on the receiving instrument should be exactly the same, and in the same direction, as those of the hand on the sending instrument, and for this reason it is absolutely necessary to prevent double contacts by jarring or other irregularities in the sending instrument. An ingenious device fulfilling these conditions was brought before the British Association meeting at Manchester last year, by Mr. F. R. Upton. This paper was descriptive of Mr. C. L. Clarke's telemeter system, and a reprint of it will be found in our issue of the 30th September last. Mr. Clarke's system is applicable not only for transmitting the movement of a wheel slowly revolved by mechanical means, but even for transmitting the small movement of the needle of a metallic thermometer, pressure gauge, or other delicate instrument. It has, however, the drawback of being somewhat complicated, and for the transmission of slow movements produced mechanically, the telemeter recently devised by Messrs. Cox-Walker & Co., of Darlington, seems preferable, on account of the greater simplicity and strength of its working parts. This apparatus has been specially designed for recording the water level at the bottom of a mine on a dial placed at the surface, and its construction will be readily understood from our illustration. At any convenient spot at the bottom of the mine is fixed the sending instrument (Fig. 1), consisting of a

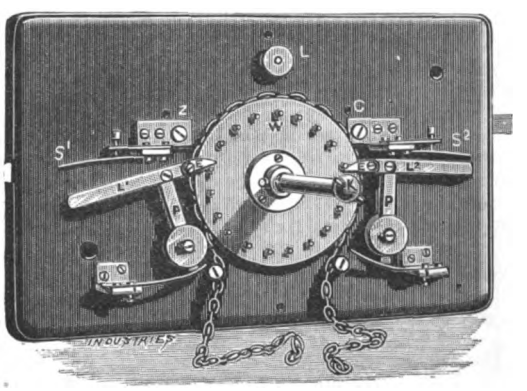

Fig. 1.

chain wheel W with pegs on its face, revolving on a stud set on a board. One end of the chain, which passes round its grooved circumference, is provided with a float, and the other is counterweighted. Where the locality does not admit of this board being fixed vertically over the well, a similar wheel can be fixed in that position, and its axis coupled with that of the wheel W by means of the universal joint K. To the right and left of this wheel W are fixed levers L^1 L^2, having spring catches E at their short ends, and counterweighted arms P at right angles. If the wheel be slowly revolved from left to right, the pegs as they strike the spring catches of the lever L^2 simply depress them, without producing any movement of the lever; but on the left side, when striking the spring catches from underneath, they raise the short end of the lever and deflect the counterweight to the right, as shown, until the pin has passed the end of the catch. The lever, now released, swings back, and its long arm strikes with considerable force the spring S^1, electrically connected to the terminal Z. If the movement is from right to left, the lever L^1 remains at rest, and the lever L^2 is similarly swung back each time that a peg has passed the spring catch, making contact with the spring S^2, which is electrically connected to the terminal C. The springs below the counterweights have no electrical function, and serve merely to steady the back swing of the levers. On the same board is a terminal L, which is electrically connected to both pivots on which the levers oscillate. Near this board is placed an ordinary battery, the zinc pole of which is connected to the terminal marked Z, and the carbon or copper pole to the terminal marked C. The

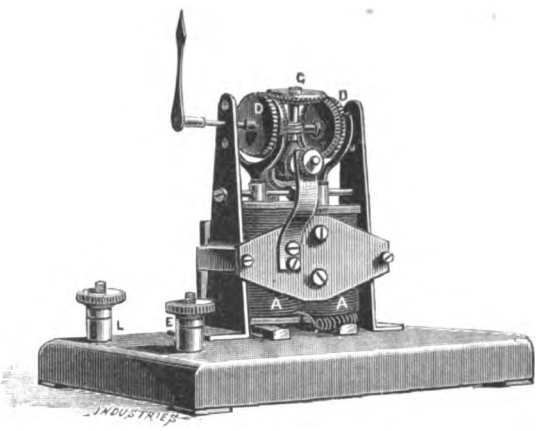

Fig. 2.

centre of the battery is connected to earth. From the terminal L there goes a single line wire to the surface, where it is connected to one terminal of the recording apparatus, which we shall presently describe, whilst the other terminal of this apparatus is connected to earth. It will now be clear that at each contact only half the battery is at work, sending either a negative or positive current to the line, according to which lever has touched its contact spring, and this negative or positive current produces either a forward or backward step on the recording apparatus. Certainty of contact is insured by the

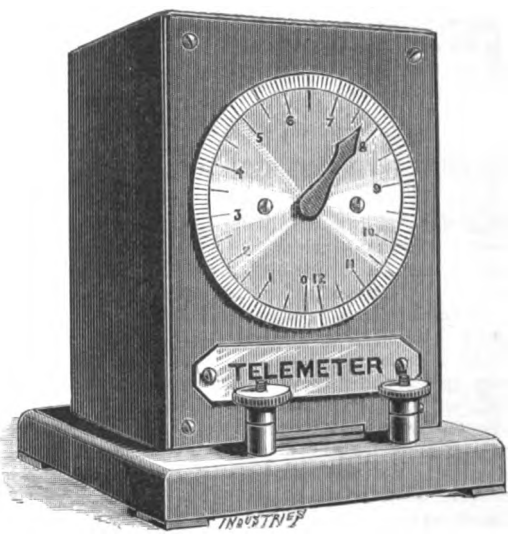

Fig. 3.

energetic movement of the counterweight, and the contact surfaces are kept clean by the slight scraping which takes place at each contact. The receiving instrument is shown in Fig. 2, with the case removed so as to render the mechanism visible, whilst Fig. 3 shows the appearance of the instrument when in actual use. As already mentioned, the line wire is connected to terminal L, whilst terminal E is connected to earth. The current passes through both coils of the electromagnet A A, and imparts movement in one direction or the other (according to its sign) to an armature polarised by means of permanent magnets, which are fixed in the base of the instrument. The armature carries driving anchors, which separately engage with the ratchet wheels D D, having teeth in opposite directions. The cores and anchors are kept permanently in position by means of spiral springs. The ratchet wheels impart movement to bevel wheels, into which gears a third bevel wheel C, forming a combination familiarly known by the name of "jack-in-the-box." The movement of the axis of the wheel C is reproduced by the pointer at the end of the spindle. It will be clear that the pointer only records the differential movement of the ratchet wheels, or, in other words, the algebraic sum of electrical impulses received. Thus, if positive and negative currents alternate, the pointer

FRIERN BARNET SEWAGE WORKS.

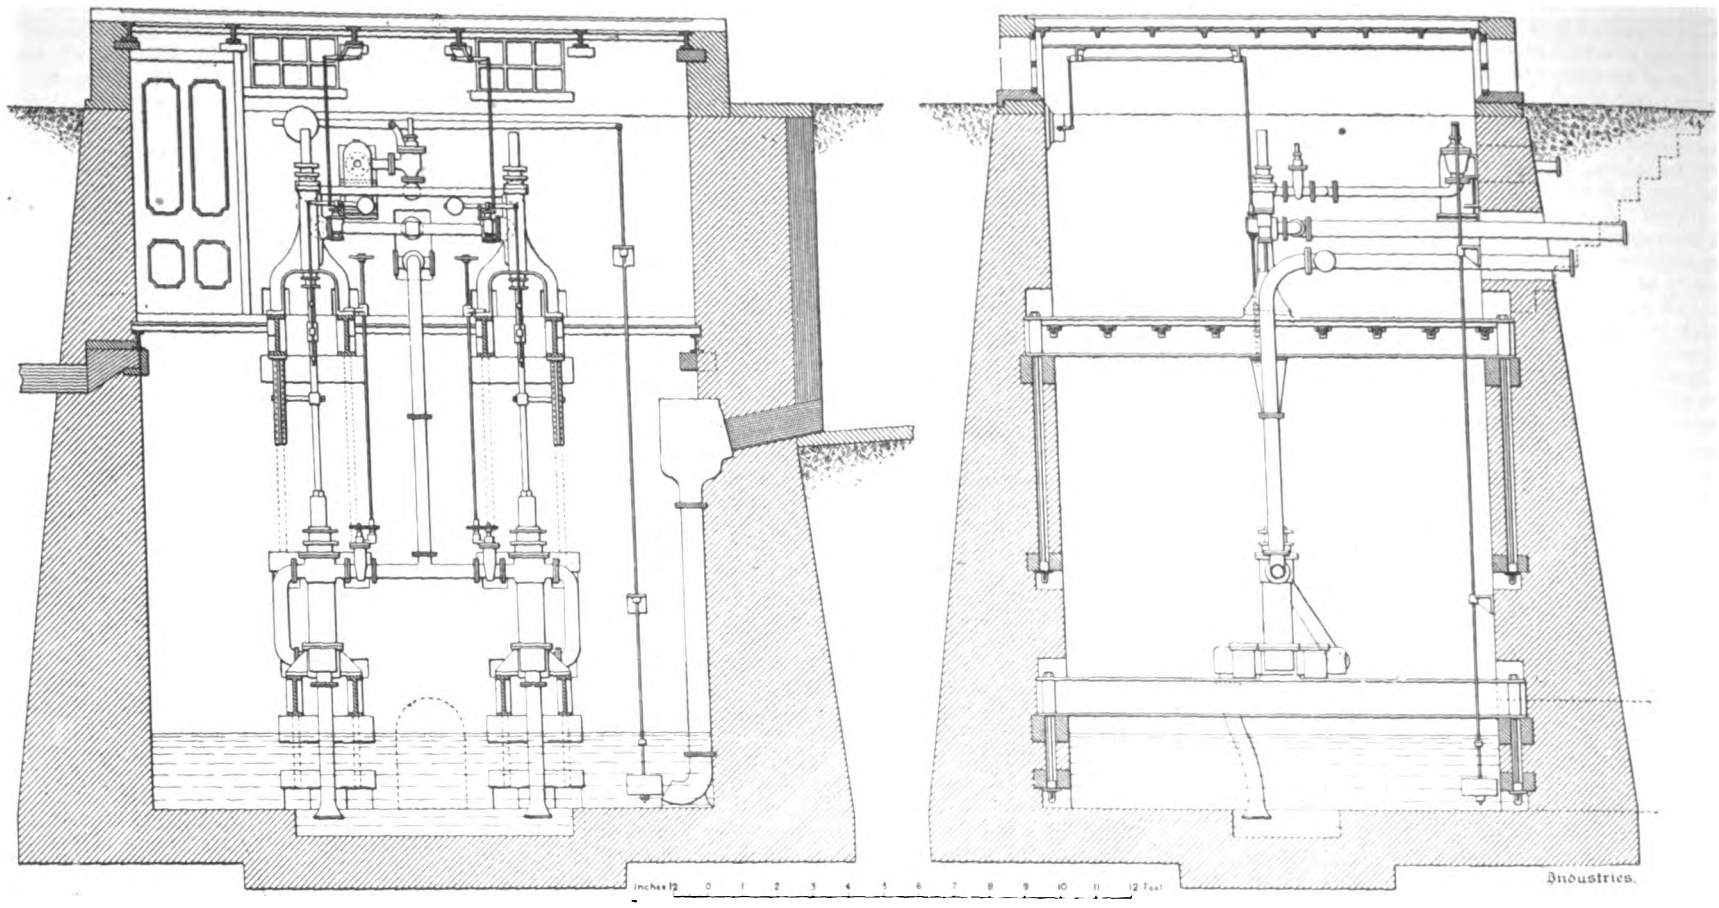

FIG. 1. FIG. 2.

remains at rest; but if one kind predominates over the other, the pointer will move, indicating the difference. By suitably dividing the dial, the recording instrument may thus be made to indicate the level of water in a distant mine, dock, harbour, or reservoir, as the case may be.

FRIERN BARNET SEWAGE WORKS.

WHERE there is no natural and immediate outlet for the sewage into a large river or into the sea, the drainage of small areas and the disposal of the products are problems which have exercised for some time past the powers of Local Boards in all parts of the kingdom. The difficulties of the problem are enhanced when the area to be drained is practically level, or when one part is considerably below the rest, so that continuous suitable gradients cannot be obtained to allow the sewage to gravitate to one main station. In drainage schemes for large areas, main stations can be erected at intervals, and steam engines and pumps employed to raise the sewage from one station to the next. In small areas, however, it would be too costly to employ steam engines and pumps at each station with the necessary staff for working them, and the question therefore arises, how shall the sewage be lifted from one point to another in order that it may gravitate to the central or main station? Such a question had to be decided by the Local Board of Friern Barnet, one of the suburban districts of North London. The Board had to drain 1304 acres which could be done by gravitation to one main station; but the difficulty was how to drain, in addition, low lying area in the Finchley district of 28·5 acres, about a mile distant from the main station. At present about five acres of the low level area are closely built upon, and the lift of sewage without allowing for friction is 47½ft., or with friction about 54ft. from the bottom of the tank at Ely Place to the invert of the high level sewer. Acting under the advice of their engineer, Mr. Baldwin Latham, M.Inst.C.E., the Board decided to employ in the low lying district hydraulic power for pumping the sewage up to the main station. The machinery adopted for this work is in principle the same as that applied by Mr. H. Davey for pumping in mines.

Before describing Mr. Davey's system of water pressure engines and pumps, we will give a brief sketch of the method of treating the sewage at Friern Barnet. As indicated above, the whole of the sewage is ultimately brought to one main station, where the Local Board have purchased about twenty acres of land, at a cost of £300 per acre. The larger portion of this land will be employed for tillage purposes, about two acres is used for filter beds, and another two acres for settling tanks, the buildings for the engines and machinery, and other necessaries for the chemical treatment of the sewage. The sewage is received at the main station in a fairly diluted state, and is conducted to a large revolving sieve or extractor wheel, where the solid parts are separated and fall into a receptacle fixed below the centre of the wheel, from whence they are lifted by an archimedean screw to a height sufficient to allow a trolley to be run under the outlet to catch them. When the trolley is full it is run off on tram lines, and another trolley substituted in its place; sufficient powdered lime is added in the trolley to thoroughly deodorise the solids, which, however, do not amount to much compared with the volume of sewage received. The sieves of the extractor wheel are kept clear from choking by a series of oscillating jets of water acting upon them. The sewage as received is slightly alkaline, and immediately after passing the extractor wheel it is rendered more alkaline by the addition of lime and water previously mixed in a special mixer. The sewage then flows on to a breast wheel, which acts as a most efficient mixer, and at the same time provides motive power for driving the extractor wheel and the distributors of chemicals (the lime already mentioned and sulphate of alumina). The distributors are small horizontal cylinders with a piston working in each, the cylinders and piston being of vulcanite to resist the action of the chemicals, and the connections consist of earthenware cocks and lead piping. The distributors measure out definite quantities of chemicals, lime water on one side of the water wheel, and water and sulphate of alumina on the other. The sewage now rendered neutral flows on at a lower level, through a kind of salmon ladder, by which it is turned about from side to side, and the chemicals are thoroughly mixed with it. It next passes on to the settling tanks (of which there are three), built of brick work, each tank being divided into two by a cross wall. Here the thick sediment settles, and the surface water is drawn off and filters through coke, once downward and once upward, flowing onwards in thin sheets (so as to present as much surface as possible for oxidation) into the channels, which conduct it to four filter beds occupying nearly two acres. Here the effluent is filtered through 6ft. of filtering material, comprising: First, 6in. of soil (a sandy loam); secondly 3ft. of fine ballast and soil; and thirdly, the bottom layer, 2ft. 6in. of rough ballast, consisting of pieces of burnt clay about 1 cub. in. each. The effluent is allowed to stand from two to three days, according to its state, to deposit any sediment that has not been deposited in the settling tanks. It is then permitted to filter through the beds and flow off to a natural stream. The clear and sparkling water flowing over the weir into the stream presents a striking contrast to the same liquid in the settling tanks. On the occasion of our visit the water of the stream below the outfall was decidedly clearer than the same stream a few yards above the outfall. When a glass full of the effluent water flowing into the stream is examined and held up to the light, it is seen to be perfectly clear, and free from the slightest odour, thus proving that the deodorisation has been complete.

To return, however, to the settling tanks. When the surface water is drained away to the extent of two-thirds of the depth of the tank, the remaining sludge is conducted by channels from the bottom of the tanks to a sump just outside the machinery house. We may remark that the tanks slope to the centre, where a semi-circular channel permits the whole tank to be completely emptied. From the sump the sludge is pumped up by two of Murray's chain pumps into a sludge well, where it is mixed with lime. From here it is pumped by three-throw hydraulic pumps (of which there are two sets), at a pressure of 100lb. per square inch, into filter presses, where the liquid is forced out, flowing back to the incoming sewage, to again go through the same cycle of operations, whilst the solid portion is retained in the filter bags in a plastic state. These cakes from the filter presses are sold as manure, or employed upon the land which will be farmed by the Local Board. The filter presses are supplied by Messrs. Johnson & Co., of Stratford, E.

In addition to the machinery mentioned for treating the sewage, there are three mortar mills, one for grinding the lime for the sludge well, one for grinding the lime for the incoming sewage, and the third for grinding the sulphate of alumina. There are also four mixing tanks, two for lime, and two for sulphate of alumina. The machinery is all driven by leather belts from a line of main shafting, which is driven by a pair of 14 h.p. horizontal engines, with expansion valves working on the back of ordinary slide valves. Each engine is capable of working independently of the other. Two Cornish boilers supply steam for the engines. The coke we have referred to as having been used for filtering purposes is burnt in the furnaces of the boilers. The contract for the sewage works has been carried out by Messrs. Thos. Vernon & Co., of Worcester and London, at a cost of £8,000 to £9,000. The buildings are conveniently arranged for the engines, boilers, and machinery, and the whole forms one of the most compact works we have seen.

The special novelty at Friern Barnet is the application of Mr. H. Davey's system of pumping at a distance from the motive power, by means of hydraulic pressure derived from an accumulator at the main station; the starting

Digitized by Google

and stopping of the pumps being automatic, thereby dispensing with the services of an attendant. The illustrations give two views of these automatic hydraulic pumps, from the design of Mr. H. Davey. They have been fixed at Friern Barnet for raising the sewage of the low level district to the main disinfecting station already described. The pumps are fixed in a well, into which the sewage flows by gravitation through the culvert shown dotted in Fig. 1. The surface water of the immediate neighbourhood drains into the same well by the pipe shown on the right of the figure. Fig. 2 is a section at right angles to Fig. 1, showing another elevation of the engines and pumps. As will be seen, the well is divided into two storeys by a floor carried upon iron girders. The water pressure engines are fixed at the level of the floor upon strong cast iron girders, built at the ends into the masonry forming the sides of the chamber, and placed directly below the water pressure engines are the pumps which lift the sewage. These pumps are also bolted to strong cast iron girders built into the walls of the chamber, both sets of girders being anchored securely by holding down bolts as shown. The pumps are automatically started by the float shown. When the sewage rises in the well above a certain level, the float is lifted, and, acting through a connecting rod, lifts one end of a starting lever, to which the main valve is attached. Directly the valve is lifted, water, at a pressure of 300lb. per square inch, is admitted to the water pressure engines through the top row of pipes, and the engines start. The pumps, which are connected to the piston rods, begin to lift, and continue working until the sewage falls below the starting level. The second or middle row of horizontal pipes takes off the exhaust water from the engines, which is discharged into a flushing tank at a distance, and employed for flushing the sewers automatically by means of a syphon. This arrangement saves the Local Board the cost of purchasing water from the water works at a cost of 1s. 3d. per 1000 gallons. The water used for working the water pressure engines is the effluent from the filter beds. The lower line of pipes is the rising main common to both pumps, and which conducts the sewage to the main station. Each engine and pump is capable of being worked singly, or they can work together, suitable valve arrangements being provided for this purpose. The pumps are double acting, of the ram and piston type, the ram being 5¾in. diam., and the piston 8in. diam. The water pressure cylinder is 3¾in. diam.; but the area upon which the pressure acts is reduced by a rod or ram passing through a stuffing box 3in. diam. on the top, and a piston rod 1¾in. diam. on the bottom, the extra total pressure on the upward stroke being required for lifting the weight of the moving parts. The stroke of both engines and pumps is 18in. The small rods and levers seen at the top are provided for driving indicators recording the number of strokes made by the engines. Each pump, when working at ten strokes per minute, lifts 100,000 gallons per day. The chamber is mostly underground, the roof being but a few feet above the ground level, and access is obtained to the machinery by a flight of steps shown in dotted lines in Fig. 2. The accumulator at the main station has a ram 12in. diam. by 6ft. stroke, and is lifted by a pair of pressure pumps driven by belts from the main line of shafting, each pump being independent of the other. When the accumulator rises to its full height it strikes a tappet and lifts a relief valve, thus stopping the action of the pumps, and notifying to the engine attendant that the pumps may be thrown off. The whole arrangement of the hydraulic gear has been well thought out, and it does its work efficiently. At the recent visit of the Margate Corporation, referred to in our impression of the 23rd December last, at which we were present, the machinery performed its work in a satisfactory manner.

DUTY FREE ALCOHOL.

At a recent meeting of the Society of Chemical Industry in Edinburgh, Mr. Dott drew attention to the serious disadvantages under which the British chemical manufacturer labours in not being able to obtain duty free alcohol, as in other countries. Not only pharmacists, but many manufacturing chemists require alcohol of pure quality for the successful production of many important preparations; and it has been found that methylated spirit fails in many respects to meet the wants of the chemical manufacturer. We some time ago referred to this question (see *Industries*, Vol. II., page 92). The preparation of most of the alkaloids, of chloral, chloroform, salicylic acid, and pharmaceutical tinctures cannot be undertaken in this country except at a considerable loss to the manufacturer, and consequently most of these and many other fine chemicals are imported into this country. The recent regulation of the Inland Revenue Board restricting the purchase of methylated spirit for use in any manufacture or industry from a licensed maker of the spirit, makes it still more difficult for manufacturers to obtain the substitute for absolute spirit, which they have hitherto been compelled to use. Efforts have been made within the last few months by a committee of the chemical section of the London Chamber of Commerce to induce the Excise to make certain concessions in the spirit duty to those who employ it for such manufacturing purposes. We understand that although British made tinctures are in general use in this country, few are exported, as the English manufacturer finds that he can buy in Hamburg and elsewhere abroad similar preparations which have been manufactured from duty free spirit, and exports them to our own colonies in the place of those which are made in this country. The committee referred to have been endeavouring to obtain a drawback on tinctures and other preparations in which alcohol forms an important constituent exported in bottles from this country, and we hope that the Revenue authorities will see their way to grant this concession. Even should this be granted, the British manufacturers will still be handicapped as compared with those on the Continent, as there is always a certain loss of spirit in the manufacture, and, therefore, a loss of duty, which cannot be recovered in the drawback. Mr. Dott, in his paper before the Society of Chemical Industry, suggested that the manufacture of chemicals in which alcohol is employed, should be conducted "in bond," and we hope that some such plan as this may be finally adopted. In Germany the Revenue authorities give special permission to manufacturers, and these exceptions have been found not to affect the revenue in any way, while at the same time it has given considerable encouragement to the development of new manufactures. The comparatively important industry of the manufacture of coal tar colours, of new febrifuges and antiseptics, is consequently almost entirely in the hands of the Germans. Fulminating mercury, to take another example, is not made to any large extent in this country, whereas on the Continent the manufacturers of this substance are allowed to use absolute alcohol to which a small quantity of turpentine or bone oil has been added, instead of the ordinary methylated alcohol or duty paid spirit. In the new German spirit law alcohol for use in medicinal and scientific purposes was declared exempt from its principal clauses, and remained free from the increase of duty until special concessions, such as those we have alluded to, could be made. In America, before the law relating to the use and manufacture of methylated spirit was passed, similar disadvantages were experienced by manufacturers; but their representations were not sufficient to cause the authorities to allow them the same privileges as have been obtained in Germany. The importance to this country of being able to compete with foreign countries in the manufacture of new chemical preparations is so obvious, that we are sure that the Inland Revenue will be willing to come to a satisfactory arrangement with the committee of the London Chamber of Commerce on this subject; and we hope that at the same time the question of the use of duty free alcohol by other manufacturers, and in institutions where chemistry is taught, or where scientific investigations are being conducted, will be considered, and that the proposals that these manufactures should be allowed to be carried on in bond will be acceded to.

Notes.

MINING IN SYRIA.

The mining interests of Syria are wholly neglected, and the United States Consul at Beyrout states that no exploration is being made of the iron, coal, lead, copper, or silver deposits which exist in that country. The bitumen mines in the Hasbeya district, which were very profitable for a number of years, have been abandoned, the contract with the Turkish Government having expired and the immediate supply being apparently exhausted. In the Latakia district a mine producing chromium has been opened up.

MINING IN COLOMBIA.

In the course of a general report upon the resources of the United States of Colombia, Consul Dickson, of Bogota, points out that this republic possesses rich mines of gold, silver, iron, copper, and lead. The total value of the precious metals produced in Colombia since its conquest by the Spaniards in the sixteenth century is estimated at £130,000,000. The production of gold from the beginning of the century up to 1884 amounted to £42,200,000, and of silver to £3,000,000. In almost every part of the country alluvial gold is to be found, and a circular issued by the Colombian Minister for Foreign Affairs states that foreigners can acquire mines on the same conditions as natives. It is therefore not unlikely, in view of the favour with which mining speculations are at the present looked upon by the investing public, that attention will be directed to this portion of South America by mining company promoters.

BELGIAN COMPETITION IN TURKEY.

Consul-General Blunt, of Salonica, in his report on the trade of that port during 1886, which has been delayed owing to his ill health, states that the total value of British goods imported was about £510,000, a falling off of £90,000, partly caused by low prices and partly by Belgian competition. He states that Belgian manufacturers continue to make headway at Salonica and the interior, owing to their cheapness and to the long credits allowed to the importers by Belgian firms; and that most of the metal goods, such as rails and railway fittings, girders and cast pipes, which used to be obtained from Great Britain, now come from Belgium.

FOREIGN PRODUCTION OF IRON AND STEEL.

At a meeting recently held in Glasgow for the reform of our fiscal system, Mr. Neilson, of Mossend, quoted some figures to show the relative production of iron and steel in Britain and foreign countries, which will be of interest to some of our readers. We therefore give some of them, although we do not express an opinion in the meantime on the deductions which were made from them. Taking first the production of pig iron during the past ten years, we find that in America, with its tariff of 28s. per ton, the production had been raised from 2,066,549 tons in 1877 to 5,075,485 tons in 1886, or an increase of 3,008,891 tons, equal to an increase of 145·59 per cent. Germany, with its tariff of 10s., in 1877 produced 1,421,667 tons, and in 1886 3,339,803 tons, or an increase of 1,918,136 tons, equal to 134·92 per cent. Belgium, with its tariff of 4s., in 1877 produced 470,888 tons, and in 1886 697,110 tons, an increase of 226,222 tons, equal to 48·04 per cent. Austria-Hungary, with its tariff of 8s. 9d., in 1877 produced 409,000 tons, and in 1886 620,000 tons, or an increase of 211,000 tons, equal to 51·59 per cent. Great Britain in 1877 produced 6,608,664 tons, and in 1886 6,870,665 tons, an increase of 262,001 tons, equal to 3·96 per cent. Thus the United States shows an increase of 145·59 per cent., Germany 134·92 per cent., Austria-Hungary 51·59 per cent., Belgium 48·04 per cent., and Great Britain 3·96 per cent. In Bessemer steel the United States produced 500,524 tons in 1877, while in 1886 they produced 2,026,062 tons, an increase of 1,525,538 tons, equal to 304·78 per cent. Germany in 1877 produced 391,110 tons, and in 1886 1,185,000 tons, an increase of 793,890 tons, equal to 202·98 per cent. Russia in 1877 produced 40,000 tons, and in 1886 270,000 tons, an increase of 230,000 tons, equal to 575 per cent. Great Britain in 1877 produced 750,000 tons, and in 1886 1,570,256 tons, an increase of 820,529 tons, equal to 109·43 per cent.

BRITISH FOREIGN TRADE.

A short time ago, Mr. J. W. Wells, C.E., in an address before the London Chamber of Commerce, took a very gloomy view of British trade, and showed by statistics that while our industries are decaying, those of foreign countries are on the increase, and some of the examples he quoted were striking enough. For instance, when railways were first laid down in South America, every railroad in Brazil, as elsewhere, was British throughout—capital, engineers, contractors, materials, rolling stock, and general principles of administration, were all British; and now one hears of a Brazilian railway built by Brazilian engineers and contractors, paid for with Brazilian capital; the locomotives and iron bridge work supplied by Americans, the cars by Germans, the rails by Belgians, the workshop machinery by French, and nothing English in the whole of the line. The Americans secured the order for locomotives and iron bridge work, not because they were less expensive than English work, but because they were of a type and character best adapted to the necessities of an economical railway in a semi-wild country. The Germans obtained the orders for the cars because they had adopted the American type, and turned them out at a less price than the Americans asked; while the rails and shop machinery were bought from France and Belgium because these goods were pushed by agents from those countries in a land where British manufacturers are practically unrepresented. The report of the British Vice-Consul at Venice refers to the energetic and successful competition of the German and French manufacturers with British exporters. British goods which were once in great demand, have been supplemented by German and French articles, and the Vice-Consul gives as the chief causes of this, the cheapness of French and German goods, which, although of much inferior quality, bear a certain appearance of being as good as the English; and further, that the French and Germans employ active commercial travellers, through whom they are accurately informed of the wants of buyers, and are prompt to adapt their supply to the nature of the demand; and finally, the long credit, generally three or six months, which is given by Continental exporters. It is so far satisfactory, however, to know that British goods still enjoy a high reputation for their workmanship and lasting qualities, and would certainly be given the preference by the buyers but for the great difference of price.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

10th February, 1888.

2008. Morris, H. ..... Railway signalling.
2011. Ashworth & Ashworth Carding engine.
2015. Hannay, J. B. ..... Signalling apparatus.
2016. Rankine, J., & others... Plates for furnaces.
2017. Gaskell, J. ..... Cranes.
2018. Bothams, J. C. ..... Armour for vessels of war.
2022. Frew, J. ..... Automatically preventing over-winding.
2024. Tordoff, J. H. ..... Furnace tubes.
2027. Harrison & Gilson..... Cartridge loading machinery.
2034. Cotsworth, G. G. ..... Pulleys and drums.
2038. Buchanan, A. ..... Punching apertures in plates.
2047. Watson, J. ..... Horticultural boilers.
2050. Lawrence, J. P. ..... Refrigerating apparatus.
2055. Jolibois & Bonsor..... Boiler furnaces.
2061. Long, H. S. ..... Knitting machines.
2062. Tolhurst & Oddie..... Furnaces.
2064. Kapteyn, A. P. ..... Automatic brake.
2065. Harston, C. G. ..... Cartridge magazines.
2068. Thatcher & Ritchie... Machinery for making envelopes.

11th February, 1888.

2074. Hollingworth, E..... Jacquard mechanism of looms (*Hutchins.*)
2075. Sauvée, A. ..... Carriage for quick-firing guns (*Canet*).
2076. Hearfield, J. W. ..... Friction pulleys.
2078. Schofield, W. ..... Boiler furnaces.
2080. Robinson, J., & others Rotary engines.
2081. Hill & Hill..... Saw sharpening machine.
2082. Baharie, J. T. ..... Lifeboat.
2083. Perrin, J. ..... Veneering felt hats.
2088. Gilchrist, J. G. ..... Dynamometers.
2089. Williams & Williams.. Automatic steam dryer.
2090. Gibson, J. ..... Obtaining power from railway trains.
2094. Cockshott & Jowett... Shaft couplings.
2100. Hutchison, J. ..... Type writing machines.
2106. Killin & Masson ..... Paper making.
2112. Appleby, H. ..... Blast pipes.
2114. Katz, R. ..... Double engine ploughing.
2116. Raworth, J. S. ..... Shaft couplings.
2117. Carson, J. ..... Seeding machine.
2118. Bayrer, W. J. ..... Shears for metal.
2121. Barter, A. ..... Coupling railway waggons.
2123. Dietz, H. ..... Pneumatic separator.
2124. Hodgkin & Hodgkin ... Steam and vacuum pumps.
2127. Aldridge, C. H. ..... Knitting machines.
2129. Heucke, A. ..... Ploughs.

13th February, 1888.

2132. Blacker, G. ..... Apparatus for raising water.
2133. Sturgeon, J. ..... Hydraulic hoists.
2134. Urquhart, W. W., and others ..... Cloth finishing machines.
2136. Woodward, E. M. ..... Running rolling stock from broad to narrow gauge.
2143. Hollingworth, E..... Jacquard mechanism in looms.
2145. Smith, W. R. W. ..... Consuming smoke.
2146. Flather, A. ..... Jacquard machines.
2148. Blamires, T. H. ..... Carding engines.
2149. McInnes, T. S., & others Engine indicators.
2150. McInnes, T. S. ..... Testing spiral springs.
2154. Martin, M., & others... Dressing hides.
2158. Moore & Wallwork... Manufacture of hats.
2165. Marshall, J. ..... Thrashing machines.
2166. Pieper, H. ..... Repeating fire arms.
2168. Worrall & Lawrence. Finishing cut pile fabrics.
2169. Gass, W. G. ..... Winding yarns or thread.
2172. Penrice, H. N. ..... Rock tunnelling.
2173. Aldridge, C. H. ..... Knitting machinery.
2175. Justice, P. M. ..... Spinning machines (*Metcalf*).
2176. Hill, J., & others ..... Railway signal apparatus. (Received 13th February, 1888. Ante-dated 25th January, 1888, under International Convention.)

14th February, 1888.

2184. Story, E. ..... Manufacture of glass.
2185. Askew, A. J. ..... Wringing & mangling machines.
2189. Williams, T. ..... Sewing machines.
2201. Kiddie, A. W. ..... Propulsion of small boats.
2203. Evans, R. ..... Cartridge chargers for machine guns.
2204. Simpson & Porter ..... Excavators.
2205. Pickles, J. ..... Looms.
2208. Scott, J. ..... Manufacture of paper.
2209. Smith & Fishwick ..... Looms.
2215. Newall, G. W. ..... Steam engines.
2216. Moyer & Youlls..... Car axle boxes.
2232. Wells & Pallett ..... Hot air motors.
2233. Downing, G. ..... Manufacturing buttons (*Scherding & Ruger.*)
2237. Logan, W. P. ..... Post anchors.
2238. Snelgrove, W. ..... Weighing machines.
2243. Claret, J. ..... Liquid meters.
2244. Essington, H. M..... Sewing machines.
2245. Husberg, N. G. K. ..... Propelling mechanism for vessels.
2247. Larivière, J. ..... Copper plate printing machines.
2249. Tuck, N. L. ..... Block printing oil cloths.
2252. Imray, O. ..... Duplex pumps (*Dow*).
2255. Martin, G. ..... Carding machinery.

15th February, 1888.

2265. Tweedale, S. ..... Carding engines.
2266. Platt & Fidler ..... Grinding the "flats" of carding engines.
2267. Smith, W. ..... Copying lathes.
2268-9. Crighton, J., & others. Fans for exhausting and propelling air.
2270. Burton, S. ..... Mules.
2271. Bleasdale & Hargraves ..... Steam engines.
2278. Schmidt, W. ..... Boiler feeding apparatus.
2279. Elliott, G. W. ..... Boring machines.
2281. Forknall, T. ..... Carding engines.
2283. Liversidge, H. ..... Steam engines.
2286. Bee, T. ..... Thrashing machines.
2294. Webley, T. W. ..... Ejector fire arms.
2295. Hunt, T. ..... Screw cutting rods.
2301. Muncaster, H. ..... Expansion gear.
2312. Vavasseur, J. ..... Moving guns on board ship.

16th February, 1888.

2321. Eke, R. J. ..... Spinning fibres.

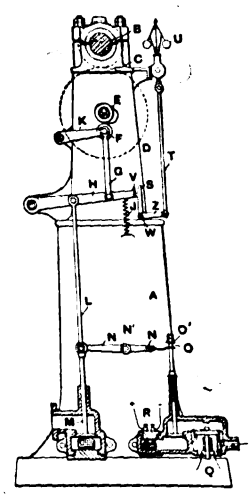
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Steam Boilers.—*J. A. Batley, London.*—In that class of boilers where steam is generated by passing the water through coils which are directly exposed to the heat of the furnace, it is found that the steam supply is too intermittent to afford a constant force for practical purposes. The object of this invention is to remedy this defect, and also to arrange a more efficient indicator of the pressure of the steam and water within the generator. The method pursued by the inventor will be understood by reference to the accompanying figure. The apparatus consists of three separate vessels, the boiler C, the water reservoir F, and a steam reservoir placed behind F, and connected with it by a pipe F^1. The water is forced by a pump into the vessel F, from whence it passes through the coils E E^1 E^2, and rises through them into the top of the chamber F. The steam which has been generated during the travel of the water, is led into the steam



chamber through the pipe F^1, where it forms a constant source of fluid pressure, while the water which has not been altered is allowed to fall to the bottom of F, where water again joins the supply. A gauge is placed in the vessel F, just below the opening F^1, to enable the attendant to ascertain the state of the water and steam within. The cylindrical portion of the casing C consists of two thicknesses of sheet metal, between which a non-conductor is interposed. Of the three coils E E^1 E^2, the coil E^1 contracts at its upper end to a diameter smaller than that of the innermost coil, and thereby presents an intense heat to the contained steam immediately before its passage out of the boiler. Above the coils a curtain H is situated, being supported by bolts hanging from the coned part of the casing. This curtain is formed of a slightly dished annular plate, with a flange L for the purpose of directing the flames and gases through the outermost coil into the chimney K when the damper J is closed. The furnace A consists of a cylindrical casting, resting on the bed plate A^1, and upon the same plate the fire bars G are carried. The coils are supported on the plate B, and, in order to facilitate their junction with the receiver F and to break up the lateral draught of the gases of combustion, the outermost and innermost are made in the form of a right handed helix, and the other one is laid in the reverse direction. The inventor makes two claims for this apparatus, designed to make the supply of steam constant.—No. 2967. February 25th, 1887. 8*d.*

Construction of Steel Beams.—*F. Pilkington, London.*—In order to strengthen a plain steel beam, and to render it more or less fire proof, the inventor uses angle iron or T iron supports. These irons are fixed to the girders in the usual way as in plate girders, and their ends are made to overlap and surround the flanges of the beam. In some cases the overlapping irons serve to keep a layer of fire proof material, such as concrete, in its position between the flanges of an I beam; and sometimes they serve to support a layer of concrete between the girder and the buttress on which the beam rests. The inventor makes three claims.—No. 15131. November 7th, 1887. 8*d.*

Traction Engine and Road Roller.—*S. Eddington & J. E. Steevenson, Chelmsford.*—The object of this invention is to construct a traction engine in such a way as to permit its conversion into a road roller at any time. In order to make the machine useful as a roller, the front pair of wheels must cover the same breadth of ground as is covered by the large wheels. The roller wheels are to be located in advance of the smoke box, so that rollers of any size may be used. In converting the machine into a roller, the front pair of wheels and the swivelling part of the fore carriage are removed, and they are replaced by a cantilever frame, which takes a bearing beneath the front part of the smoke box. The rear end of the frame is received in a socket fixed beneath the boiler; and the front end projects beyond the smoke box in the form of a horizontal ring frame, in which the roller wheels are mounted. The rear wheels of the traction engine are to be replaced by heavy roller wheels in the ordinary way. The inventors claim the application to a traction engine of roller wheels mounted so as to swivel about a vertical axis, in combination with a cantilever frame that takes an upward bearing beneath the front part of the boiler, and a downward bearing at a point in the rear, the roller wheels being situated in advance of the upward bearing.—No. 3463. March 7th, 1887. 8*d.*

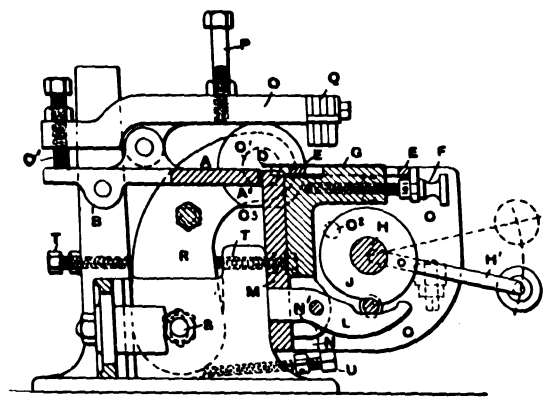
Gas Engines.—*E. Körting, Hanover.*—By this invention several improvements are introduced into that class of gas motors whose governor keeps the exhaust port open when the speed is too high. The first improvement consists of establishing a connection between the exhaust valve and the induction valve, whereby, when the exhaust valve is opened, the induction valve is kept closed for the purpose of preventing the entrance of the combustible mixture into the cylinder. The second improvement consists of new apparatus for keeping the exhaust port open when the speed is too high. An elevation of the proposed valve gear is shown in the accompanying diagram. On the crank shaft B is the wheel C, which gears with D. A cam E is fixed on the shaft driven by D; a lever K with a roller F, and the rods G H L N, and the spring I serve to transmit motion to the exhaust valve M and to the admission valve P. The valve Q serves to mix the gases and the air in definite proportions. The connection between the exhaust and admission port is

effected by means of the rocking lever N. One end of it slides in a slot in L, and the other end carries a spring which gears with the nut O^1. When the valve M is fully open the valve P will be pressed against its seat. The cam plate E during its revolution causes the rods G and L to move downwards intermittently. That motion opens the exhaust port M and closes the admission port P. A pawl S Z, with its fulcrum at W, is connected to the rod T and the governor U. When the rod T is drawn up to a certain position by the governor the pawl S catches the end V of the arm H, and prevents the spring I from restoring H to its former position after its depression by the cam E. The exhaust port is thus kept open altogether and the admission port is closed, so that the piston pushes the combustion gases to and fro without being able to draw any more combustible gases through the valve P. When the speed of the engine is sufficiently diminished the pawl is withdrawn from the catch V, and the usual series of operations are proceeded with. The inventor makes two claims: (1) For the combination of the apparatus N O with the valves M and P, and (2) for the method of connecting the governor with the exhaust and induction valves.—No. 5981. April 25th, 1887. 8*d.*

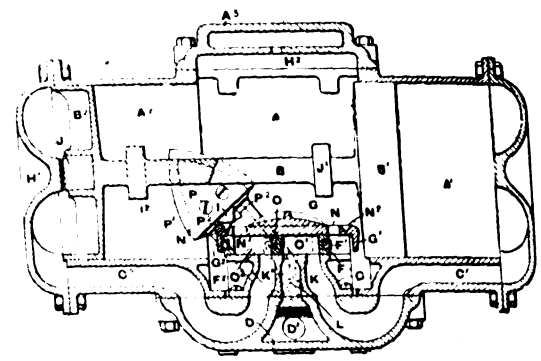
Slide Valves.—*T. J. Simmons, London.*—This invention relates to the slide valves of compound engines, and it consists of a new construction of the valve, with the object of reducing the amount of heat wasted while the steam passes from one cylinder to the other. The valve is made in a hollow tubular form, and has two sets of ports on each side, to correspond with a similar series in the sides of the valve chambers. The disposition of the valve chambers and the valves will be seen by reference to the annexed diagram. The steam issuing from



either end of the high pressure cylinder C passes along the duct K, and escapes in the direction of the arrow through the open ports of the valve A into the supply passage of the second cylinder. The same process takes place when the steam is exhausted from the second cylinder. The inventor makes three claims for the construction of the hollow tubular valve with ports in its sides to correspond with similar ports in the valve chambers, for the purpose described.—No. 3900. March 15th, 1887. 8*d.*

Wood Planing Machines.—*J. C. Humphreys, Braxton, Virginia, U.S.A.*—This invention involves a new and improved construction for the cutter bars used in wood planing machines. The knives are of a convex shape, and are fitted eccentrically on the bars; the number of knives is preferably three on each bar, mounted equidistantly from each other. They extend half the length of the bar, and the set of knives on the other half of the bar are arranged in the same way, with their edges advanced one-sixth of a revolution round the circumference of the bar. In this way the knives on the two parts come alternately into action on the wood, and the great strain on the bands and driving gear is thus diminished. The knives may be set at an angle of 15° with the wood, so that their action on the wood is more of the nature of planing than in many machines of the kind. The inventor makes three claims for the arrangement of the two different sets of three convex knives, as described.—No. 17040. December 10th, 1887. 8*d.*

Pulverising Machinery.—*E. Wilson, Exeter.*—The case of the improved machine is in the form of a short cylinder, with its axis horizontal, and mounted on suitable supporting frame work. The cylindrical surface consists of a gauze wire work, which allows the pulverised material to escape through it when sufficiently disintegrated. The two ends of the case are provided with iron ribs, which run radially part of the way, and then turn in a different direction. The beaters are mounted on an axle, which passes through the axis of the cylinder, and the ribs are placed so as to approach the beaters as near as is consistent with utility. A hopper is fixed to one side, and it feeds the material into the centre of the cylinder. The centrifugal force of the beaters throws the material against the ribs and the cylindrical surface of the case. Part of the material goes through the gauze, and the remainder falls down once more towards the centre, whence it is again thrown with great concussion against the ribs and the gauze until the pulverisation is complete. The inventor makes three claims, for the construction of the case, for the ribs, and for the method of mounting the beaters on the axle.—No. 3443. March 7th, 1887. 8*d.*



Metal Folding Machine.—*S. Stevens, London.*—This machine is intended for bending metal plates at any desired angle, and provision is made for adjustment in case of wear or of alteration in the work. The accompanying diagram represents a section of the machine taken at right angles to its length. The table A is pivoted at B to the supporting standards, and the frame C C^1 is fixed to supports which enable it to rotate round the axis D. The regulator frame E is capable of being adjusted according to the required width of the bend by means of the set screw F, and the knife G is placed with its edge coinciding with the axis of oscillation of the frame C. The shaft H may be partially rotated by the handle H^1, upon which the cam J is keyed. The motion of this cam acts on the lever jaws L, and raises the gripper plate M, which grips the metal plate between itself and the edge of the knife G. The whole frame C rotates about D as an axis, and in so doing bends the plate, because the table A prevents its

rotation with the frame. Just before the frame arrives at the end of its oscillation, the flat C^2 comes uppermost, and allows the lever O to fall; the table, no longer held up by the stud O^1, also falls, and the plate may be removed. During the latter portion of the rotation of C, its weight rests on the handle H^1 in such a direction as to cause the shaft H to return to its normal position; the cam J follows with the shaft, and thus the lever L is unlocked. The surface N^1 of the lug N, which is fixed on the gripper M, comes to rest upon the stud P. This action removes the gripper from the knife, and the plate may be removed. If a small amount of bend is required, the pins C^2 on each cheek of the frame C are made to come in contact with one of the adjusting pieces Q. As shown in the drawing, the pieces would allow the pin to clear and complete half a revolution; but if they are turned so as to rest in a horizontal position, they project into the path of the pin, and so prevent the further motion of C. If they are all placed horizontally, the plate will be bent at right angles. In case the knife or the edge of the table wears, the adjustment may be effected as follows: The axis D is pivoted on the brackets R, which are pivoted at S; by moving these brackets to the right or to the left by means of the set screws T, the frame C may be caused to recede from or approach the edge of the table A. Should the table A be not parallel to the knife, either end may be raised or lowered by the set screws U. The inventor makes four claims for the combination of rotating table and gripping jaws as described, and for the means of its adjustment.—No. 1878. February 7th, 1887. 8*d.*

Boiler Furnaces.—*R. Marshall, London.*—The air is made to pass in thin strata immediately beneath the under side of the fire bars, so that it becomes heated by radiation before coming in contact with the fuel. The combustion in the furnace is thus rendered more perfect, and a higher efficiency is obtained. For this purpose a plate is fixed underneath the bars, and the air in passing to the furnace has to travel some distance towards the inner end of the fire box before it can turn the corner of the plate and rise up to the bars. Doors are arranged in the outside casing of the furnace for the insertion of tools, in order to clear the plate of ashes. The plate may also be made of folding or swinging blades, and the ashes are then caused to fall off by turning the plate on its hinges by a handle outside. A jet of steam is preferably employed to accelerate the current of air between the plate and the bars. In cases where the furnace is contained in an internal flue of the boiler, the fire grate is brought down lower so as to leave very little space between it and the flue; the same object is attained by this arrangement. The inventor makes four claims.—No. 4601. March 28th, 1887. 8*d.*

Water Meters.—*M. P. Freeman, Somerville, Massachusetts.*—A longitudinal section of the meter, constructed according to this invention, is shown in the accompanying figure. The shell of the meter is divided into three portions—A A^1 A^2. The first of these is in connection with the water supply through the opening H^2, and the latter two are the measuring cylinders. The two pistons B^1 B^2 are connected by the rod B, on which are fitted the collars J^1 J^2. The yielding bunters J are sunk into the pistons, in order to minimise the force of the collision between piston and cylinder at the end of each stroke. The valve mechanism consists of the ports K K^1, and of the exhaust port L, which communicates with the delivery pipe D^1. The cover G, with its projecting lips G^1 G^2, is supported by standards

not shown; and between G and the valve surface is the slide valve F, which is caused to reciprocate by a rack gearing with the toothed sector shown in the diagram. The valve F has the two passages O^1 O^2 in it, and pads are fitted at its ends similar to those on the pistons. The cover G has holes N^1 N^2 in it, which allow the passage of water through them. The motions of the pistons and the valve are connected by means of the weighted lever I, which is hinged at the bottom. The head of this lever leans against the collars on the piston rod B, and rocks in the plane of the figure. The action of the parts is as follows: When the position of the mechanism is as shown in the figure, the water is admitted into A, and passes through the opening N^1 in the cover G, and round the lip G^2, through the valve opening O^2, through K^1 C^2, to the rear of the piston B^2. The pistons then move to the right, and the liquid which was in A^1 is forced through C^1 K O^1 L, and through the delivery pipe D^1. As the pistons move on the collar, J^2 comes in contact with the periphery P^1 of the lever I, which is thus swung round its hinge. When the lever has gone a little beyond its central position, some pins which it carries come in contact with the toothed sector; the motion of this sector carries the valve F along with it, and causes it to assume a similar position with respect to the passage K as it did before with the passage K^1. The weight of the lever is then sufficient to cause the collar J^1 to travel on to the right. In order to deaden the blow of the lever I against the cover G, the elastic projections P^2 are placed on I, and dash pots N^2 are hollowed out in the cover G to receive them. The action of the meter is then reversed, and the same train of operations re-commences. The inventor makes six claims for this arrangement of weighted lever and the slide valve.—No. 16433. November 29th, 1887. 8*d.*

Pulverising Machinery.—*J. R. Alsing, London.*—The cylinders are constructed of blocks or plates, and the object is to provide a simple means of joining these parts together. The circumferential plates are grooved along one edge and ribbed along the opposite edge, so that the grooves and ridges of adjacent plates shall fit into each other. The sectorial plates at the ends of the cylinders are fitted in the same way. The whole cylinder is held together in a frame, and is employed for the usual purposes. The plates may be of iron or steel, and are adapted to either wet or dry grinding. The inventor makes three claims for these improvements.—No. 5379. April 13th, 1887. 6*d.*

Valve Gear for Steam Hammers.—*A. Davy & W. J. Benton, Sheffield.*—The object of this invention is to cause the hammer to fall dead on the anvil instead of giving the usual elastic blow. The descent of the hammer is actuated by steam, but the distributing valve is disconnected from the hammer head during its fall, and is moved by an independent means, such as a spring. A cataract cylinder is placed between the spindle of the distributing valve and the gear on the hammer head which controls the motion of the distributing valve. The effect is that the downward stroke does not terminate in an elastic spring, but the hammer slackens speed and pauses slightly. The inventors make one claim for the combination of the cataract with the distributing valve, for the purpose described.—No. 4066. March 17th, 1887. 8*d.*

Paper Making.—*L. McFarlane, St. Mary Cray, Kent.*—The inventor has designed a machine for taking the glazed paper from the set of glazing plates, and for filling the set with paper ready to be placed in the calenders. These processes have hitherto been effected by hand. A tubular standard passes upwards, above and between a series of platforms which are adjustable to be raised or lowered. The standard carries three tubular arms, which are provided with india-rubber suckers, and is connected with an exhaust fan, which produces the vacuum utilised for sucking up the paper and plates. A rotary motion is communicated to the standard and the arms. Valves are provided in the arms in order to introduce the vacuum into them intermittently, thereby enabling the arm to pick up or release the paper according to the arrangement of the working of the machine. A mechanism is also designed for lowering the platforms as the height of the pile of paper decreases. The inventor makes five claims for this new machine, and for the application of the tubular arms, and the vacuum, for the purpose described.—No. 910. January 6th, 1887. 8*d.*

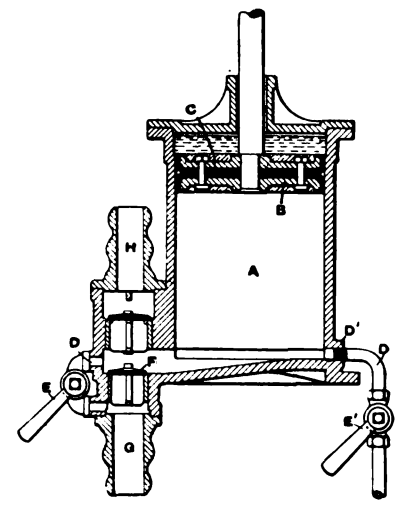
ELECTRICITY.

SECONDARY BATTERY FOR MINER'S LAMP.—*M. Bailey & J. Warner, London.*—Narrow glass or ebonite cells are placed side by side in the enclosing wooden box, and the elements are folded over the sides of the contiguous cells, and placed so that the same plate is an anode in one cell and a cathode in the other. The plates are made of lead, and are constructed in the form of a mesh of finely woven strips of metal, and with a selvage or bound edge. After the cells have been filled with sulphuric acid, they may be charged from a dynamo. The terminals are formed in the substance of the enclosing box, in order to facilitate the re-charging of the battery. The inventors claim: (1) A battery formed as described connected with a mining incandescent lamp; (2) the application of the wire mesh elements to the battery; (3) the method of suspending the elements so as to avoid all joints and connections.—No. 16669. December 3rd, 1887. 6*d*.

DYNAMO-ELECTRIC MACHINE.—*J. Y. Johnson, London. (W. C. Rechniewski, Paris.)*—This invention relates to an improved construction and combination of the cores of electromagnets and their armatures. The plates of the inducing electromagnets are stamped out from the same sheets as are employed to make the discs or rings which constitute the core of the armature. The elements of the electromagnets are arranged side by side in the same way as the discs or rings forming the armature. The plates can thus be insulated from one another, and the magnets can be combined with toothed armatures which have parts projecting radially from their periphery. The powerful field which can be obtained by the toothed armature can be produced by this invention without the disadvantageous Foucault currents which usually result from the passage of the teeth before the pole pieces. The inventor makes two claims for these improvements.—No. 15588. November 14th, 1887. 6*d*.

SAFETY DEVICE FOR ELECTRIC CIRCUITS.—*A. C. Cockburn, London.*—This invention is intended to remove the unreliability of fusible cut-outs and safety catches in electric circuits. A wire or strip of metal of one or more pieces, capable of being fused when the current passing through it is above the normal strength, is weighted at its middle, in order to assist its rupture when melted. The inventor makes three claims for the loading of the fusible safety device for the purpose described.—No. 4138. March 19th, 1887. 8*d*.



DYNAMOS.—*H. H. Leigh, London. (J. L. Clerc, Paris.)*—The armature consists of pairs of cylindrical coils, forming a set of electromagnets, and fixed radially to the axis of rotation in such a position that their poles rotate past the poles of the field magnets. The coils are wound so as to produce alternating polarities for two adjacent magnets, and are excited by a current taken from a field magnet coil by a commutator on the armature axle. The commutator consists of three copper rings embracing an insulated sleeve, and insulated from each other. The projections on these rings are irregular, and the number of them on each ring is half the number of the field magnets. Two of them have equal projections, while the projection of the third is equal to one-fifth of that of the others. The three rings are fixed relatively to each other, and in such a manner that at a given moment the current is interrupted for the purpose of avoiding short circuiting or sparking. The rings having the larger projections are connected to the armature wires, while the ring with the smaller projection is unconnected, and, if required, may be replaced by some other insulator. The coils of the armature are wound either singly or in series, their connection with the exciting coil of the field magnet being effected by a pair of brushes which are mounted in such a way that as one is leaving one projection on the commutator to contact with the next, the other of them is upon the unconnected projection. The coils of the field magnets are made by winding copper wire upon a core of iron wire, and the core is made by winding an insulated iron wire upon a U shaped mandrel. The mandrel is then inverted upon a wood sole plate, by means of which the coils are fixed to the side plates of the machine; the ends of the mandrel constitute the pole pieces. The coils of the field magnets may be coupled either singly or in series. The inventor makes three claims for the method of making the field magnets and the commutator, as described.—No. 563. January 13th, 1887. 8*d*.

CHEMISTRY.

ALUMINIUM ALLOYS.—*A. Mann, Twickenham.*—The inventor mixes sulphate of alumina with the chloride of some metal, such as sodium, which will undergo decomposition when exposed to heat. This mixture is subjected to heat in a retort, and the resulting mixture of chloride of aluminium and sulphate of soda is treated with hydrate of lime, and the whole mass laid aside for some weeks to mature. A mixture of aluminium sulphate and some de-oxidising agent, such as charcoal, is then added to the other mass, together with some scraps of metals with which the alloy is to be made. The exposure of this mixture to the heat of a furnace produces the desired alloy. In practice the alloy of aluminium and copper obtained by this process is too hard and brittle for working, and in order to overcome this defect a small proportion of brass or zinc is added, with the result of increasing the malleability and ductility of the metal. The inventor makes four claims.—No. 9313. June 30th, 1887. 6*d*.

DYEING WITH ANILINE BLACK.—*J. Grunhut, South Shields.*—This invention consists of a new process of dyeing fibrous materials in the raw or woven states. The materials are first subjected to the action of a mordant which is composed of a solution of soda or carbonate of soda and an azo dye. After being boiled in this mordanting solution the materials are washed, and are subsequently oxidised, and dyed in aniline black by being placed in a vessel containing a mixture of aniline oil, hydrochloric acid, and bichromate of potash. Instead of the latter dyeing mixture, suitable proportions of aniline oil, aniline salt, hydrochloric acid, and bichromate of potash may be employed. Such products of aniline as naphthylamine, rosaniline, or xylidine may also be used as the base of the oxidising and dyeing solutions. The inventor makes one claim for the above improved process in dyeing.—No. 15432. November 11th, 1887. 6*d*.

FILTERING METALLIC SALTS.—*C. T. J. Vautin, London.*—This invention consists of improved apparatus for separating the metallic salts from powdered ore, or from other granular material. The filtering process is hastened by means of a suction pump, and the filter is kept free and clean by the reflux of a portion of the pump charge through the filtering medium. A section of one form of apparatus designed with this object is shown in the accompanying figure. The pump barrel A is formed of some material which will not be attacked by the salts. When solutions of chlorides and bromides are treated, the most convenient material is an alloy of lead and antimony, and the piston B is packed with the cup leathers C for the same reason. At the left hand side of the figure a branch communication D is made between the upper side of the suction valve F and the lower suction pipe, and is fitted with a regulating cock E. If this branch is left partially open, the piston, on its lower suction stroke, draws the liquid through the suction valve F, and also through D, which is of small relative area to the suction and delivery pipes. Upon the

return stroke of B, a portion of the charge will return by the passage D, through the suction pipe G, back to the filtering medium, while the remainder of the charge passes through the delivery pipe H in the usual way. This effect may be produced by placing D at D¹, that is, in communication with the bottom of the barrel A; this pipe should also be fitted with a hand cock E¹. The inventor also specifies two other modifications for attaining the desired object, and makes four claims for the design of the vessel and for the three forms of the apparatus described.—No. 15575. November 14th, 1887. 8*d*.

MISCELLANEOUS.

PURIFYING CRUDE SPIRIT.—*J. A. F. Bany & M. C. A. Ruffin, Paris.*—This invention is for the purpose of introducing improvements in the process described in the specifications of patents No. 10870 of 1884, and 783 of 1886. The spirit to be treated is first rendered alkaline in order to remove the aldehyde. It is then charged into a vessel, into which pure petroleum oil is pumped through a perforated pipe near the bottom. The oil rises in streams through the spirit, and flows over the top into the first of a series of vessels to be regenerated. This series comprises a filter for entrapping solid matter, a washer for retaining any spirit which has been carried away, several vessels where it is subjected to the action of sulphuric acid, and finally a vessel containing alkali for the neutralising of any acid contained in the oil. Each of these vessels is arranged with a perforated floor, on which are placed fragments of substances not attacked by acid. The oil enters under the perforated floor, rises in sub-divided streams, and flows over the top of the vessel into the next. The regenerated oil passes from the last of the vessels into a pump which forces it back into the vessel containing the spirit. The time required to effect the complete purification of the spirit is between twenty and thirty hours. By the use of petroleum of considerable specific gravity, not flashing under 140°C., the risk of fire is avoided, and as this oil is not volatile all the vessels may be open. The inventor makes two claims for the method and apparatus respectively.—No. 5337. April 12th, 1887. 8*d*.

PITCH CHAINS AND CHAIN WHEELS.—*A. Spencer, London.*—Each link of these pitch chains is composed of two longitudinal members, of the shape of flattened rings or loops, connected by a transverse piece at one end, from which projects a neck provided with trunnions of a T form. The general arrangement of the parts is such that the trunnions of one link can be inserted within the loops of the other. According to a modification, the loops and links are made on the same principle, but of rectangular shape. The object of these two arrangements is to obtain a chain which is not extensible when subjected to long continued strains. There is one claim.—No. 4119. March 18th, 1887. 8*d*.

CENTRIFUGAL SEPARATOR.—*J. Gray, Stranraer.*—The apparatus constituting this invention consists of a receiver which is secured to and carried on a vertical spindle. The bottom of this receiver or separator is truncated, and at the top of the truncated part a vessel is secured concentrically with the spindle. The milk is conducted to this vessel by a supply pipe, and from the bottom of this vessel the milk flows out through apertures in tubes which extend from the bottom of the vessel to the lower part of the separator. The upper edge of the receiver has a rim upon it which projects concentrically inwards and outwards, and from the inwardly projecting part there rises a concentric bevelled or inclined collar. In the rim, between its inner edge and the side of the collar, are a series of holes through which, as the receiver is rotated, the cream rises into the collar and over its upper edge. Thence the cream passes into a dish which has a downwardly inclined bottom secured to an outer casing. At one part the rim round the receiver is duplicated, that is, it is composed of two plates with a space between them; and an opening is formed between the outer edge of the under plate and the vertical side of the receiver, through which the skimmed milk rises into the space between the two plates. From this space the milk flows through an opening made in the rim at the outer side of the collar, and it thence flows into a vessel secured to the outer casing. Into the annular space between the outer casing and the inner rotating receiver, a pipe and jets are introduced, and through the jets a stream of water issues and plays on the receiver. The effect of this action is the better separation of the liquid. The inventor makes three claims.—No. 2747. February 22nd, 1887. 8*d*.

TREATMENT OF FIBROUS PLANTS.—*J. Longmore & W. L Watson, London.*—This invention is designed for the extraction of the fibre from exogenous plants, such as Boehmeria nivea. The stems of the plant are made into bundles and boiled for a few minutes in an open vessel containing a solution of caustic soda. This process dissolves the gum contained in the plant, and the outside black bark can then be removed by hand. The fibres are left clear by the removal of the tissue, and are ready for use after having been washed and dried. Instead of removing the bark in the foregoing manner, another method may be employed. The dried stems are dipped in cold concentrated sulphuric acid for a short time; this treatment decomposes the bark, but allows the gum to remain. The stems are then placed in cold water, which causes the bark to swell up and leave the stem. In some manufactures the gum is required in the fibres, and in these cases the latter process is carried out. Both of these methods of treatment have been found by the inventors to be comparatively harmless to the fibre. Three claims are made.—No. 3715. March 11th, 1887. 6*d*.

GRINDING AND POLISHING MACHINES.—*W. Barraclough, Stanningley, Yorkshire.*—The object of this invention is to provide means of confining the resulting dust and grit, and also to render the spindles more adjustable than those in ordinary

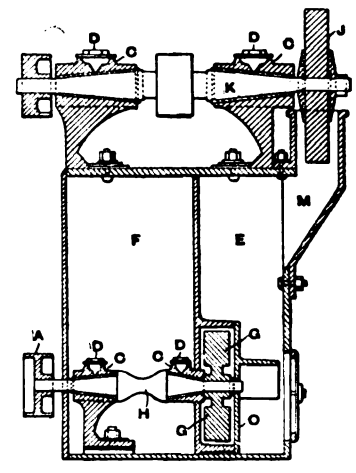


FIG. 1.

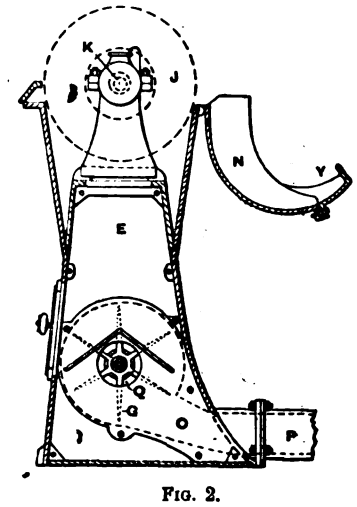
machines. Figures 1 and 2 represent respectively an end elevation and a vertical section of the improved apparatus. The pedestal is divided into two compartments E and F, and the spindle K rests in conical bearings on the top of the pedestal. The grinding wheel J is mounted on K, and is partly enclosed in the hopper M, and a hinged cover N fits over the wheel, in



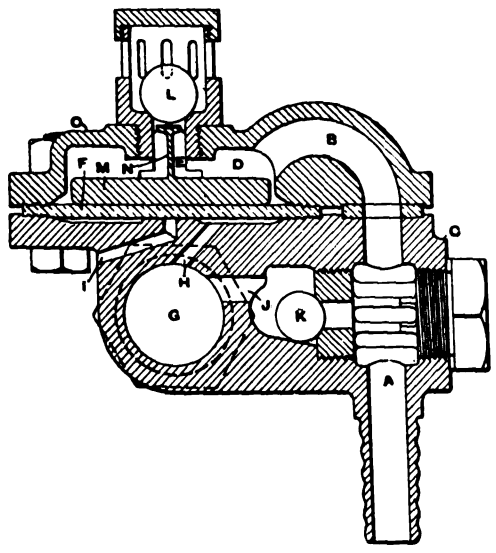


FIG. 2.

order to keep the dust and powder from flying about. The cover has an adjustable end Y, so that it may be made to suit the different sized grinding wheels. The lower part of the hopper opens into the chamber E, in which the fan G revolves; a chamber O surrounds the fan, except where the hole Q is left. The light particles of dust are drawn from the chamber E by the suction arising from the fan, and the blast from the fan expels them through the exhaust pipe P. The fan may be driven by a belt which passes round the pulley A and the corresponding one on the shaft K, or by a belt passing round H. The adjustment of the spindle bearings in case of wear is provided for by the conical shaped bearings of H K; and the oil cups C are provided with covers D in order to keep out the dust. The inventor claims the combination of parts for exhausting the dust and for adjusting the spindles.—No. 4971. April 4th. 1887. 8*d*.

Digitized by Google

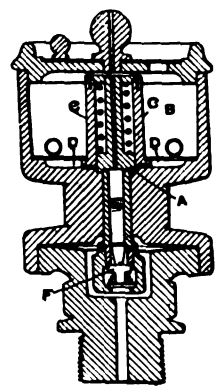
Lubricating Spindles.—*J. Gamble, Belfast.*—This arrangement is for retaining the lubricant on the vertical spindles, which have sliding bearings, and is specially designed for the roving, spinning, and twisting frames used in the preparation of flax and jute. This invention provides a means for preventing the waste of oil which escapes out of the collar bearing. A cup is attached to the bottom of the collar of the spindle, and annular layers of flannel, sponge, or other absorbent material are placed within it, so as to fit the spindle. On the bottom of the collar are projections which prevent the absorbing material from rotating with the spindle, and the spaces within the projections form openings for admitting the surplus lubricant into the annular space between the cup and the spindle. The absorbent material prevents the lubricant running down the spindle; and as the collar and its cup descend, the spindle is cleared and exposed afresh to the lubricant. There is one claim for this method of retaining the oil.—No. 4561. March 28th, 1887. 6*d.*

Valve for Vacuum Brakes.—*F. A. Brüggemann, Altona, Hamburg.*—This apparatus is shown in vertical section in the accompanying figure. The casing C is fitted to the train pipe G and contains two valves K and L, the former closing the communication between the train pipe and the passage A, which leads to the brake cylinder, and the latter closing the communication between the valve box open to the atmosphere and the passage B. A flexible diaphragm F divides the space D into two parts; and the tube H leads to the train pipe, and the weight M rests on the upper side of the diaphragm and is connected to the stem N which projects into the passage E. The

check valve K allows air to pass from the brake cylinder into the train pipe and prevents its return, and the valve L closes communication between the outer air and the brake cylinder. When the train pipe is exhausted the space under the diaphragm F is also exhausted through H. The diaphragm is thus pressed down and the pipe I is closed. If air be now admitted into the train pipe, F will be subjected to pressure on its under side through H, and will be therefore raised. Atmospheric air will thus be admitted through I into the bottom of the chamber D, and will pass directly into the train pipe through H. The stem N will raise L from its seat, and thus admit full atmospheric pressure through the top of the chamber D and the passages A B into the brake cylinder. The diaphragm F and valve L will remain in their raised position until the air pressure on both sides of the diaphragm is equalised, whereupon the diaphragm will be pressed down by its own weight, and will close the air passage H and the valve L. The inventor makes two claims for this combination of valves K L, passages I H, and diaphragm F with the train pipe, for the purpose described.—No. 16246. November 25th, 1887. 6*d.*

Lithographing Process.—*C. Salcher & H. Schwertschlag, Harland, Austria.*—The object of this invention is to provide a metal plate which will efficiently replace the costly lithographic stone. A zinc plate is generally used. The plate is first etched with an aqueous solution of nitric acid, in order to roughen its surface slightly; it is then coated with slaked lime and allowed to dry. Owing to the action of the air the lime is partially changed into carbonate, which firmly adheres to the surface when it is brushed. This process may be repeated several times, in order to insure a perfect coat of carbonate of lime. Before the transference of the design to the plate the latter is washed with a strong solution of alum, whereby a small quantity of alumina is added to the coating, so as to render the surface more capable of absorbing fatty substances. The plate is then rinsed with water and is ready for the transfer, which is accomplished in the usual manner. The inventors make one claim for the process, as described.—No. 17162. December 13th, 1887. 4*d.*

Treating Leather.—*H. Golding, London.*—In order to render leather water proof, and at the same time to increase its durability and improve its appearance, the inventor applies a solution of resinous gums, linseed oil, and turpentine. The leather is to be impregnated by this mixture, and not merely coated, and the process is to be conducted while the solution and the leather are warm. The inventor makes one claim.—No. 3860. March 14th, 1887. 6*d.*



Consumption of Smoke.—*A. M. Clark, London.* (*P. Oriolle, Nantes.*)—This invention applies more particularly to consumption of smoke given off by the engines which drive a torpedo boat, but it is also applicable to any boiler which has a forced draught. The chimney stack is not very high, and is surrounded by an iron vessel of rather greater height, and of five times its sectional area. The gaseous products of combustion, together with the unconsumed carbon, pass up the funnel and down this exterior vessel, and their velocity of descent is retarded in consequence of the greater area of the surrounding casing. In the top of the casing is a perforated iron plate, through which water is pumped. A shower of very finely divided spray enters the smoke space through the perforations, and condenses the gases and carries the soot along with it to the bottom of the casing. The resulting solution passes out into the sea. The inventor makes two claims for this construction of parts for the purpose described.—No. 4749. March 30th, 1887. 8*d.*

Ventilation of Mines.—*J. Taylor, Sunderland, and W. Whitfield, Gateshead.*—The inventors lay branch pipes all through the mine which are connected to a main pipe descending the shaft. Air is pumped down this pipe by means of a fan, and is conducted along the branch pipes to the face of the workings. The air returning along the headings and shafts carries along with it all the gases which it is desirable to clear away. The remote parts of the mine can be reached by this system, as the draught can circulate without there being two openings to a heading. The inventors make one claim for the above method.—No. 17069. December 12th, 1887. 4*d.*

Straightening Steel Wire.—*J. Thornton, Cleckheaton, and W. Walker, Scholes, Yorkshire.*—A metal roller is mounted on bearings, and is either conical or cylindrical in shape. Along its curved surface are spiral grooves, and runners are placed in slots at various points in the lengths of the grooves. The wire to be straightened is led through the tubular bearing of the roller and passes along the spiral grooves; and on arrival at the other end of the roller it is led off through the corresponding hollow bearing. The roller may either be stationary or revolve, and the wire is drawn off the cylinder by suitable drawing rollers. By this process it is found that the wire is effectually straightened and that its properties are not damaged by the action; thus no tempering is required. The inventors make two claims for this improved method.—No. 2484. February 17th, 1887. 8*d.*

GERMAN PATENT ABSTRACTS.

Lubricators.—*B. Heinrich & A. Schoschnig, Posen.*—The lubrication is effected in two periods. In the first period the perforated piston A closes the two oil passages D, and also the cylinder C, thereby preventing the oil from escaping out of B. Air is admitted into E by the perforation of A. In the second

period the valve casing, and with it the oil reservoir E, is lifted by the pressure of the steam, thereby forcing the piston A upwards, opening the oil passages D, and allowing the oil to pass through D into E. As soon as the steam is cut off and a partial vacuum formed, the valve F is opened, and the oil sucked into the cylinder.—No. 41769. February 19th, 1887.

UNITED STATES PATENT ABSTRACTS.

Governor for Steam Engines.—*J. A. Horton, Reading, Massachusetts.*—The four arms supporting the governor balls are arranged as usual in the form of a parallelogram; but the two lower arms support the apparatus in the fixed bearings. The spindle slides vertically in a bearing at the upper angle, where the two higher rods are jointed, and the upward and downward movement of this joint, consequent on the fall or rise of the weights, transmits motion to the valve by means of a rack on the vertical spindle and a pinion on the valve shaft. The inventor makes one claim for this arrangement of the governor.—No. 377028, dated 31st January, 1888.

Journal Bearing.—*M. Randolph, New York.*—The inventor employs a journal and bearing composed of vulcanised fibre, and in order to reduce the friction as much as possible, circular transverse grooves are made in the friction surface. A lubricating material, composed of plumbago and some adhesive cement, is placed in these grooves. The inventor makes one claim for this combination of the journal with the plumbago placed in the grooves.—No. 377049, dated 31st January, 1888.

Compound for Coating Iron.—*J. F. Martin, Chicago.*—In order to protect the surface of wood, iron, and canvas, a compound is made by mixing common glue, paris white, sulphur, and shellac together with any colouring matter which it is desired to cover the material with. The application of colour in this way preserves the surface of the material, and also makes the coat of colour last longer. The inventor makes nine claims for this compound coating.—No. 377081, dated 31st January, 1888.

Traction Cable.—*P. J. Fransze, Chicago.*—A strip of metal with bevelled edges is wound in a coil so as to form a continuous spiral covering for the hemp, or other rope, used in drawing railway cars. This method of construction enables the rope to be easily bent, without any disadvantage to its own construction; and the metallic covering serves to strengthen the rope, and to protect the hempen core. Two claims are made.—No. 377023, dated 31st January, 1888.

Polishing Powder.—*V. Seib, Albany, New York.*—The inventor proposes to manufacture a cleaning and polishing powder from coal ashes. The ashes are re-heated and re-burned, and afterwards boiled in water. On the conclusion of this process the ashes are allowed to settle, and when dried are ready to be used for the purpose stated.—No. 376211, dated 10th January, 1888.

Adding Machine.—*W. F. Gatewood, Harvard, Nebraska.*—In the accompanying diagrams Fig. 1 represents a central horizontal section, and Fig. 2 a vertical section of the improved machine. The apparatus is contained in a box A. The finger pieces C^1 and levers C are connected with the rocking shaft E. The index wheel F is mounted on the horizontal shaft F^2, which is supported

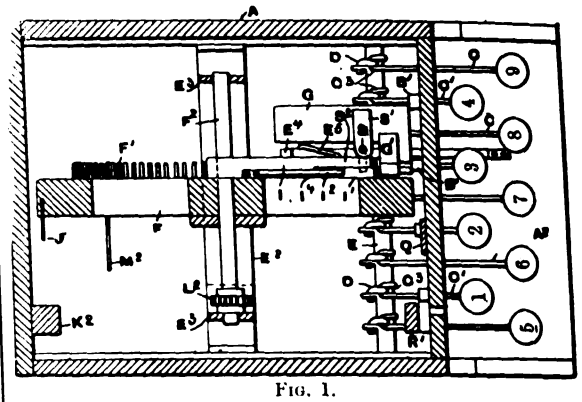


Fig. 1.

on the standards E^3; and round the rim of the wheel are 99 projections F^1. The lever I is pivoted loosely on the shaft F^2, and at its other end is a movable pawl I^1; and the rod E^5 connects I with the lever E^4 and rock shaft E. When one of the number plates C^1 is depressed one of the levers E^4 is raised against the action of the spring E^1, and the arm I is consequently raised. The pawl I^1 travels upwards past as many of the projections F^1 as correspond to the number on the depressed plate C^1, and when the pressure on C^1 is released the pawl I carries the wheel F round with it. The gravity tooth H prevents any

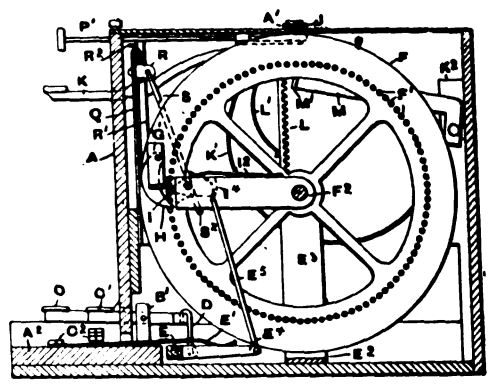

Fig. 2.

accidental backward motion of F. The consecutive numbers from 1 to 99 are placed in series round the periphery of F, and an opening A^1 in the top of the case enables the operator to observe the sum total. A spur and pinion gear registers the hundreds and thousands, which are read off on a dial placed beside the opening A^1. The mechanism above described is for the purpose of adding; there is also some parts of the machine which are used for returning the index wheel to its original position, where it registers zero at the opening A^1 in order to commence a fresh series of additions. The lever K is pivoted to the support K^2, and is held in an elevated position as in the figure by the spring K^1. A rack L is pivoted to the middle part of the lever K, and is held vertically by the spring L^1. In order to bring the wheel back to zero the lever K is depressed so as to bring the rack L into gear with the pinion L^2. The same movement of K lifts the arm 1 and pawl I^1, and the repeated depression of K rotates the wheel F until the stop M^2 on the wheel comes in contact with the projection M, which places the zero mark opposite the hole A^1. The lever P^1 serves to restore the pointer J to zero. The inventor makes eleven claims for this apparatus.—No. 370777, dated 4th October, 1887.

Uniting Pipe Sections.—*A. L. Murphy, Philadelphia.*—The ends of the metal pipes which are to be joined together are made of a slightly greater diameter for a short distance, and a small length of pipe is introduced into the two contiguous enlarged ends. The whole is then placed together and welded into one piece. The inventor makes four claims for this process.—No. 376750, dated 24th January, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

TRIPLE EXPANSION LAUNCH ENGINES.

CONSTRUCTED BY MESSRS. WILSON & CO., VAUXHALL IRON WORKS, LONDON.

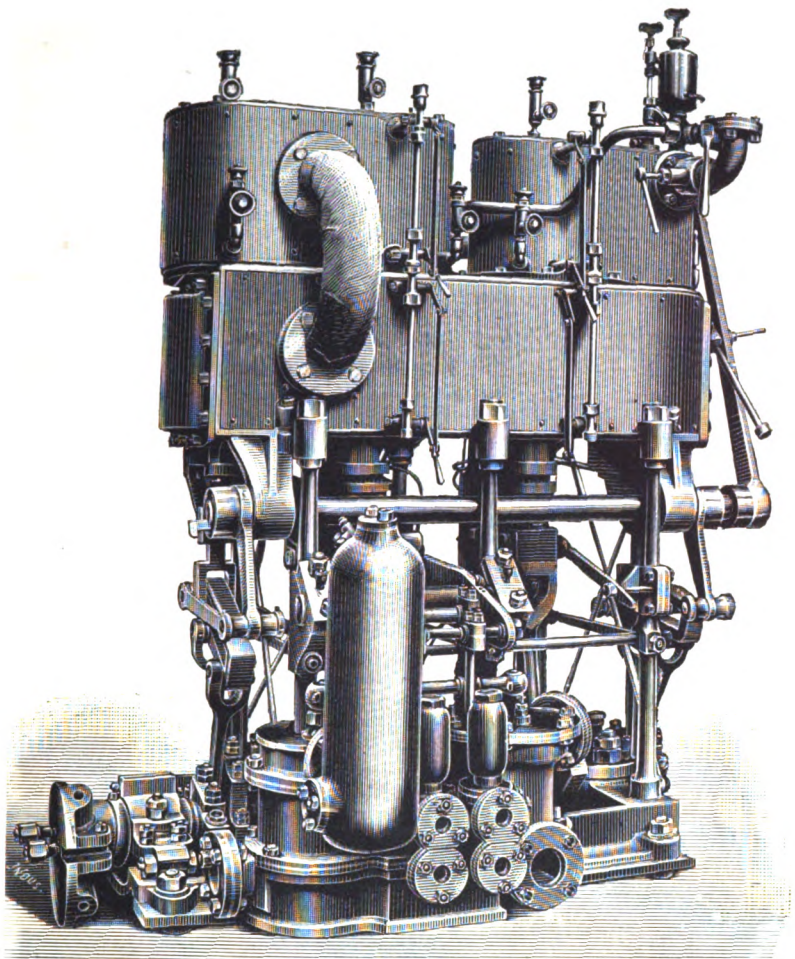

FIG. 1.

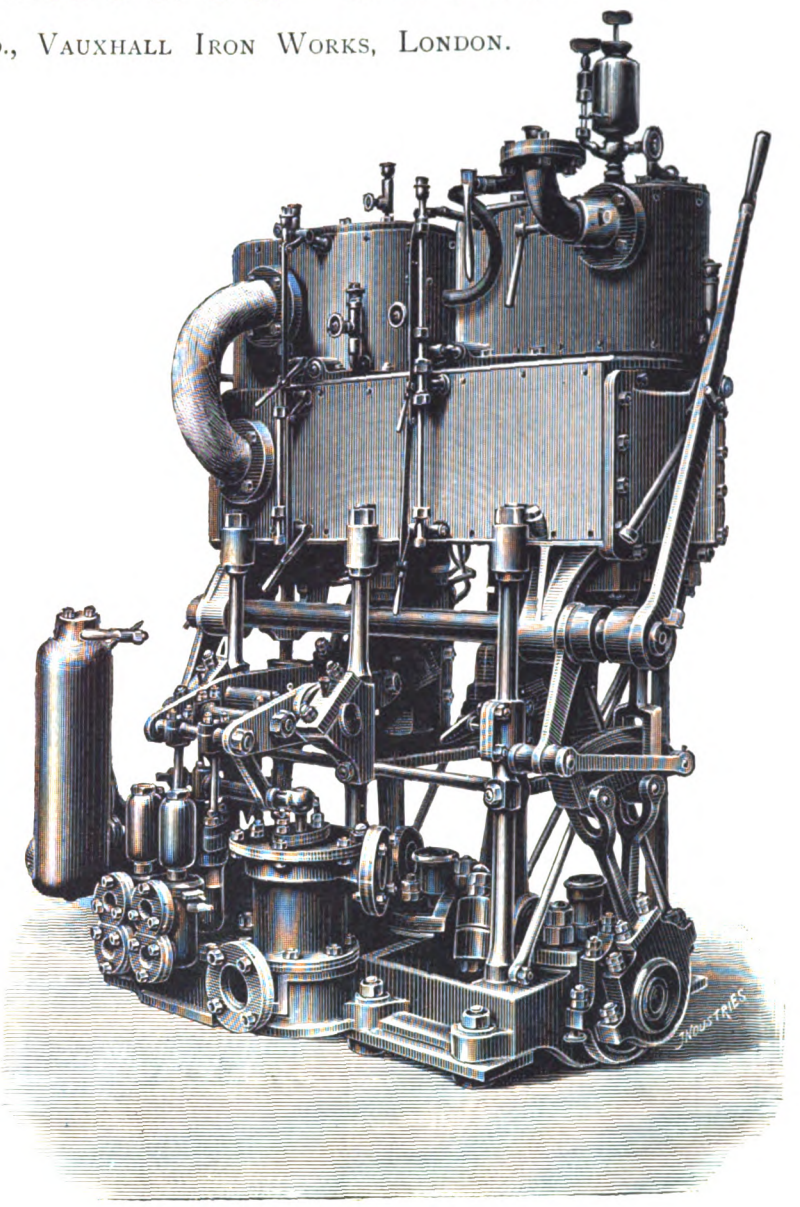

FIG. 2.

A JAPANESE ART COMMISSION.

FOR the past dozen years or so Japanese art has influenced almost all our domestic ornamentation and many of our art industries, and it may interest our readers to hear some Japanese opinions about Western art, as given by a member of a commission of artists and students which was dispatched by the Japanese Government to report on the subject. The official report has not yet been issued; but one of the members of the Commission on his return to Tokio delivered a lecture to the leading native artists of the Japanese capital, and from it we can gather some of the opinions which are likely to be found in the report.

We are pleased to learn that the lecturer believed that it was a duty Japan owed to herself to develop her own methods and ideals, for there has been too great a tendency during recent years for all the truly valuable features in Japanese art to be vulgarised to suit the demands of ignorant foreign visitors. The lecturer before his tour defended Japanese art on national grounds, but his observations during his travels confirmed him in his opinions. While admitting that European art was very fine in itself, he was strongly of opinion that the tendency to copy it in Japan would crush out the peculiar Japanese spirit and individuality; and after a lengthened study of Western fine arts, the social conditions which led to their characteristics, the state of art education, and the relations of modern art to industry, supplemented by conversations with leading art teachers, critics, painters, sculptors, architects, and manufacturers, the members of the Commission expressed the following rather startling opinion: "The new evidence which we have found conclusively proves that good Eastern art is better than the present style of Western, not only for Japan, but also for the whole world; that if Japan will improve her own art from within, it will become not merely a national movement, but one which will spread over America and Europe also. In short, Japanese art, with all its faults, is the only living art in the world to-day; and if she be true to her own best inspiration, in comparatively few years Japan will become the acknowledged centre and leader of the fine arts in all civilised countries." We may discount the rather lofty language used here, and which was recently made the subject of a clever cartoon in *Punch*; but anyone who knows anything about Japan will know that there is a great amount of truth in it. It is no exaggeration to say that the Japanese are the most artistic nation on the face of the globe, and if they cultivated their own style of art productions, and maintained a high artistic standard, they would have little difficulty in practically keeping a monopoly of their own specialties. The lecturer dwelt on the advantage to Japan, on the economic side of the art problem. He stated that in his opinion there is almost no such thing to-day as good European design; that the capacity for designing died out several centuries ago, and that the divorce between "painting" and the "decorative art" wrought by the sixteenth century paralyses the power of both. No such divorce has ever taken place in Japan, and because "she can design to-day, she can become, if she will develop her own powers, the great manufacturer of fine art products for the world. For Japanese, then, to introduce European methods of art education, would be to kill out their own power of design, and destroy their own economic future. But if Japan develops her own methods, and follows her own ideals, Europe and America will be forced to come to learn of and buy from her."

The lecturer entered into an interesting comparison of Japanese and Western methods; but into this we cannot enter, our chief object being to direct attention to the industrial aspect of the question, and to show our art manufacturers that if the spirit indicated by the Commissioners develops in Japan, they will have in that country one of their most powerful competitors.

TRIPLE EXPANSION LAUNCH ENGINES.

THE accompanying illustrations show a set of triple expansion surface condensing engines for a 50ft. steam launch, built for the use of the Admiralty officers at the Keyham and Devonport dockyards. The engines have been supplied by Messrs. Alex. Wilson & Co., Vauxhall Iron Works, London. The two perspective views (Figs. 1 and 2) are from photographs supplied by the makers, whilst the sectional elevation has been reproduced from the Proceedings of the Institution of Naval Architects. There are four cylinders—two low pressure, one high pressure, and one intermediate cylinder, the last two being placed directly over the low pressure cylinders. These are both 12in. diam., the intermediate cylinder is 10in. diam., and the high pressure cylinder 6in. diam. The stroke is 8in. The piston and valve rods pass through internal metallic glands. There are only two cranks, and this arrangement was adopted to secure economy of room, the length available in the launch not permitting the use of a three-crank engine. Piston valves are used for the high and intermediate cylinders, and ordinary slide valves for the low pressure, as shown in Fig. 3. There is no steam reservoir between the cylinders beyond the ordinary passages and connections. The pumps are worked from the piston rod cross heads. There are two feed pumps, each capable of supplying the requisite quantity of water; the air pump is 7½in. diam., and the circulating pump is 5⅜in. diam.; the crank shaft is 3in. diam., of wrought steel, and the piston and connecting rods are also of steel.

The surface condenser supplied with the engines has 225 solid drawn tubes ⅝in. in diameter, and presents a total cooling surface of 120 sq. ft. The boiler supplied for the engines is of the ordinary cylindrical return tube type, with one circular furnace. It is worked at 140lb. pressure, and is constructed entirely of Siemens-Martin

TRIPLE EXPANSION LAUNCH ENGINES.

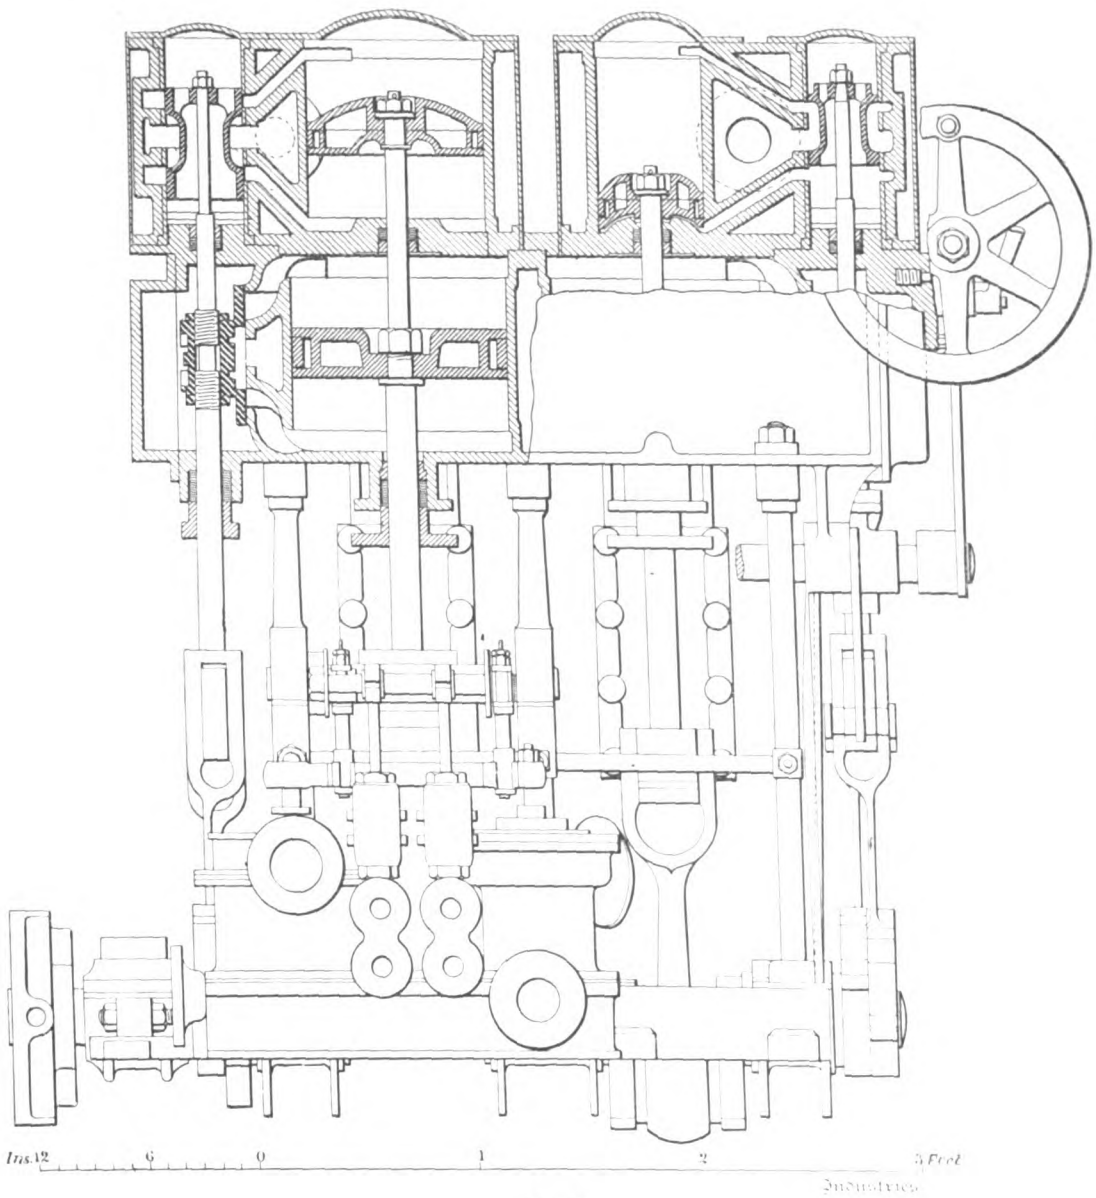

FIG. 3.

steel, the transverse seams are double riveted, and the longitudinal seams treble riveted. The shell plates are $\frac{9}{16}$in., the end plates $\frac{5}{8}$in., and the furnaces $\frac{7}{16}$in. The grate surface is 10 sq. ft., and the tube surface 180ft. At a trial trip of three hours' duration, the consumption of coal was found to be 2·54lb. per i.h.p. per hour. The mean pressure in the cylinders was 51·1lb. for the high, 36·9lb. for the intermediate, and 10·5lb for the low pressure cylinders, the boiler pressure being 139·1lb. per square inch. The total i.h.p. was 70·8, giving 7·08 i.h.p. per square foot of grate surface, and about 1 i.h.p. for every $2\frac{1}{2}$ sq. ft. of tube surface in the boiler. The speed of the launch was 9·26 knots per hour, the crank shaft and screw making 283·4 revolutions per minute. The screw is 3ft. 6in. diam., 4ft. $1\frac{3}{8}$in. pitch, and made of gun metal. The engines are supported on cast iron bed plates by a wrought iron frame work, with diagonal stays. The valves are worked by double eccentrics and link motion at each end of the crank shaft. The engines have been designed to suit a launch already built, and as these small craft are frequently employed on detached duty, the quantity of coal to be carried is of importance, and it was for this reason that triple expansion was adopted. The result of the trial shows that the economy resulting from triple expansion is not confined to large engines; and the fact that 70 h.p. has, at a moderate speed, been obtained from steam passed through a 6in. high pressure cylinder, is significant of the degree of perfection which the triple expansion principle has now attained.

ITALIAN RAILWAYS.

MR. J. G. KENNEDY, Her Majesty's chargé d'affaires at Rome, is informed that the Italian Minister of Public Works has undertaken to formulate proposals for the future construction of railways in Italy. Three plans are to be adopted, the first being the construction by the State at an expense of £18,960,000, spread over four years, of lines already commenced, and of other lines which could not conveniently be conceded to private enterprise. The second is for the concession of construction and working of a certain group of railways to the Southern Railway Company, which is to construct and work the system at yearly payments of £822 per kilometre, to be paid from the date of the completion of the works up to the year 1996. By the third plan concessions will be given to the highest bidder for the Rome-Naples, Eboli-Reggio, and Messina-Cerda lines. The object of the scheme, which has to be passed by Parliament, is to promote railway construction without imposing immediate heavy expenses on the Government.

THE COTTON INDUSTRY AND TECHNICAL EDUCATION.

THE cotton trade of this country, holding, as it does, an important position amongst our manufacturing industries, suffers perhaps more from the keenness of competition than that of flax, woollen, or silk. English and Scotch manufacturers are not only handicapped in the race for existence by the immense production of home concerns, but are now feeling the serious effects of being undersold in foreign as well as in their own markets at home by the cheaper, although less substantial, products of foreign manufacture. With the low wages paid, and long hours worked by foreign artisans, the position of our producers is no doubt a precarious one, and as each year competition from abroad must necessarily increase by the establishment of manufactures where they do not now exist, and by their extension where they have already found a seat, we can only hope to retain our supremacy for some years longer by the production of a better article in appearance and quality, and in the working of our machinery with more economy and advantage. Technical education has of late contributed, to some extent, towards improving the capabilities of many of the young men connected with our manufactures; but considering the number employed in mills and factories, the percentage of technical students is yet extremely small. Every year, however, will, we hope, see some development of this system of instruction, for technical schools are now recognised as not only useful but essential institutions.

Some years ago it was the general opinion among manufacturers that their employés should only be allowed to obtain a knowledge of some one particular department, any attempt to gain an insight into the others being strictly forbidden; but this narrow minded system is now happily dying out, and many manufacturers are now found among the chief promoters of industrial education. Without instruction of this kind, we may easily realise that the heads of the various departments in our mills and factories must, to a great extent, be merely experimentalists. Suppose, for instance, we take the case of a young man brought up in a cotton mill through the successive stages of lap carrier, stripper, grinder, and under carder; and that after mastering the various details and work attached to these positions, he finally obtains an appointment as head of a department. He may attend well to his duties, and devote his time and energy to producing increased work, either by alteration in the existing arrangement of weights, speeds, or system; but having only his own practical experience to guide him, he is forced to try one plan after another to achieve success, whereas, had he been properly taught, he would, in addition to his own knowledge, have possessed the combined experience of others who had passed through these various experimental stages before him.

From a proper course of technical education numerous other advantages are to be derived. For example: a knowledge of the mechanical structure and other properties of the material used, and of the various uses to which it is to be applied, also the best methods to adopt in order to work it with full advantage at any particular process, and so that it may be best adapted for those which succeed it. Not long ago, the majority of those who held responsible positions in cotton mills were entirely unacquainted with the different divisions of the cotton plant product, and the characteristics which distinguish the various fibres. To be able to discriminate between long and short, dirty and clean, and strong and weak cotton, was—and is in some cases even yet—looked upon as all that is necessary to constitute an accomplished buyer, and one in whom the greatest confidence might be placed. At the present time even, when education in almost every other department of industry is so far advanced, we may safely assert that not one per cent. of the operatives employed in cotton mills know anything whatever of the cotton fibre beyond its delicate, silky, outward appearance. Twenty years ago, education on such a subject was, even on the part of the managers and overlookers of spinning factories, not necessary or essential, and in fact practical knowledge of the business could have been dispensed with on the part of the manager, if he possessed tact, commercial ability, and sufficient general experience of the work in the various departments to enable him to pass through the ordeal of an ordinary conversation. Little else at that time was required, as competition like that felt at the present was almost unknown, and therefore quality, quantity, and economy in production beyond a very moderate standard was never expected. The demand from consumers was always in excess of the supply of both cotton yarns and cloth; consequently, instead of having accumulated stocks, companies could then dispose readily of their produce at rates which left ample margin for the payment of large profits to the shareholders. Now, however, the position of affairs is altered; and managers and overlookers should therefore be men of recognised ability, and be practically acquainted with every detail of the processes employed in converting the raw cotton into finished yarn, and finished yarn into cloth.

In short, if we are to retain our manufacturing supremacy, it must be by rendering our spindles and looms capable of rapidly producing cheaper and better articles than our foreign competitors. This object we can only hope to accomplish by business energy, and by imparting to our workpeople a more intimate knowledge of the raw material, and the distinctive features of each variety. In this way any part of a process which might be liable to injure its natural qualities could be avoided, and probably something else substituted with equal, if not better, effect. The treatment of all classes of textile fibres in manufacture may be compared to that pertaining to the human body; for, in the latter case, unless the physician understands the nature and root of any disorder, it is not to be expected that he will be able to successfully prescribe. Similarly, therefore, in the working of cotton, it is obvious that unless those who may have the arrangement and working of the machinery under their charge thoroughly understand the characteristics and structure of the various fibres, they cannot properly determine the treatment to which it is best adapted, or which may be conducive to the protection of its qualities and properties.

Digitized by Google

The position of mill manager is, as one would naturally suppose, the chief and most important in connection with a cotton factory. On him the responsibility for the success of the concern directly rests, and, although other matters, over which he may have no control, such as dull trade and low prices, may bring about unprofitable results, incompetency on his part is usually considered the cause of them by suffering shareholders. A manager's position, especially in limited companies, is not at the present time an easy one, requiring, as it does, constant and unremitting care, study, and attention. Even under favourable circumstances he is always subject to the responsibility arising from incompetency or neglect on the part of some of his numerous employés. In some mills the manager is also yarn and cloth salesman, though the custom generally adopted is to have a special salesman for this part of the business; but here, again, he is often placed under a false responsibility, as any losses occasioned by the salesman does not appear separately on the balance sheet, but is included in the item termed "loss on the quarter's working." For everything that goes wrong in the mill, the manager is rightly held responsible; but in many cases where the working has been unprofitable, an impartial investigation might reveal the fact that he was in a great measure free from blame. The manager of a spinning mill should be a man of tact, energy, and general ability; he should possess a thorough practical knowledge of the working of all classes of cotton, the blending of different varieties together, and the details of each machine in the mill and its principle of operation—from the scutching to the warping department. He should be able to work out all calculations in connection with the entire industry, and have a good knowledge of engines, gearing, and shafting. While doing his duty to his employers, he should cultivate an agreeable feeling amongst his workpeople, and endeavour to induce and sustain a friendly rivalry between the operatives in each department. He should daily inspect the working of each machine, and personally test what percentage of waste is being made at each operation. At different periods he should have the covers of the carding engines removed, and not only examine the condition of the wire, but gauge the working parts. Where combing machines are used, he should frequently inspect the top combs and cylinders. Generally speaking he should supervise everything in connection with the mill, even to the minutest detail, and leave nothing entirely to the care and discretion of those under him.

The salaries attached to the position of manager vary in modern mills from about £180 to £800 per annum. The following are average salaries for English managers at the places named:—

	£		£	Approximate average per annum. £
Bolton	180	to	800	400
Oldham	180	to	400	280
Germany	250	to	600	450
Russia	400	to	1,500	1,000
India	400	to	1,000	600
America	400	to	1,000	600

Coming now to the weaving manager, anyone holding this position should have general qualifications similar to those already stated. Unless he is competent to produce every variety of fabric, and to judge all varieties of yarn, the advantages obtained from his services will not be of much worth. He should, in addition, be a good designer and practical weaver, and be able to superintend his workpeople with care and kindly firmness. The salaries attached to this position are in England only about one-half those already given for general manager.

The secretary of a cotton mill should of course be a man of trust and integrity. He should have a good commercial education, and although a practical knowledge of the manufacture is not essential in his case, general information on the various details of manufacture is an advantage. He should be a good book-keeper and correspondent, and energetic and methodical in all his transactions. Cotton mills have now become so much like large banking concerns, that the secretary should be a good financier in order to discharge his duties efficiently. He has the loan business and the issue of deposit books to look after; he has the interest on the loans to make up and pay by cheque or warrant; he has the share capital to attend to, and he must ascertain each quarter the liabilities and assets of the company. He has also to prepare and publish the balance sheets, and to carry out the payment of dividends, while all work common to business offices comes under his charge. It will thus be seen that the secretary's position is not a sinecure, and that neglect and carelessness in the discharge of his duties must result in great loss and confusion. The salaries attached to the secretarial office are not very large, ranging from £70 to £250 per annum, the average salary in modern mills being about £150 per annum.

Referring now to the carding master, the man holding this position should be brought up in each department, and have had experience in the working of several forms of carding engines. He should be a competent grinder, stripper, and setter, and able to undertake, if required, any alterations or repairs which may be necessary in his department. He should be a good judge of cotton, and be able to attend to the mixing, or to the setting of the rollers or machines for the working of any or every kind of cotton. He should act carefully as regards the consumption of various materials, such as belting, oil, filleting, &c.; and he should be strict in the management of the workpeople placed under him. The average wages of English carders are as follow:—

	£	s.		£	s.	Approximate average per week. £	s.
England	1	10	to	3	0	2	0
Germany	2	10	to	4	0	3	0
Russia	3	0	to	6	0	4	10
India	3	0	to	9	0	5	10
America	3	0	to	5	0	4	0

The position of combing master is generally only required in fine spinning mills, and competent applicants for vacant positions are consequently never very numerous. In the working of combing machines, more study, carefulness, and attention are required than for any other class of machines. Upon this process the quality and value of the yarns produced materially depend, so that no one should be entrusted with this responsibility except he has had a large experience in the work. The wages paid are about 5 per cent. or 10 per cent. less than to carders. During recent years, the position of the spinning master has improved considerably both in responsibility and remuneration, although the applicants for vacant appointments are more numerous than for any other department. To be a competent spinning overlooker, a man must not only be a practical spinner, and have a thorough knowledge of the various kinds of machinery in use, but he requires to be able to make any change required, either in hank or twist. He should also be a good judge of yarns, and the characteristics they should possess to adapt them to the manufacture of various fabrics, laces, or threads. The wages paid to spinning masters are about the same as paid to carders.

RAILWAY CARRIAGE AND WAGGON WORKS.

By M. Powis Bale, M.Inst.M.E., Assoc.M.Inst.C.E.

III.

(Concluded from page 185.)

Passing next to the various planing machines, No. 13 on the plan represents a combined roller feed, planing, jointing, tongueing, grooving, and moulding machine, especially adapted for planing carriage floor boards, chamfered waggon sides, soles, &c. Perhaps the most useful size for railway work is a machine to plane wood up to 16in. by 6in. Angling side cutters will be found an advantage for beading and chamfering, as well as tongueing and grooving. No. 14 is a trying-up and planing machine with travelling table, useful in planing to dimensions, and taking out of "winding" waggon and carriage soles, cross bearers, stretchers, buffer beams, and such like heavy work. It will also be found advantageous for edging to gauge, as several waggon soles, or a number of boards, can be cramped together on edge and passed beneath the cutters at one time. No. 15 is a machine specially adapted for planing carriage panels and such like work. It should be fitted with vertical side cutters, so that panels, &c., can be planed and tongued to fit into the uprights and door frames without hand finishing. For working thin and valuable woods, spiral cutters may be used, as they are less liable to split thin pieces. The machine planes up to 30in., and is driven by two belts, one at either end of the spindle. A variety of hand feed surface planing machines have been introduced recently, and one or two of these would be found extremely useful in a railway carriage works for the interior joinery, surfacing, jointing, chamfering, and mitreing. The tenoning machine (No. 16) should be specially adapted for cutting single or double tenons on the sides, bearers, and diagonals of the under frames of carriages and waggons. Owing to the weight the table should be arranged with a self acting traverse motion, and to swivel. The table should be wide enough to take four waggon sole plates at once, and double tenons can be cut on them at one passage of the table past the cutters. The table is then swivelled round, and during its passage backwards tenons are cut on the opposite ends. Tenons on the diagonal can also be readily cut by this arrangement. The middle of the three cutter heads should be made movable, and the machine can then be used for rebating the ends of the sole plates for the iron rings. An extra slide carrying a cross-cut saw is useful, so that all the pieces of timber can be brought to one exact length at the same time that the tenons are being cut. One great advantage of the swivelling table here referred to is that when once the wood is fixed all the tenons are cut without its being moved, and they are all exactly parallel to each other. The table should also be arranged to cant for cutting diagonals. For cutting tenons with shoulders of unequal length, the sliding brackets carrying the cutter block spindles should be arranged with lateral as well as vertical adjustments. This may be effected by mounting the brackets in dovetail slides, and adjusting them laterally by a hand wheel and screw. These slides should be marked so that shoulders of unequal length can be cut to any desired gauge. The spindles for cutting double tenons should also have both lateral and vertical adjustments. To cut shoulders of unequal length, cutter blocks are sometimes shifted on their spindles; but this plan is both dangerous and uncertain, and should not be used.

Another form of tenoning machine is sometimes used for railway carriage work. In this the wood to be worked is cramped on a table. The cutter blocks, of which there are three, begin cutting upwards, and stop automatically when at the top. One end of the timber being thus completed, it is pushed through the machine on to another table, and being held in a similar manner, is operated upon by the cutters moving downwards. A small tenoning machine (No. 17) is also needed for light work, such as railway carriage window frames. Tenoning machine cutters should be arranged to work diagonally to the grain of the wood, and it is found in practice that the nearer the cutters act with the fibre of the wood the smoother the work. For heavy railway work, the cutting edge of the irons should have a speed of from 3000ft. to 3500ft. per minute; but in light machines this speed may be increased to 4000ft. per minute. The illustration (Fig. 15) represents a double tenoning machine, newly designed by Messrs. Thomas Robinson & Son, Limited, Rochdale, for cutting tenons on railway carriage and waggon soles, and heavy work of that class. The timber is placed on the table, which is arranged with a self acting feed, and traversed past the circular saw, which cuts it to the required length. It then passes through the tenon cutters, which cut tenons on the one end. The table is then swivelled, and tenons on the other end of the timber are cut in a like manner. The table is also made to swivel for cutting tenons on the diagonal. The cutter spindles are mounted in sliding brackets, adjustable vertically and horizontally, and the saw can also be adjusted laterally to cut timber of different lengths. Another form of tenoning machine especially adapted for cutting single or double tenons on the ends of sole bars, and diagonals, of railway carriages and waggons is illustrated by Fig. 9. It is from the designs of Messrs. A. Ransome & Co., Chelsea, London. As will be seen from the engraving, the cutters are bolted to blocks, mounted on a vertical spindle. The timber to be tenoned is carried within cast iron brackets, bolted to the main frame of the machine on either side. The timber is held in position by screw cramps, and when once fixed does not require moving, as after one end is cut it is traversed to the opposite table till the other end is in a position to be operated on. This is a distinct advantage in heavy tenoning machines, where the labour of moving the timber is considerable; and at the same time much greater accuracy is secured. The cutters are traversed past the end of the timber by means of self acting gearing, and cut one tenon when travelling forward and the other when returning.

A very important operation in the construction of railway carriages and waggons is mortising. Some of the mortises—especially those in the under frames—are of considerable width, and difficult to make in hard wood. Two types of machines are in general use—the reciprocating and the rotary—but these two types have also been combined in one machine with success. For many years vertical reciprocating machines with a positive stroke have been chiefly used, but latterly some works have adopted a graduated stroke machine. This latter—which is of American origin—possesses some distinct advantages. It can be worked gradually into the mortise from a point above the extreme upper throw at the will of the operator, and with much less jar and vibration than the positive stroke machine. This arrangement, however, has the disadvantage of increasing the number of wearing parts in the machine. By combining a rotary or routing mortise tool with a reciprocating chisel, the former may be used for roughing out the mortise, and the latter for squaring the ends; and in establishments where head stocks and soles are recessed as well as mortised, the routing tool can be used for this purpose also. In heavy mortising machines, if the chisel is arranged to drive from the base of the machine, increased steadiness in working is secured. In mortising hard wood a clearance hole for the chisel should always be bored. The best form of chisel for general purposes is a double-lipped one, with a portion of its groove parallel, and then tapered off. With this arrangement the core of the mortise is withdrawn as the parallel lips grip, and retain the chips, which are afterwards discharged through the taper clearance. In sharpening this chisel the side lips

Digitized by Google

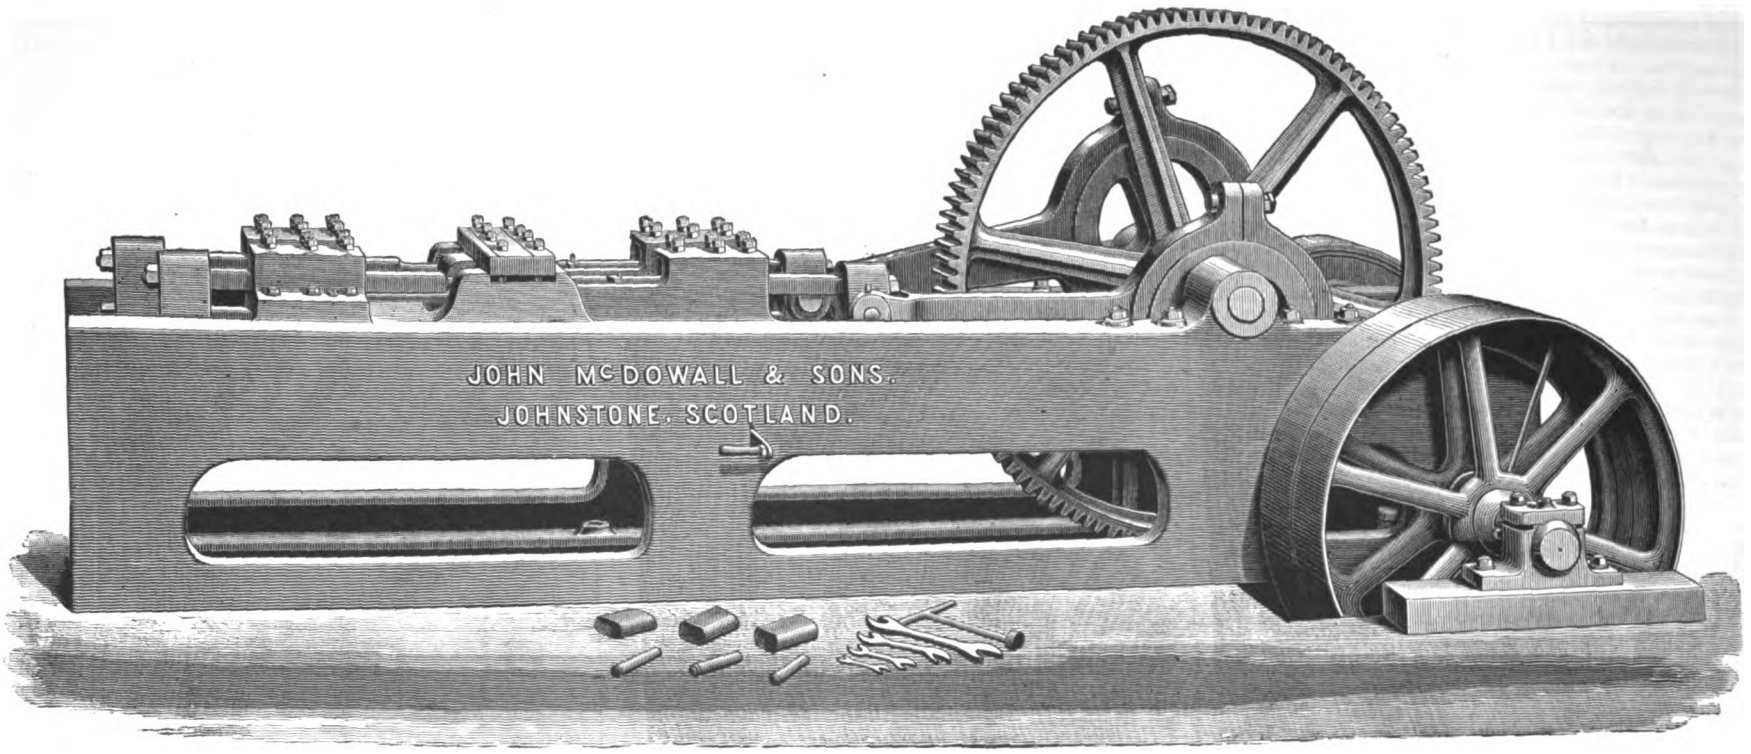

FIG. 8.

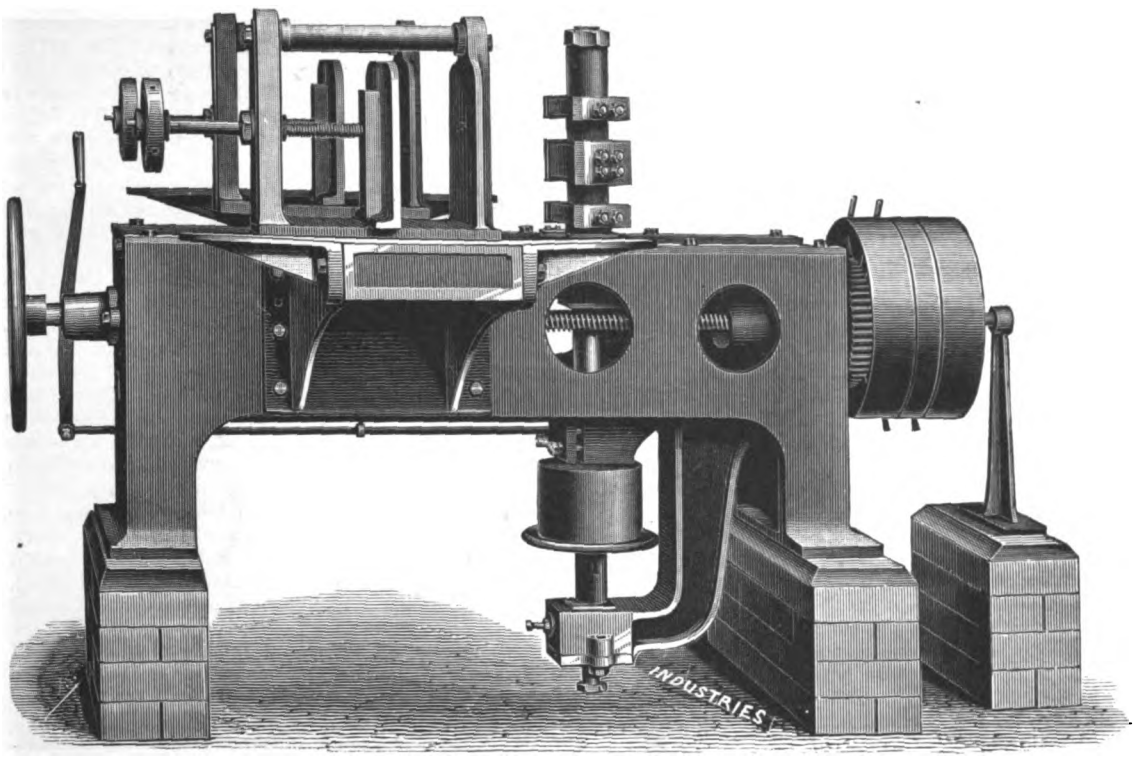

FIG. 9.

should not be touched, but kept at the same angle, and the points at the same projection. In working heavy machines making mortises up to say 3in. wide, a speed of from 175 to 275 strokes per minute will usually be found suitable. For light mortising, with a movable table, a speed of from 275 to 400 strokes per minute may be attained. The spindles of rotary machines are usually speeded to make about 2000 revolutions per minute for working soft wood, and 1200 revolutions for hard wood. Fig. 11 represents a combined routing and squaring out machine, especially adapted for railway carriage framing, &c., from the designs of Messrs. George Richards & Co., Limited, Broadheath, near Manchester. The general arrangement of this machine can be readily gathered from the illustration. The table upon which the wood is placed has horizontal and vertical adjustments, and is fitted with a series of rollers, all geared together, which enables the wood to be traversed through the machine rapidly. Suitable stop pieces are fitted to the table, to regulate the position and width of the mortises. Passing to the boring machine (No. 20), this should be preferably a vertical multiple spindle machine carrying three or four spindles. The object of having multiple spindles is to avoid the loss of time in constantly changing the bits, through the holes in carriage work, soles, &c., varying considerably in size. The boring spindles should be mounted in a sliding bracket, having a transverse movement across the face of the main column, as this obviates the frequent shifting of the timber. For boring head stocks, sole bars, &c., the table is best mounted on rollers, and an additional standard with rollers should be placed about a yard from either end of the table for supporting long pieces. The rollers supporting the table may be driven by toothed gearing, and the table traversed, as may be desired. This plan of driving the table and the transverse movement of the boring bits will effect a very considerable saving over the ordinary plan, as the bits may be brought into action at any desired point on the face of the timber. The bits should make about 1500 revolutions per minute, and for rapidity of work a slightly modified form of the American screw auger will be found useful. The illustration (Fig. 14) shows a four spindle boring machine, specially designed for railway carriage and waggon work, by Messrs. Thomas Robinson & Son, Limited, of Rochdale. The head stock carrying the boring spindles is adjustable transversely, so as to allow of the position of the augers being quickly varied. The timber to be bored is fixed on the travelling carriage, which is traversed longitudinally by means of a rack and pinion gear. The double vertical spindle shaping and moulding machine, indicated on the general plan by No. 29, will be found extremely useful for interior carriage work, window sashes, &c., also for narrow planing and rebating. The spindles are arranged to rise and fall and revolve in opposite directions, so that the wood being worked can be passed from one spindle to another to suit the grain of the timber. Ordinary flat cutters shaped to the desired profile are usually employed, the wood to be shaped being mounted on a template to the desired form. The cutters are either mounted on blocks or secured between collars by means of end pressure. The latter arrangement is generally to be preferred, as sharper curves can be worked than with blocks. Where a large quantity of work of the same profile is required in lieu of blocks, solid steel saucer-shaped cutters may be used with advantage. In these the profile of the desired moulding is turned on the periphery of the cutter, which is sharpened inwards, certain openings being provided for that purpose. This form of cutter is much more costly than the ordinary flat cutters, but possesses the advantage that it never alters the shape of its profile, even if the sharpening is badly done. In using flat cutters, if any difficulty is found in keeping them all to the same profile, one cutter on each block may be dispensed with, its place being filled by a steel blank. Care must be taken, however, that the blanks and the cutters balance each other, or the work will be marked and irregular, owing to the centrifugal force set up. The cutters should travel about 5000ft. per minute. A considerable saving over hand labour in preparing panelling and similar smooth surfaces for varnishing can be effected by using a scraping machine, such as illustrated in Fig. 12, from the designs of Messrs. George Richards & Co. The wood is smoothed by means of a blade having a burred or turned edge, after the fashion of a hand scraper. The blade is held in a clamp, and the wood passed over it by feed rollers; the stock is pressed against the wood by an adjustable spring, and a light shaving is taken from its surface. It is necessary to the successful working of this machine that the scraping blade be ground perfectly straight on the face and bevel, and the scraper edge turned properly. This is accomplished by a machine illustrated in Fig. 13, the grinding being done by an emery wheel, the dust from which is removed by an exhaust fan. In establishments where large numbers of carriages are turned out, a self feeding sand papering machine for panels, &c., may be used with advantage. This consists of a modified form of roller feed panel planing machine—the rollers being covered with sand paper instead of cutter blocks. A cylindrical dusting brush for cleaning the wood is also fitted, and any desired pressure may be put on the sand papering rollers by means of hand wheels and springs; and the speed of the feed may be altered as desired. A very useful form of machine for sand papering work after it is put together is what is known as the flexible arm disc machine. This is usually hung from a wall bracket or separate column, and consists of a disc covered with sand

Digitized by Google

RAILWAY CARRIAGE AND WAGGON WORKS.

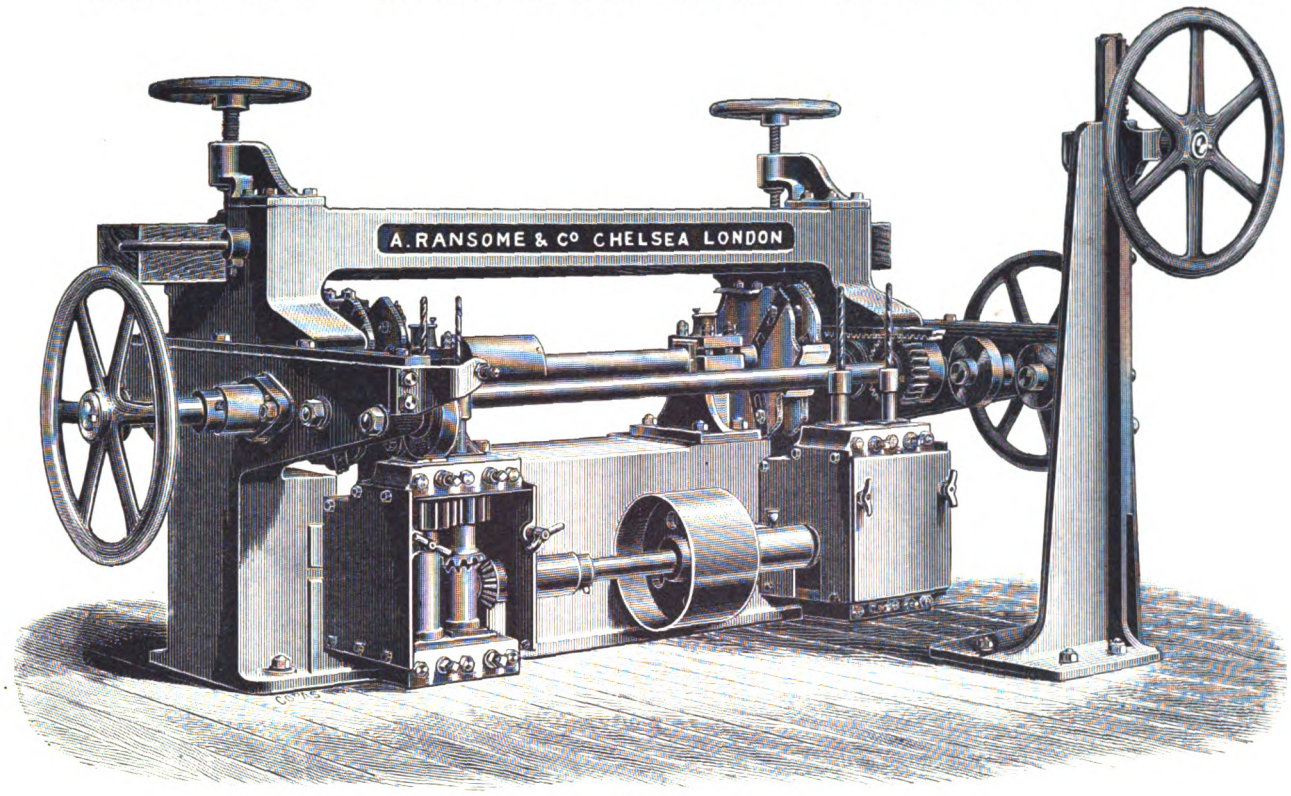

Fig. 10.

paper, which is made to revolve at a suitable speed. By means of several flexible arms or elbow joints the disc may be moved in any desired direction by the workman; the wood being placed on a table beneath it. The disc is made adjustable to different thicknesses of wood by means of a hand wheel and screw. A small exhaust fan is usually attached to the block which carries the sand paper disc, and rapidly removes all dust from the face of the work, and the operator is thus able to see at a glance when the right amount of finish is obtained. For short pieces or irregular work a plain revolving drum covered with sand paper, or an endless band covered with a composition, can be used.

All wood converting establishments should have a tool sharpening room, with a complete equipment of sharpening machines for circular, straight, and band saws, plane irons, &c. These should be placed under a man of the highest skill, who should be held answerable for the complete equipment and condition of all the cutting tools in the works, as it goes without saying that unless they are kept in what may be justly termed scientific order, the result is loss of power and wood, and a reduced output of inferior quality. The sawyers should not be allowed to sharpen their own saws, as it is generally found that each one of them has different ideas as to the proper method of performing that operation. Any judicious outlay in the tool and sharpening room is money well invested, as on it depends to a very considerable extent the successful working of the whole establishment.

Although not strictly within the scope of this paper, an important matter in railway economy is the manufacture of keys and treenails. Fig. 8 represents a powerful machine for compressing keys or treenails, designed by Messrs. John McDowall & Sons, of Johnstone, near Glasgow. In this machine the main spindle gives motion, by means of eccentrics, to two bars or rams which drive the keys or treenails into dies, and two bars which drive them out again when compressed. It can also be used for compressing parallel keys, which are driven through the dies one after the other at each stroke of the machine. When used for this purpose, the two return bars are removed. A slight modification allows the machine to deal with keys steamed under compression. In this case it is fitted with two bars for driving in and two bars for driving out the keys or treenails. The makers claim for this machine an output —when dealing with parallel keys—of some twenty per minute, and with keys steamed under compression about twelve per minute.

Fig. 10 represents a combined sleeper adzing and boring machine specially adapted for sleepers of very hard woods, designed by Messrs. Ransome & Co., of Chelsea. The sleeper to be cut is cramped by square threaded screw cramps to a cast iron carriage, running on large turned rollers, and capable of being fed over the cutter blocks by means of a rack and pinion motion, actuated by large

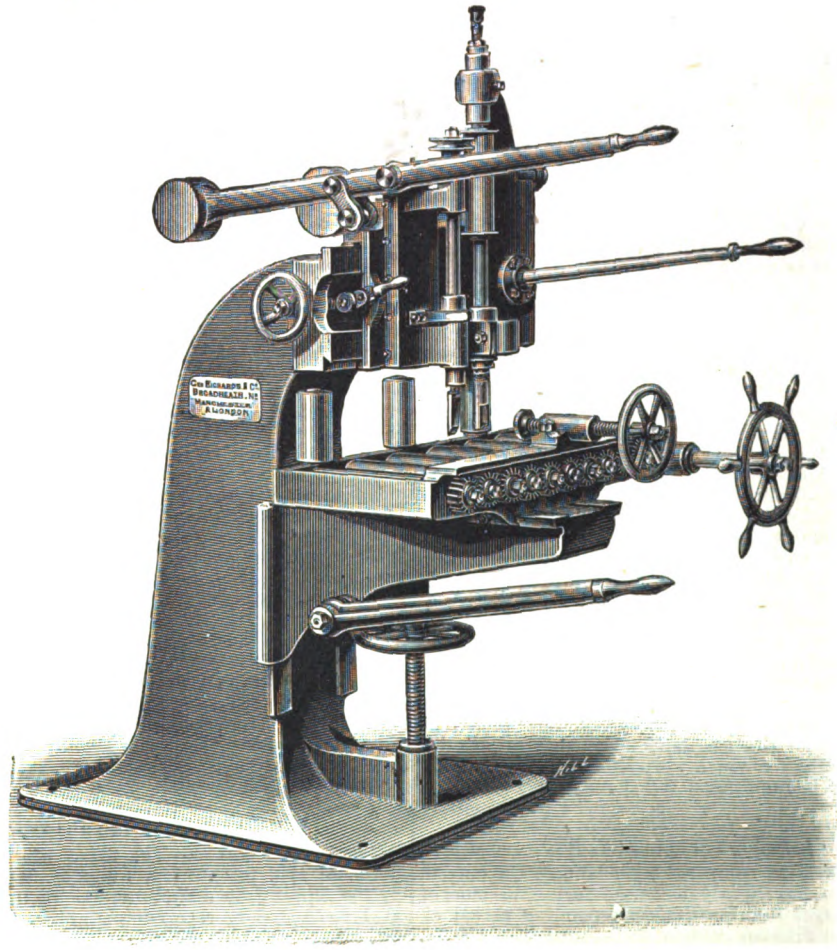

Fig. 11.

hand wheels, one on each side of the machine. The cutter blocks are of comparatively large diameter, and provided with three adzing cutters and six shoulder cutters. The main frame of the machine consists of a hollow box bed or standard of cast iron, carrying two side brackets for the rollers of the travelling carriage, and the saddles for the boring spindles. The boring spindles are of steel sliding in cast iron sleeves, and all four spindles are capable of being fed up simultaneously towards the sleeper by means of a rack and pinion motion, actuated by the hand wheel on the standard shown to the right of the illustration. The boring spindles are geared together in pairs, and driven by mitre wheels from a horizontal counter shaft attached to the machine. The whole of the gearing for driving the boring apparatus is cased in from dust and chips by cast iron covers. A transverse adjustment is provided for the cutter blocks and boring spindles, to permit a slight variation if required in sleepers used for curves. The reason the boring apparatus is fed through the wood by a hand wheel instead of having an automatic action is that with very hard wood any other system tends to break the augers.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 28TH FEBRUARY, 1888.

THE IRON MARKET.—The iron market still exhibits a tendency towards greater activity, and the recent rise in prices is easily maintained. In most cases the current rates are willingly paid, and in some great eagerness to buy is manifested. The events of the day also tend to strengthen the situation. The Belgian trade in finished iron and steel, which showed symptoms of declining vigour a few weeks ago, is again reviving. The negotiations in progress between the Northern group of iron masters and those of the Centre, relative to the establishment of a common scale of prices, appear to be on the point of arriving at a successful issue. The Paris market is fairly animated and buoyant. In the provinces business is still more animated. Plates are in strong demand in the Nord, wire and wire nails in the Haute-Marne, and crude iron, steel blooms and billets, and plates in the Meurthe-et-Moselle. The pig iron trade of the Longwy districts is very animated. The latest "Comptoir" prices are as follow: White forge pig, 38s. 5d.; grey forge, 40s. 10d.; basic steel pig, containing from 1·50 to 1·75 per cent. of manganese, 45s. 7d.; foundry pig, No. 1, 54s. 5d. The Société des Aciéries has blown in another blast furnace for basic steel pig this week.

A WAR OF TARIFFS WITH ITALY.—French industries seem about to suffer from a violent disturbance of the commercial relations hitherto existing between France and Italy. The refusal of the Government of the latter country to renew the treaty of commerce has provoked a spirit of retaliation, which is likely to lead to a serious issue. The Commission of Customs, under the presidency of M. Méline, has completed its inquiry into the proposals of the Government concerning a new tariff designed to meet the increased duties imposed by Italy on French goods. This Commission has raised the Government figures considerably on a large number of articles. The matter is of great importance to the trade of Europe.

EXHIBITION OF LIFE SAVING APPARATUS.—The international exhibition of apparatus for the saving of life, to be held this year in the Palais de l'Industrie, is likely, judging from the numerous and varied applications for space, to be one of very great interest. The scope is wide, including land, sea, and air. Not the least important section will be that which deals with the saving of life in mines. This exhibition, and that which is to follow it in 1889 at Berlin, of apparatus for the prevention of accidents, should do something towards lessening the risks of those who are engaged in hazardous occupations. Anyhow, the occasion is one not to be lost sight of by inventors who have designed a new device in this line.

FALL OF AN IRON BRIDGE.—The fall of the iron bridge, known as the Pont d'Arcole, at Paris, is a matter of interest to engineers. It was one of the first iron bridges built in France, and consisted of a single arch of 90 metres span, its breadth being 20 metres. At the time of its erection, in 1851, the science of iron bridge building was in its infancy: but even at that period doubts were entertained of the stability of the structure.

THE PARIS OPERA COMIQUE.—The plans for re-building the Opera Comique, which was burnt down nearly a year ago, have been elaborated by the French Government, and copies have been distributed among the deputies. According to this project, the theatre is to be re-built on the same site; but a piece of adjoining land has been acquired which will allow of large exits being made at the four corners of the theatre. The total cost is estimated at £139,200, which, after deducting the amount paid by the insurance companies as indemnity for the burning of the previous theatre, and the amount realised on excavated material, will be reduced to £96,552. The stage will be provided with independent staircases, while the actors' dressing rooms and store rooms on either side of the stage will be so constructed as to form an incombustible barrier between them and the auditorium. The staircases for the use of the *personnel* of the theatre will be easy of access, and in direct communication with the two adjoining streets. The building will be heated by low pressure steam, the boilers being placed under the vestibule. The theatre will be lighted electrically, for which purpose from 1800 to 2000 glow lamps will be required.

BERLIN, 27TH FEBRUARY, 1888.

COAL MARKET.—As compared with January the output of most collieries has slightly decreased during this month, but it is still larger than at the corresponding period of last year. The Silesian colliery owners recently met at Breslau to discuss the question of transport facilities, which at the present moment are sadly inadequate. There is a great lack of waggons, and orders cannot be executed with sufficient speed. At the conference in Breslau the general opinion was that the coal trade would remain brisk during the whole of the year, and that an increase of from 5 to 10 per cent. in the rolling stock would be required to meet the demand. Coking coal and coke are in strong demand at hardening prices. Various collieries have made contracts with railway companies and private firms for the supply of coal throughout the year, and in some cases at prices somewhat higher than ruled in January. A slight reduction in the tariff for coal will come into force on the State railways on the 1st of April next.

THE IRON MARKET.—The Upper Silesian iron market continues unchanged. Crude iron, both for puddling and foundry purposes, continues in good demand, and the blast furnaces are hardly able to keep pace with present requirements. A few weeks more of this condition of affairs will necessitate the blowing in of several new furnaces. Steel works are also well employed, and the spring season for boiler works, engineering shops, and pipe makers is likely to prove good. The falling off in the quantity of rolled iron sold during January has been more than counterbalanced by increased sales in the present month, and all rolling mills are now working full time. In joists and other building iron the demand is exceptionally brisk. Generally speaking, little is done in building iron during the winter; but this year orders have come in so abundantly that stocks have been cleared out, and manufacturers of that class of iron are hardly able to supply the demand. Forge pig is quoted at from 50s. to 54s., and foundry pig from 56s. to 58s., whilst scrap iron has slightly declined in price. A rise of 2s. has taken place in the price of sheets, which are now quoted for local consumption at 160s. to 165s. Bar iron is firm at 140s., and profile iron at 155s.

ELECTRIC TRAIN LIGHTING.—Experiments have been in progress on the Alsatian State railways since the beginning of the year with electrically lighted trains, the current being supplied by small storage batteries carried under each coach in lieu of the gas reservoir. Each battery consists of 36 cells, carried in a tray for facility of handling. These batteries are charged at some of the stations which already have electric lighting plant, the intention being to utilise this plant during the daytime. The capacity of the battery is 40 ampère-hours, and the cells are small ebonite boxes containing plates of novel construction. Instead of the usual perforated grid, each plate consists of a rectangular lead frame, containing a number of vertical lead pencils about ¼in. diam., which at every half inch are widened out into thin discs about ⅜in. in diameter, and the grid of pencils and discs thus formed serves to support the active material. The plates are necessarily much thicker and heavier than equivalent plates of the usual construction. Each coach is lighted by five 10-candle 60-volt Seel lamps, requiring from 5 to 6 ampère. A small rheostat is added in front of the battery tray, by which the conductor can regulate the light. The illumination is much better than was previously the case when the train was lighted by 5 c.p. gas lamps. The trains were fitted by the Alsatian Electric Works, of Strasburg.

ELECTRIC LIGHTING.—Messrs. Siemens & Halske have been experimenting for a year and a half with the secondary battery of Herr Epstein, and under the inventor's supervision considerable improvements have been made, not only in the mechanical construction of the plates, but also in the process of forming them, which now requires four hours instead of several days as formerly. The forming is facilitated by the treatment of the plates in certain baths. It is evident that the makers must now have considerable confidence in these plates, since they are fitting up a set of accumulators in the Central Hotel in this town, which is at present supplied with current from the mains. This will be the second instance in Berlin where accumulators are used in connection with central station distribution.—The town of Bremen is also on the point of receiving a central station; the contractors are the Allgemeine Elektricitats Gesellschaft, but the work will be done by Messrs. Siemens and Halske. A very curious contract has been made between the company and the Town Council of Bremen. Upon payment of a toll or fee to the Town Council of 1s. per annum per lamp attached to the central station, the company have the right of carrying their mains over the houses or under the streets, and in any manner they may think proper. Practically the company have for this small toll secured the sole and undisturbed right of way for running their circuits. Consumers pay ·57d. per 16 c.p. lamp-hour. The supply will be on the parallel direct system at 100 volts, and the capacity of the station is to suffice for 10,000 lamps. The districts to be lighted are not extensive. Consumers find their own lamps and pay for the installation, but the company will refuse to supply current to any consumer who has not employed Messrs. Siemens & Halkse for the wiring and fitting up of his premises. In Hamburg the company have also a small central station supplying 1500 glow lamps and some arc lamps. A second and much larger station is projected.

VIENNA, 27TH FEBRUARY, 1888.

THE IRON MARKET.—The event of the week is the purchase of a private iron works in St. Michael, Styria, by the Alpine Iron and Mining Company. The company, as I have already reported on previous occasions, have hitherto always been more or less in financial difficulties, owing to their being burdened with large tracts of forest land, which, although valuable to their industry in previous years, are now, owing to improved methods of smelting iron, almost useless. The directors have therefore resolved to pursue a policy of reform, and the first step has been the sale of some of the mining and forest land. The proceeds of the sale will be expended in re-modelling their plant in accordance with modern requirements, and the purchase of private works forms a part of the programme. No change of any importance has taken place in the iron market. The rise of 7s. in the price of bar iron, which I reported last week, has had the effect of stimulating rather than checking consumption, and dealers, apprehending a further rise, have come into the market and placed considerable orders. There is as yet no sign of any improvement in crude iron; but sheets are in fair demand, and a considerable business is also being done in furniture. In Bohemia, there is a good demand for agricultural implements, such as spades, picks, hoes, &c. Engineering works are fairly well supplied with orders. Rolling mills are said to be contemplating a rise in the price of girders and profile iron for building purposes. In Hungary, there has also been a slight revival, consequent upon the increase in the price of bar iron. A fair demand exists for boiler plates, but sheets are neglected. A rise in the price of wire nails was confidently expected, but has not yet taken place.

TEXTILES.—The firm tone of the linen and yarn market in Trautenau, which I reported in my last letter, has been fully maintained during the past week. The improvement is not so marked in wool, cotton, silk, and jute. There is a slight tendency to better prices; but this cannot assert itself, owing to the want of confidence in the political situation on the part of spinners and weavers.

RAILWAYS IN AUSTRIA.—The total mileage of steam worked railways throughout Austria (exclusive of Hungary) is about 8500 miles, being at the rate of 1 mile per 2000 inhabitants. These lines are owned by fifty-six separate owners, of which forty-six are private companies, five are joint administrations with foreign railways, and five are under State administration. The network of Austrian railways has forty-four junctions with foreign countries, and eleven junctions with the Hungarian system.

THE MERCANTILE FLEET OF AUSTRIA.—The present position of Austrian shipping is by no means cheering, showing a diminution not only as compared with last year, but even with ten years ago. This decrease falls exclusively to sailing tonnage. At the end of 1887 there were trading 9235 Austrian vessels, giving employment to 27,209 persons. The steam power of this fleet amounted to 24,163 h.p. At the end of the previous year the figures were 9252 vessels, 27,586 persons, and 23,598 h.p. The decrease in the number of vessels and the increase in horse power show the present tendency to supplant sailing vessels by steamers. There were 219 vessels engaged in trading over long distances, representing an aggregate of 17,555 h.p.; eighty-seven vessels, with 5405 hp, were engaged in long distance coasting trade; and 155 vessels, representing 1203 h.p., were engaged in short coasting voyages. Ten years ago 409 vessels traded over long distances, sixty-one were long distance coasting traders, and 1658 were short distance coasting traders. A glance at these figures will show the reason why Austrian shipbuilding is in its present depressed condition. In the sixteen shipbuilding yards, having an aggregate of twenty-nine stocks, the total tonnage built during 1887 was less than 2000 tons. There were built and launched during the year twenty-one sailing vessels, 180 barges, and three steamers. The average price obtained for the last was about £31 per ton.

BRUSSELS, 28TH FEBRUARY, 1888.

THE COAL MARKET.—Prices are firm, but the stoppage of canal navigation, and scarcity of railway rolling stock, make it a matter of difficulty to forward consignments of coal. Orders are being given by the Government railways for 335,000 tons of coal, and blast furnaces are desirous of renewing their contracts, which expire on the 31st March. In the Mons district there has been a rise both in household and industrial coal. Contracts for future delivery in the Liège district also show an advance, and the Charleroi market is very satisfactory. Owing to the high Belgian railway rates, a Hainault colliery is finding it impossible to compete in the Grammont market with French coal; but the request for an abatement of 10d. per ton has been refused by the Belgian State railway management. The production of coal during the second six months of 1887 amounted to 9,480,853 tons, as compared with 8,810,677 tons in the corresponding period of 1886. The total production of 1887 amounted to 19,216,031 tons, as compared with 17,235,144 tons, an increase of 1,980,887 tons.

THE METAL MARKET.—The price of forge pig shows no tendency to weaken, and the disproportion between these rates and those for finished iron continues. The market generally is unchanged. The contracts for five hundred 10-ton coal trucks for the Belgian State railways have resulted as follows: Trucks with spindle brakes—The Société Franco-Belge, La Croyère, fifty trucks, £4,450; Dyle & Barcalau, fifty trucks, £4,494; Germain & Co., fifty trucks, £4,508. Trucks with Stilman brakes—Lambert and Co., fifty trucks, £3,748; Halot, of Louvain, fifty trucks, £3,758; Vanderpepen, of Mons, fifty trucks, £3,768; Société Haine, of St. Pierre, fifty trucks, £3,774; Noulet & Co., fifty trucks, £3,796; Baume & Marpeut, fifty trucks, £3,784, and fifty trucks, £3,846. A vote of credit will be asked shortly for the Meuse fortifications, and the specifications for the steel armour required will shortly be issued.

GLASS WORKS.—A meeting of glass manufacturers has been held to consider the present crisis in the trade. This is due to the fact that fuel is dear, consequently the margin of profit at the present low price of glass is becoming daily less. A special brand of coal raised in the Mons district is, it appears, indispensable to the glass makers with their present plant, and as the prices for this coal continue to advance, some of the less prosperous glass works will probably have to cease work, unless all the makers can come to an understanding by which the prices of glass ware can be forced up. There is no change in the prices of glass, the rates for England being 19s. for coarse, 21s. for

Digitized by Google

fourth, and 23s. for third quality. The *four-à-bassin* of M. C. Lambert has been installed at the La Planche works, and has given excellent results. The length of the furnace has been diminished and the width increased, in order to reduce the first cost of the plant. The furnace is also 6ft. high, against 3ft. 6in. or 4ft., as customary in the old construction. Gas and air are not mixed before ignition in a special chamber, but are carried separately up to the edge of the basin by parallel conduits, terminating in a special burner, giving a long and regular flame. The saving in fuel over the old furnaces is about 25 per cent.

Electric Lighting.—A committee has been formed to take the initial steps in connection with the electrical syndicate to which I recently referred, and consists of M. Van Rysselberghe representing Mourlon, M. Julien for the Société l'Electrique, M. Gérard for the Anspach-Gérard-Mignot combination, M. Goffin for the Société Industrielle, and M. Bonnevil for Bouckaert & Co. This committee has drawn up two proposals to be submitted to towns desirous of obtaining tenders for electric lighting: (1) The erection of central stations on the alternating current system with transformers, and (2) the erection of stations for the supply of high tension continuous currents and secondary batteries. In the first case the dynamos of the Bouckaert and Industrielle Companies and Goffin-Hohe transformers would be used, and, in the second, Gérard dynamos and Julien accumulators.

DÜSSELDORF, 27th February, 1888.

The Iron Market.—The home business in iron is still characterised by animation and advancing prices; but it cannot be expected to preserve these features much longer in the face of a steadily decreasing foreign trade. For the present manufacturers revel in the prosperity born of trade combinations, and leave to the future the unpleasant reckoning which the loss of foreign markets must inevitably bring. There is not much that is new to report concerning the crude iron market. Nearly the whole of the make in the first half of the current year is placed, and contracts are being made for delivery in the third quarter. The prices paid are in all cases above the syndicate minimum. Despite the present high rate of production, and the falling off in the exports of pig iron, the January trade resulted in a further diminution of the stocks. Forge pig is less sought after, but spiegel is in strong demand. Both forge and spiegel is being largely bought on French account, in anticipation of the abolition of the traffic in *acquits-à-caution*. To meet this demand for immediate delivery prior contracts have had to be deferred. Luxemburg forge is now quoted at 40s. Foundry pig is in better demand; other sorts remain unaltered. There is no change to note in the finished iron and steel trade. A rise of 2s. 6d. a ton in bars is expected. Business in common plates is less active. The production of plates by the works of the West of Germany Union in January amounted to 9121 tons, against 8339 tons in December. The following are Cologne prices: Spiegel pig, of 10 to 12 per cent., 58s. to 60s.; German Bessemer, 54s.; white forge pig, 54s.; Luxemburg forge, 38s.; German foundry pig, No. 1, 57s.; merchant bars, £6. 2s. 6d. to £6. 5s.; angles, £6. 12s. 6d. to £6. 15s.; joists, £5. 18s. to £6; best boiler plates, £8. 5s., and Siegen H K plates, £7. 10s. to £7. 15s. per ton. The production of pig iron in January amounted to 346,962 tons, against 293,879 tons in the same month of 1887.

The Linen Yarn Market.—The linen yarn market is this week characterised by more activity. Spinners show a disposition to buy. The demand is brisk for tow yarns, and prices have become very firm.

The Flax Spinning Industry.—The flax spinning mills in and around Bielefeld are now running full time. The demand for yarns has been steadily reviving for some time past, the coarser numbers being most sought after. The stocks in hand are being heavily drawn upon, and orders rapidly booked for future delivery. The business of the year 1887 was on the whole satisfactory, and 1888 promises to be better.

Railway Receipts.—The expanding tendency of trade is seen in the railway receipts for last year. The report of the Budget Commission states that the receipts for the passenger traffic amounted to £9,397,000, an increase of £512,500 on those of the previous year, while the goods traffic yielded £25,026,050, an increase of £1,420,500.

LILLE, 28th February, 1888.

Textile Manufactures.—Business in textile goods is still wanting in life. The heavy snows of the last two weeks have no doubt contributed something towards the quiet which prevails, so that we may expect a revival with the return of more genial weather. There are already signs of approaching activity in the linen goods trade of Armentières. The situation of the woollen goods trade has not improved, but rather grown worse. Some of the Roubaix weavers have put their mills on short time. Spinners complain of a lack of orders, having scarcely sufficient in hand to keep their works going. Raw wool, in sympathy with the London market, has receded a little in price. Australian combed is fairly firm at 5·65fr. to 6fr. per kilo. South American wools are lower by 0·15fr. There is some animation in the market for "noils." South American sells at 3·10fr. to 3·30fr., and Australian at 3·50fr. to 3·80fr. per kilo.

Flax and Yarn Markets.—Home grown flax continues to find ready purchasers at prices that tend steadily to advance. The decline in the rate of exchange having enabled sellers to offer some concession in prices, more business is being done in Russian produce. The dealings have been mostly for future delivery. Tows are less inquired after. Business in yarns has become less animated; but as spinners have heavy contracts on hand, they trouble themselves but little concerning the present state of the market. Jute yarns are still in good demand, and prices are in favour of sellers. At Ghent there are indications of weakness in the market for flax. The values of the yarns exported in 1887, compared with those of the preceding year, are as follow: Woollen yarns, £1,540,320 (£1,755,840); flax and hemp yarns, £412,360 (£242,400); cotton yarns, £100,200 (£76,120); jute yarns, £53,920 (£70,040).

The Import Trade in Wool.—The imports of wool from La Plata through Dunkirk shrank to a relatively small total in the latter months of last year. The falling off, however, is of only temporary significance, being due to the fact that the abolition of the duties levied on all goods exported from the Argentine Republic came into force on the 1st January of the current year, a circumstance that occasioned the delaying of as much business as could be conveniently postponed. Large quantities of Algerian wool have lately arrived. Besides the steamers of the three regular lines between the French colony in Africa and Dunkirk, several foreign vessels, accepting lower freights, have brought cargoes shipped at Algiers and Philippeville.

The Iron Market.—Though the business in iron has been marked this week by somewhat less animation, the market has lost none of its firmness. The demand for bars and joists has somewhat decreased, but buying goes on briskly in common plates. An advance in the prices of this latter class of goods is expected, and may be announced any day. Manufacturers are very firm in their demands from customers who buy for home consumption; but concessions are made to foreign purchasers. In anticipation of the date when the traffic in *acquits-à-caution* is to cease, manufacturers of the Centre and South are buying largely, chiefly from the German producers. The consequence to this district is that considerable quantities of pig iron of foreign origin find their way into the hands of consumers.

AMSTERDAM, 28th February, 1888.

The Mail Service in the Dutch East Indies.—The Second Chamber of the States General has passed the Government Bill, authorising the Governor General of the Dutch possessions at Batavia to sign a contract with a national syndicate, providing for the establishment of a new and subsidised mail service between Java, Borneo, Sumatra, New Guinea, and all other important islands of the Indian Archipelago. The syndicate will transfer its rights and privileges to a new company, still to be formed. The contract is for fifteen years, commencing in 1890. The Bill has a very important bearing upon British shipping, which will be virtually excluded from the steamship navigation between the Dutch-Indian islands. Hitherto the monopoly has been in English hands, as the Netherland-India Steamboat Company, which holds the existing contract for the mail service in those seas, was only nominally a Dutch, and in reality an English undertaking, with English directors, English shareholders, and registered offices in London. Political reasons have induced the Dutch Government to abolish the system of public tenders for their Indian mail service, as they were determined to give the contract to a Dutch company. All the directors, and the captains and crews of the mail vessels, must be Dutch subjects. Moreover, the concessionaires are to have these vessels constructed in Holland, as far as possible. There have been protests against the strong protectionist character of the contract; but the Government have carried the day, and there is no doubt that the First Chamber of the States General will likewise sanction the Bill.

NEW YORK, 18th February, 1888.

The Coal Market.—The coal market is practically unchanged, and the statement that the miners' strike has received the approval of the Executive Committee of the Knights of Labour, and that 15 per cent. advance would be demanded in the Wyoming region, has so far had no effect on the market. The shipments of coal show an increase. The supply is now ample.

The Iron and Steel Market.—The pig iron market is still unsatisfactory, and there is a decided falling off in the demand. Prices are unchanged. This year's output will probably not exceed 6¼ million tons, while the productive capacity is about a million tons in excess of this. Higher prices are unlikely, and a 5 per cent. decline would probably reduce the production of iron and steel by from 10 to 15 per cent. The bar iron market is moderately active, but with no improvement in prices. Orders are for small lots, and most of the work in hand can be finished in a week or ten days. Prices are two cents per lb. for refined bars, but large orders can be placed at 1·9 to 1·95 cents. The steel rail market retains its firm tone, but has not shown the activity expected. Sales in small quantities are made at $32 per ton, and larger orders are placed at $31·50. Domestic steel makers will not increase the allotment of 800,000 tons until the market shows an improvement. The total contracts for the year amount to about 500,000 tons. The miners' strike and the small amount of business in steel rails have had a prejudicial effect on the blast furnaces, of which there were on the 1st inst. only 313 in blast with a weekly capacity of 127,166 tons, a reduction of 10 per cent. of the number in blast a year ago. There are 274 out of blast, of a weekly capacity of 75,085 tons.

The Metal Market.—The copper market has changed but little; sales somewhat below the average have been made, with prices varying from 16·35c. to 16·55c. per pound for present delivery. In lead, sales, partly speculative, have been made to the extent of 1400 tons, at 4·90c. to 4·95c. per pound. Stocks of tin are small, and there is only little business transacted.

Railway Car Building.—This branch of engineering is brisk, and one leading car builder has already made contracts for the entire capacity of his works during the present year, and has been compelled to decline an order for 1200 cars.

Ship Building.—Messrs. William P. Clyde & Co. have given an order to Cramp's shipbuilding yard for a new steel steamship, which will be 300ft. long, 46ft. beam, and over 3000 tons burden. She will be fitted with triple expansion engines and steel boilers, and will run between New York, Charleston, and Jacksonville.

Salt Supply.—A report has been published by the superintendent of the salt reservation at Syracuse, from which it appears that the total number of bushels inspected during the year 1887 was 5,695,797, of which 2,576,823 were of fine salt. The production has during the last forty years sometimes been as high as 9,000,000 bushels, with an average of 7,000,000. The report states that the sinking of two wells for the purpose of discovering beds of rock salt was a failure. One of the wells reached a depth of 1600ft., and the other 2000ft. This is not of itself discouraging, as at Ithaca 2270ft. had to be bored before the 50ft. bed of rock salt was reached. The salt bed of Western New York extends about 120 miles from east to west, and about forty to fifty miles from north to south. The area of the salt bed territory is nearly 5000 square miles, and the average thickness is 40ft. This means that the supply is practically inexhaustible.

PHILADELPHIA, 18th February, 1888.

Railways.—The revival of the South Penn Railroad project is the most interesting event that has taken place in Eastern railroads for some time. The road is to run from Harrisburg to Pittsburg, and is intended to compete with that portion of the Pennsylvania road. Considerable work in tunnelling and preparing the road bed had been done when the original owners sold the property to the Northern Central, the negotiations being conducted and payments made by the Pennsylvania. As it is contrary to law in this State for one road to buy up a competitor, the Attorney-General brought an action to have the contract declared illegal, and this suit is still pending. Last July it was proposed by the Vanderbilt interests and others to go on and build the road. The Pennsylvania road have filed a bill in equity praying for an injunction against the construction of the line until the ownership of the property is settled. It is expected that active work on the road will begin as soon as the weather is open enough. The line has been examined by engineers, and found to be in good shape, very little damage having resulted from its abandonment. The contracts with the Reading road and other connecting roads are still in force.

The Baldwin Locomotive Works.—These works have recently completed their nine thousandth engine. The works were not originally laid out for building modern locomotives, and they labour under some disadvantage in consequence. The different shops are separated by public streets, and many of them are at a considerable distance from the main office. From a small beginning the Baldwin works have built up by far the largest business of the kind in the world.

Wrought Iron Pipes.—This industry is beginning to feel the bad effects of over production. Within the last eighteen months production has increased over 100 per cent., and now amounts to over £4,000,000. The prosperous condition of the business a year and a half ago induced new parties to enter the business, and new mills were started at Boston, Oil City, Wheeling, and Pittsburg, while the old mills increased their production enormously. The result is that there is not market enough to take up the output of both old and new mills.

Locomotive Check Valves.—The Pennsylvania Railroad are fitting an inside valve on their boilers, so that if by an accident the check valve chambers are broken off, the valve will close and prevent the escape of the water and steam. The utility of this arrangement has already been shown in the case of a slight accident lately, where the locomotive ran into the side of a passenger car and the check valve chamber was broken off; but no injury by scalding took place.

Natural Gas for Glass Furnaces.—Wherever it is available, natural gas is being used in glass furnaces with excellent results. It is an improvement in every way, and not only lessens the cost of fuel, but does away with the labour of attending to the furnaces. It also improves the quality of the glass produced, as the intensity of the heat, which can be regulated at will, allows a perfectly uniform temperature to be maintained, and thereby lessens the time required to do the work. In the case of flint glass the time is reduced from thirty-six hours to twenty-four hours, and in all kinds the saving of time is never less than four hours.

TELEGRAPHS IN JAPAN.

The rapid progress which has been made in Japan during the past few years is not realised by those who have not been to that country, at least to the extent that it should be. The Japanese are ambitious of making their country the Britain of the East, and it seems to be in a fair way of fulfilling their wish, at least if we may judge from the rapid extension of their telegraph system, which is shown in the following table:—

Year.	Population.	Number of telegrams.	Average number of telegrams per thousand of population.	Total receipts.	Average receipts per thousand of population.
				Yen.	*Yen.*
1872	33,110,825	80,639	2	10,255·55	0·31

* No census having been published in 1877 and 1878, the figures for those years are incomplete.

Also graphically in the accompanying diagram, while the general arrangement of the telegraphic system of Japan was shown in the map we published in Vol. I., page 112. The following particulars have been extracted from the twelfth report of the Director-General of the Imperial Government Telegraphs which has just reached us, and

Number of Telegrams.

which contains a considerable amount of interesting information regarding the development of the system, and statistics regarding the different localities, which, however, are of no special value to readers in this country. We will, therefore, only note a few of the items of more general interest. During the year 1885-86 the total length of new lines—telegraphic and telephonic—which were constructed was 166 miles 1264 yards, involving a length of wire of 397 miles 1728 yards, which is a very fair rate of progress indeed. The total length of telegraph and telephone lines at the close of the fiscal year 1885-86 is given in the table at the head of this page.

An account is given in the report of the International Telegraph Conference, at Berlin, in August, 1885, at which the Director-General was present as delegate from Japan, and during the proceedings he made several good suggestions for the improvement of international telegrams. For instance, under the London revised regulations, a telegram consisting of only an address, without any text, was admissible. Such telegrams could, of course, be made the subject of pre-arrangement between the sender and the receiver, and would consequently have a meaning to them, although no actual "message" was transmitted. Much inconvenience arose from such messages, as the receiving office did not know when the message had been omitted, and when it had not been intended to be sent, and the resulting inquiries caused both trouble and expense. It was therefore suggested by the Japanese delegate that no telegram should be omitted which did not contain at least one word of text. This suggestion was seconded by several delegates, and after long debate it was determined that the question of allowing or disallowing telegrams without text should be left to the option of each administration, with the proviso that although each administration might refuse to accept no text telegrams from the public, it should nevertheless accept them from other administrations either for transmission or delivery. Another arrangement suggested by the Japanese delegate was the relaxation of the regulation that words containing more than ten letters were to be reckoned as two words, in so far as names of places of destination were concerned, and this was adopted by the Conference. The most important suggestion, however, made by him was that referring to the rule whereby an ordinary telegram when delivered, with no matter how many errors or omissions of words, was considered "delivered," and no question of refund on account of such errors or omissions was entertained. This was the old rule when there was a fixed charge for messages of twenty words. Since the regulations as to a single word rate have come into force, however, it appeared to the Japanese delegate to be only fair that when one or more words were omitted from a telegram, the charges paid for these words should be refunded, and he made a proposition to alter the regulations in accordance with these views, and it was accepted by the Conference. Lastly, although Japan's necessities require more expense to train her operators in foreign languages, and to obtain instruments, apparatus, &c., from abroad, and she is, therefore, comparatively not in a position to sustain loss, yet she proposed to decrease the rate for telegraphic traffic between Europe and Japan by 25 per cent. To this proposition, in its full extent, many companies objected; but, they being willing to accede to a reduction of 15 per cent., this compromise was adopted by the Conference, Japan also determining to lower her own rates in the same proportion. We mention those matters to show that the sending of a delegate from Japan to a European conference is no mere formality; and further, that that delegate looks after not only the interests of his own country, but also of the whole trading community.

The following table shows the number of foreign residents in Japan, including Chinese:—

Tokio	285
Osaka	271
Kanagawa	3762
Nagasaki	866
Niigata	31
Hakodate	84
Hiogo	844
Total	6143

It ought to be mentioned that Kanagawa is in reality the official name for the district usually called Yokohama.

THE PHYSICAL SOCIETY.

At the meeting of this Society held on the 25th inst., the first communication was a note by Professors Ayrton and Perry on "The Efficiency of Incandescent Lamps with Direct and Alternate Currents." The communication was made by Professor Ayrton, who prefaced it by pointing out that for economical distribution it was necessary to send the current through the mains at high e.m.f., and to adopt some system of transformation. The earliest attempt to effect this was by means of motor dynamos; then followed Sir William Thomson's method of charging accumulators in series, and afterwards dividing up the accumulator into groups and using them separately for the lamp circuits. After this came the Jablochkoff alternate current transformer, and finally Edison's system of direct current transformation.

The problem treated was to determine whether more light would be obtained for a given expenditure of power by the use of direct or alternate currents. In carrying out the experiments the light given out by the lamp was compared with a standard candle by means of a divided paraffin disc photometer. In order to eliminate the effect of irregularity in the amount of light from the candle, readings, with direct and alternating currents, were taken alternately in quick succession. The potential difference between the lamp terminals was measured by means of a voltmeter of the improved Cardew type, recently described by the authors at a meeting of the Society of Telegraph Engineers. The product of the readings of the voltmeter and the dynamometer would give the "measured watts," and the time watts were obtained by multiplying with $r\tau / \sqrt{L^2\pi^2 + r^2\tau^2}$, where r is the resistance and L the co-efficient of self induction of the dynamometer, and τ is the period of alternation.

The first experiments were made with Edison-Swan lamps, in which the filament is in the form of a loop, and this might introduce an error through self induction. Another error also occurred in these experiments from a metal box used for the damper of the dynamometer causing induction. These experiments were therefore rejected, the metal box was replaced by a wooden one, and Maxim-Weston lamps, having **M** shaped filaments, and lamps with simple horseshoe filament, were used. In either case there would be no appreciable self induction. The experiments were made both with ruby red glass and with green glass, and the result of seventy-five observations gave for the light from a lamp—with direct currents, 3·3989 watts per candle; with alternate currents, 3·3955 watts per candle. The difference between these is within the limit of errors of observation, so that as far as these experiments go the conclusion is that the same power (properly measured) will give the same amount of light, whether the currents are direct or alternating. The speed of alternation in the experiments varied from $\frac{1}{40}$th to $\frac{1}{150}$th of a second, but no difference was observed in the light.

Mr. Swinburne did not think that there would be appreciable self induction in an Edison-Swan lamp with any current less than 400 or 500 ampères. He found different dynamometer indications for the same amount of light with direct and alternate currents, and thought that the capacity of the filament for heat would have some effect.

Professor S. Thompson had, by moving a mirror backwards and forwards in front of a lamp, observed periodic variations in the intensity of the light obtained from alternate currents; but the period was much longer than that of alternation, and was, no doubt, due to a want of symmetry in the armature or the field magnets, either of which, as he had formerly pointed out, would give rise to a variation in the e.m.f. of a period equal to that of rotation of the dynamo. He thought it was of great importance that attention should be directed to the improvement of photometers, none of which were satisfactory. For example, in the one used the curvature of the waves falling on the disc would change when the position of the disc was altered, so that when the illumination was balanced at the centre it would not be so at the edges. He pointed out that a great objection to standard candles is that the light varies with the length of the wick. This, however, does not apply to the present results, as they can be made in such a way as to eliminate the effect of any irregularity. Supposing the light of a lamp supplied with alternate currents to vary periodically, we should have to consider how the eye integrates the impression received. Fechner's Law, though in general giving approximately true results, may not apply to rapid changes.

Professor Ayrton considered that the different dynamometer indications for the same light observed by Mr. Swinburne for direct and alternate currents were probably due to errors in the dynamometer. Captain Cardew had observed the same thing and mentioned it to him, and he pointed out that whereas the dynamometers usually made are constructed of thick wire to minimise the loss of energy, the one which they had

Digitized by Google

used in these experiments had been constructed with very thin wire, as in this case what was required was great accuracy, the waste of power being of no importance. Professor Perry, in reply to Professor Thompson's remark as to the slope of temperature from the inside to the outside of the filament, stated that in 1874, in consequence of a letter to *Nature* calling in question Dr. Macfarlane's results on the radiation of copper spheres, on the ground that the internal conductivity of the copper had not been allowed for, he investigated the question with great care, and found that it would have no effect, and he believed it would be the same in the case of the filament.

The Hon. Ralph Abercromby then read a paper entitled "Observations on the Height and Length of Ocean Waves." He pointed out that much better results could now be obtained than formerly, owing to the improvements in aneroid barometers, which will now measure height within one or two feet, whereas it was necessary formerly to climb the rigging until you could see two crests in line, and the time can now be observed by means of a chronograph without looking at the instrument when making an observation. The observations described in the paper were made two years ago in a steamer between New Zealand and Cape Horn. The length and velocity were determined by standing in the stern of the vessel with a chronograph and taking the interval between the passage of two successive crests, and also the times of passage past the stern and the bow. The table below gives the results of the author's observations, compared with those noted by other observers:—

Observer.	Maximum height.	Maximum length.	Maximum velocity.
Abercromby	35	507	39·5
"	46	765	47·5
Ross	23	1902	90
Scoresby	42	—	—
"Challenger" observations	23	—	—

The distances are in feet, and the velocities in feet per second.

The discrepancies in the results the author attributed to the difficulties introduced by the superposition of smaller undulations on the larger ones. The author always made his observations only when he could see two or three waves of about the same size coming in succession. If the distance between only two maxima are taken as the length of a wave, such enormous lengths as those given by Ross are often obtained. The velocity given by Ross is also much greater than any observed by the author.

THE LISTOWEL AND BALLYBUNION RAILWAY.

The opening ceremony of this railway took place on Wednesday last, in the presence of a number of distinguished visitors and well known engineers. The railway is the first constructed in Great Britain on the Lartigue single rail system, which was described in *Industries* (Vol. I., page 316). Some of our readers may remember that a model of this system was on view at Westminster eighteen months ago. The success of this company is due to the energetic spirit of Mr. T. B. Behr, the managing director of the Lartigue Railway Construction Company. The distance between the terminal stations of this railway is ten miles, and the average time of transit is half an hour. The construction has only occupied five months; and this fact, together with its unprecedentedly small cost in proportion to its carrying capacity, makes its erection an event of some importance in connection with Irish railways.

Erratum.—In the reference we made on page 201 of our last week's issue to Mr. J. W. Wells' recent address before the London Chamber of Commerce, the word "Venice" should read "Valparaiso."

The Photographic Exhibition at the Crystal Palace.—In deference to a widely expressed desire, the Directors of the Crystal Palace have arranged for the Exhibition to remain open until the 17th of March, a fortnight later than was at first intended.

The British Association.—A meeting of the members of the Manchester local committee and of the guarantors of the late meeting of the British Association will be held at the Town Hall, Manchester, on the 6th inst., to receive the final report of the local executive committee and the statement of accounts. It will be remembered that the numbers attending the meeting, and the amount received by the Association, were largely in excess of former records. The local expenditure, which will be borne by the guarantors, is considerably below that of the previous year. A call of 35 per cent. was made on the guarantee fund, and the £3,500 from this source, together with the proceeds of minor sources of income, brought the total receipts to £4,369. 10s. The principal items of expenditure included erection of luncheon and retiring rooms, £700; fittings for reception and section rooms, £770; advertising, £240; printing, £470; lodging of secretaries, gratuities, and wages, £570. The receipts from excursions amounted to £716, and the expenditure £711, thus showing a profit where there has formerly been a large deficit.

Notices of Meetings.

THIS WEEK.

Geologists' Association.—Friday, 2nd March, 8 p.m. Papers to be read on "The Pleistocene Land and Freshwater Mollusca from the Barnwell Gravels," by Mr. B. B. Woodward, F.G.S., and on "The Evolution of the Cephalopoda," by Mr. F. A. Bather, B.A., F.G.S.

Royal Institution of Great Britain.—Saturday, 3rd March, 3 p.m. Lecture on "Experimental Optics," by Lord Rayleigh.

NEXT WEEK.

Society of Arts.—Monday, 5th March, 8 p.m. Cantor lecture on "The Modern Microscope," by Mr. John Mayall, jun.—Tuesday, 6th March, 8 p.m. Foreign and Colonial Section. Paper to be read on "South African Gold Fields," by Mr. W. H. Penning, F.G.S.—Wednesday, 7th March, 8 p.m. Ordinary meeting. Paper to be read on "Framework Knitting," by Mr. W. T. Rowlett.

Royal Institution of Great Britain.—Monday, 5th March, 5 p.m. General monthly meeting.—Thursday, 8th March, 3 p.m. Lecture on "Microscopical Work on the Least and Simplest Forms of Life," by the Rev. W. H. Dollinger.

Society of Chemical Industry.—Monday, 5th March, 8 p.m Paper to be read on "The Recovery of Sulphur from Alkali Waste by means of Lime Kiln Gases," by Mr. A. M. Chance.

Royal Institute of British Architects.—Monday, 5th March. Special general meeting. Election of Royal Gold Medallist.

Society of Engineers.—Monday, 5th March, 7-30 p.m. Paper to be read on "The Effect of Sea Water on Portland Cement," by Mr. Henry Faija, M.Inst.C.E.

Institution of Civil Engineers.—Tuesday, 6th March, 8 p.m. Ordinary meeting. Papers to be further discussed: "Manganese in its Application to Metallurgy," "Some Novel Properties of Iron and Manganese," by Mr. R. A. Hadfield, Assoc.M.Inst.C.E. At this meeting the monthly ballot for new members will take place.—Students' meeting. Friday, 9th March, 7-30 p.m. Paper to be read on "The Prevention and Extinction of Fires," by Mr. Alfred Chatterton, B.Sc., Stud.Inst.C.E.

Royal United Service Institution.—Wednesday, 7th March, 3 p.m. Paper to be read on "The Condition of the Mercantile Marine Personelle and Matérial, with a view to its complete utilisation as a Reserve for the Royal Navy," by Captain W. Crutchley.—Friday, 9th March, 3 p.m. Paper to be read on "The Native Army of Madras: its Constitution, Organisation, Equipment, and Interior Economy," by Major-General J. Michael.

Liverpool Engineering Society.—Wednesday, 7th March, 8 p.m. Ordinary meeting. Paper to be read on "Filtration of Sewage," by Mr. J. H. T. Turner, Assoc.M.Inst.C.E.

Society of Telegraph Engineers and Electricians.—Thursday, 8th March, 8 p.m. Paper to be read on "The Present State of Fire Telegraphy," by R. von Fischer Treuenfeld.

PRICES CURRENT, 1st March.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Chili bars have been notably firm during the past week at £78. 10s. to £79 per ton, and a fair business has been done thereat; this is practically an advance of 10s. since our last. The position of manufactured is without alteration.

Tin.—Straits steady at last week's quotations for sharp cash parcels forward delivery according to date, full three months quoted £143 per ton.

Lead is again firmer; Spanish quoted £14. 10s. to £15 per ton. English seems likely to advance still further.

Spelter is very steady at last quotations.

Lancashire and Cheshire Telephone Exchange Company.—The yearly directory, which has just been published, shows that this company is extending its sphere of usefulness. Up to the present time connections have been established between sixty towns in Lancashire, Cheshire, and North Wales, while several towns in Yorkshire may be communicated with by arrangement with the National Telephone Company. The total number of subscribers approaches 5000, and new names are being continually added to the list. Under the system pursued by this company, not only are any two members enabled to converse together, but it is also arranged that outsiders shall be able to communicate with each other by means of public call offices at various parts of each district. The co-operation of the Post Office has been secured in Manchester, Liverpool, and Blackburn, in order that telegrams may be sent to and received from the Telegraph Office through the telephone without the loss of time necessarily occupied by a messenger.

HOME INDUSTRIES.

MANCHESTER, 1st March, 1888.

The Cotton Trade.—The condition of business in cotton yarns is practically unchanged. Spinners have still the advantage of a price which leaves them a margin between cotton and yarn, and are in most cases making a fair profit. This state of things appears likely to last, because, although large quantities of yarn are difficult to sell at present rates, an equal bulk is being sold in smaller lots. The demand for the Eastern markets is undoubtedly very dull, and in almost every case the offers which are made are lower than spinners are disposed to accept. It is now generally admitted that the American cotton crop will be more than 6¾ millions of bales. It is interesting to note that the estimate of Mr. Henry Neill has again proved to be correct, and judging from past experience, this gentleman may be taken as a tolerably safe guide. Manufacturers are finding the competition in cloth much more severe, and there are many well grounded complaints of a scarcity of orders and lower prices in all new contracts. The production of the looms about to be started will exercise a great influence on the future course of the market.

The Bundling of Yarns.—An inquiry is being carried on by the Manchester Chamber of Commerce with the object of ascertaining the legality of certain methods of reeling yarns. Four leading questions have been formulated, and evidence is being taken on the subject. It has been a common practice amongst spinners to reel the yarn into hanks which did not contain the standard 840 yards. In this way yarns have been made into bundles, and sold as being of finer counts than they really were. It is, therefore, a question whether such a practice is not an infringement of the Merchandise Marks Act. It has come out in evidence that the Austrian spinners, who have been reeling in the same way, are now compelled by the Government to mark each bundle the correct count, whatever may be the actual length of the hanks enclosed.

A New Pulley Lubricator.—The trouble experienced by users of loose pulleys, owing to inefficient lubrication, is well known to all engineers. Mr. J. J. Royle, of Manchester, has just begun to manufacture a patented appliance which will be of some service in this direction. Screwed into the boss of the pulley is an oil cup, containing an inner tube, through which the lower end of a brass spindle passes. The upper end of the spindle projects slightly beyond the rim of the pulley, so that every time the belt passes over it, it is depressed. A spring is arranged so as constantly to press the spindle upwards. The tube inside the oil cup is shorter than the internal length of the cup, so that every time the pulley revolves a little oil finds its way into the tube, but is prevented passing out of it by means of a swell at the end of the spindle, which with the lip of the tube forms a valve. When the spindle is depressed the lower orifice is opened, and the upper one closed, the oil thus finding its way into the interior of the pulley boss. The oiling is positively accomplished, and the contrivance is neat and at the same time cheap, and can be easily applied to any pulley.

LONDON, 1st March, 1888.

The Money Market.—The rates for the loan of money have now returned to their normal state, the settlement on the Stock Exchange which began on Monday having hardened the market. The rate of discount still remains low, and shows little sign of strengthening; but for short loans for Stock Exchange purposes the rate was much firmer this week than was the case in the last few settlements. The supply of unemployed capital available for short loan purposes has shrunk so considerably that applications were made to the Bank of England for accommodation. The settlement was a very light one, because the depressed and lifeless condition of the stock markets for a fortnight past has stopped new business altogether. The sensitiveness of the foreign market, due to the unfortunate turn of the Crown Prince's malady, and aided by the effect which the extreme depreciation of the Russian currency has upon Berlin, still adversely affects Stock Exchange business. Substantial investment stocks stand steady; but speculative shares are very flat, though they occasionally experience a fitful revival. The making up prices show a heavy fall during the fortnight in copper shares, and in spite of ever recurring efforts to give them an upward turn, the "bull" movement in copper mines seems almost to be exhausted. So long as the French syndicate is in the field, the shares of the larger copper mines will be the sport of gambling speculators. Investors do well to avoid everything where artificial and abnormal influences are at work to disturb natural market values.

Companies.—The following new companies have been registered since our last report: The Dom Pedro Segundo Gold Exploration Company, Limited (Brazil), with a capital of £100,000; Notting Hill Electric Lighting Company, Limited, with a capital of £100,000; House-to-House Electric Light Supply Company, Limited, with a capital of £35,000; the Halfpenny Letter Post Company, Limited, with a capital of £100,000; the London Produce Clearing House Company, Limited, with a capital of £1,000,000; Clark's Transandine Railway Company, Limited (Chili), with a capital of £1,500,000; the Union Manufacturing Company, Limited, with a capital of £30,000, to carry on a spinning, bleaching, dyeing, printing, and furnishing manufacturing business; the Newfoundland Fish Drying Company, Limited, with a capital of £10,000, to work patents for an improved apparatus for drying codfish, and glutinous, fibrous, and other substances; the Glogan Gold Mines Company, Limited, with a capital of £50,000; the European Pneumatic Tool Company, Limited, with a capital of £60,000, to acquire the patent rights of the pneumatic tool described in *Industries* (Vol. IV., page 157); and the Cornholme Mills Company, Limited, with a capital of £25,000, to manufacture handkerchiefs and other fabrics, in Manchester.

Textiles.—The favourable opening of the colonial wool sales, which commenced on 31st January, and terminated on 25th February, gave promise of good business; but the attendance gradually fell off, and prices, which had advanced from ½d. to 1d., again receded. At the lower rates ruling at the close of the sales, however, there was considerable animation in the market. The next colonial wool sales will commence on April 5th. There is no change in the price of Baltic hemp. In Italian hemp some transactions have taken place, but at lower figures. In Manilla, the tendency of the market is decidedly favourable, and a large amount of business has been done.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 19th February amounted to £1,084,375 on 15,831¼ miles, as compared with £1,090,443 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 122¾ miles, or 0·7 per cent.; and a decrease in the receipts of 0·5 per cent. In order to minimise the number of accidents which occur to porters when engaged in coupling railway carriages, the Great Western Railway Company are introducing the use of a shunting pole.

Compound Locomotives.—Experiments are being made by the London and South-Western Railway Company with compound locomotives. Engine No. 446 has been converted into a compound engine, with cylinders 18in. and 26in. diam., the stroke being 24in. The engine is fitted with one of Mr. Worsdell's starting valves for the admission of high pressure steam to the low pressure cylinder. The valve closes automatically by the action of the exhaust steam from the high pressure cylinder after one revolution of the crank. The steam pressure used is 160lb. per square inch in the boiler.

The Navy.—After the complaints which have been heard from time to time as to the dismissal of workmen from the Government dockyards, it is satisfactory to learn that a number of workmen have been taken on at Chatham dockyard to expedite work in hand. The addition is, however, of a temporary nature, the special work being estimated to last for two months. There have been completed for sea at Chatham, the "Benbow," 10,000 tons, 7500 h.p.; the "Rodney," 9700 tons, 7500 h.p.; the "Warspite," 7390 tons, 5000 h.p.; and the "Hero," 6200 tons, 4500 h.p. The new torpedo depôt ship of 12,000 h.p. which is to be laid down at Portsmouth, is to be called the "Vulcan," and will be considerably larger than the "Hecla."

Our Big Guns.—With reference to Mr. Carbutt's remarks on the bursting of a 10-inch gun at Woolwich, which will be found in our last issue, the Secretary of State for War has stated, in reply to Sir B. Samuelson, that twenty-six 9·2in. breech loading guns, having their liners inside, have been sent to proof, of which twenty-five are being made in the Royal Gun Factory. Of these none of the A tubes have split, as stated, but five have split their liners. He states that this accident is not one of any danger, and many rounds can be fired subsequently without injury to the gun. But the question of these liners is a new one, and is offering to all makers of these guns some unexpected difficulty. No gun ready to be shipped to the Colonies was found to be cracked, still less from end to end; but a crack was found in the hoop over the breech of one gun before the completion of proof.

The Electric Lighting Act, 1882.—Sir Michael Hicks-Beach has stated in the House of Commons that since the passing of the Electric Lighting Act fifty-nine provisional orders and five licenses have been granted to companies, and fifteen provisional orders and two licenses to local authorities. The Board of Trade are not aware of any cases in which the powers obtained are now being exercised.

Progress of New Works.—The extension of the London, Chatham, and Dover Railway from the present terminus at Blackheath Hill to Greenwich, is proceeding vigorously. The contractors, Messrs. Lucas & Aird, have a large force of men employed; most of the cutting is completed, and the masonry is well advanced. Messrs. Appleby Brothers, Limited, the contractors for the landing stages of the Greenwich Ferry Company, Limited, have one of the cylinders on the Greenwich side sunk almost to the full depth, and the excavation ready for pitching the second cylinder.

GLASGOW, 1st March, 1888.

Glasgow International Exhibition.—Notices were issued on Friday last to some of those whose applications for space had been entertained, informing them that their exhibits would be received. It is difficult to estimate the number of exhibitors, since in some of the sections, *e.g.*, the women's industries section, the number is very large. Exclusive of this section, and of the Indian and fine art sections, the number may be roughly estimated at twelve hundred. Upwards of four hundred of these are local exhibitors, while forty come from Edinburgh, eighty-three from London, thirty-two from Manchester, fifteen from Liverpool, and thirty-four from Ireland. The construction of the bishop's palace and of the other outbuildings is rapidly approaching completion, while the machinery section is practically ready for the reception of exhibits. The dynamo room is being fitted with its plant, which consists of twenty-three Brush machines, four of Messrs. King, Brown, & Co.'s machines, and three Thomson-Houston machines.

Ship Owning in Glasgow.—A meeting of the Ship Owners' Association was held last week. Mr. Alexander Allan, chairman, delivered an address upon ship owning, with special reference to the report of the Royal Commission on Loss of Life at Sea. Other speakers complained that freights as a rule were depressed, and attributed this depression to a superabundance of tonnage. The subject of light dues was also discussed. Mr. Browne mentioned that the Clyde ship owners paid a sum of £60,000 a year in light dues, equal to one-fifth of the total sum paid in the country.

Freights.—In spite of the somewhat gloomy tones of the speakers at the ship owners' meeting, the general impression is that freights, especially to the East, are considerably advanced. Quantities of heavy goods which are shipped to the East on speculation are at present being held back, in the hope that freights will fall ere long.

Pig Iron.—The pig iron market continues to be entirely without animation. Stocks are increasing, and though special brands are finding a ready sale, the great accumulation at Connal's stores is sufficient to prevent any but the most temporary advance in price. However, if the American tariff alterations effect a reduction of the duty on iron, the immediate result will not improbably be an upward movement of prices. According to the *Boston Herald*, labour troubles in America are having an influence upon the Scotch iron market there. The coal strike has resulted in shortness of fuel, and consequent scarcity of American iron. The same newspaper alleges that the Scotch-American iron trade is in the hands of a clique, who have temporarily depressed prices in order that they might buy. Should this manœuvre not be unduly prolonged, there may be an impetus given to the Scotch market consequent upon the American double contingency—the probable diverted demand from American to Scotch iron, and the probable tariff alteration. The Tariff Bill is expected to be introduced into the House of Representatives within a few weeks. It is stated that Messrs. Connal & Co., who have had for many years the monopoly of the storage of pig iron, are about to convert their business into a limited liability company. The capital is stated to be £400,000, none of which at present will be offered for public subscription.

Electric Light in City Hall and Bazaar.—The installation of electric light in the City Hall and the Bazaar, which adjoin each other, has been completed. The Thomson-Houston system has been adopted, the work having been carried out by Mr. Richard Miller, Mr. W. A. Bryson superintending on behalf of the Corporation. The plant consists of a Robey horizontal compound non-condensing engine of 50 h.p., two dynamos, twenty-three double arc lamps in the Bazaar, and ten double arc lamps with eight incandescent lamps in the City Hall. The lights underwent preliminary trial on Friday last.

(From our own Correspondents.)

LIVERPOOL, 29th February, 1888.

The Isle of Man Steamship Companies.—The three competing companies for the traffic to the Isle of Man have now issued their financial report of last year's working. While the general public has reaped such enormous benefits from the splendid service of boats, it has been at the expense of the shareholders of the different companies, for each company has been worked at a serious loss. If the three companies are to compete in the coming season, it is to be hoped that terms may be arranged which may be more satisfactory to the shareholders.

The National Steamship Company.—An ordinary general meeting of the shareholders was held last week, to receive and consider the directors' annual report. This stated that there was improvement in the earnings of the steamers, and a reduction in the expense and liabilities of the company. The working account showed a profit of £32,797; the balance of the previous year's insurance account, £94,226, had been written off the capital account for steamers, and an underwriting fund opened. The balance at credit, £16,000, had been invested in British Railway preference securities; the amount of loans on debentures was £52,334, and the depreciation credited with £25,864. The capital had been reduced by paying 25,000 preference shares the sum of £2 per share, which with dividend thereon amounted to £61,314; preferential shares of £10 with £8 paid had been reduced to £8 shares with £5 paid, no other dividend being paid.

The Water Famine.—Notwithstanding the slight recent increase in the amount stored at Rivington, the supply is such as to cause the greatest anxiety, and the Water Committee recently decided to further curtail the already short supply, and during the twenty-four hours there will only be three hours in the morning and three hours in the evening when water can be obtained from the mains. Arrangements have been made with the St. Helens Corporation for an auxiliary supply, on the condition that 4d. per thousand gallons be charged; a new bore hole is to be sunk in the Kirkby well, and new pumping machinery is to be obtained capable of lifting 1,500,000 gallons per day; reports upon the available supply at

Digitized by Google

Abram, Prenton, and Whiston are also to be made. The water at Vyrnwy will commence to be impounded about October. The expenditure on these works for the last three months was, for land and easements, £1,230. 6s. 8d.; Llanwddyn embankment, £17,997; quarry, £5,740; aqueduct, £35,294; making the total net expenditure up to date, £1,697,598.

Liverpool Exhibition Buildings.—The strenuous efforts which have been made from time to time to convert the old exhibition buildings and grounds into a winter garden or other kind of permanent pleasure resort, have proved to be useless, and the council have now placed the whole affair into the hands of a well known firm of Manchester auctioneers for sale, most of the structures, including the Eddystone Lighthouse model, being offered for sale by tender.

SHEFFIELD, 29th February, 1888.

The Heavy Trades.—The competition in all the local heavy trades is very keen; but Sheffield cannot complain of a lack of orders, and its output at the present time is much in excess of that during the prosperous period of 1874. Profits are narrower, and much more work has to be done for less money; nevertheless, with shrewd purchases of raw material, and the adaptability of labour saving machinery to many branches of manufacture, Sheffield firms have not so far been distanced in the industrial race. That some of them are paying less dividends need excite little surprise, for they are the inevitable results of smaller profits. With every probability of the firm prices of iron and steel being maintained, and an undoubted improvement in inquiry for all sorts of heavy material, the current half year should prove a satisfactory one to shareholders in such works. Even the holders of shares in Messrs. Vickers, Son, & Co. (some of whom have been grumbling for days past that the dividend has run down from 14 to 9 per cent.) may find less cause of complaint at the next meeting. The company has recently obtained some capital orders for heavy castings and shipbuilding material, and is busy in nearly all departments. Not much is doing just now in heavy armour plates; but ordinary ship plates, steel sheets, and similar material are in extensive request. A constantly developing trade is also being done in steel for small springs. The engineers are well employed on heavy machinery for various purposes, both on home and foreign account; and work is plentiful at the rolling mills. All descriptions of railway material are inquired for more eagerly, and steel rails have somewhat stiffened in price for best sections. The edge tool manufacturers find trade improving, and some of the old established houses are doing business very largely just now both with the Continent and the Colonies.

Knives.—Most of the cutlery houses are busy, though they find that they have a very narrow margin of profit. Messrs. Joseph Rodgers & Sons (who declared a dividend of 12 per cent. a few days ago) are an exception, for they can practically fix their own price, and scarcely trouble themselves about the competition. The silver and electro-plating trades are doing well.

Coal.—All kinds of coal are in active demand, and the prolonged winter has made prices of household sorts firmer.

NORTH STAFFORDSHIRE, 29th February, 1888.

The Iron Trade.—The outlook is anything but encouraging to makers, and little advance can be obtained over last year's lowest prices, either for pig or finished iron. Forges and mills are with difficulty kept going from four to five turns per week.

Coal and Ironstone.—The severe weather continues, and those collieries producing fuel suitable for domestic consumption are hard pushed to supply the demand. The output is somewhat lessened by reason of the refusal of many men to comply with the provisions of the new Mines Act with regard to the use of safety cartridges for blasting in fiery mines. The demand for ironstone is dull, and prices are low, averaging from 8s. to 8s. 6d. for furnace mine, and 10s. to 10s. 6d. for puddle mine, delivered to local works.

North Staffordshire Mining Institute.—The annual meeting of the members of this Institute was held at Stoke-on-Trent on Monday last. Mr. W. Woodall, M.P., was re-elected president, and Mr. J. Richard Haines secretary. There was an interesting exhibit of mining and mechanical appliances. In his address, the President dealt with the provisions of the Coal Mines' Regulation Act, 1887, having special regard to mining accidents. He pointed with satisfaction to the continually decreasing number of accidents in North Staffordshire mines. Mr. A. R. Sawyer, Government Inspector, mentioned some statistics illustrative of the comparative death rate in England and Germany from mining accidents, which were distinctly favourable to the former country.

North Staffordshire Tramways Company.—The fourteenth ordinary general meeting of the shareholders of this company was held last week, in London. As compared with 1886, the traffic receipts for last year increased by £308, the expenditure amounting only to 58 per cent. of the gross receipts. The Chairman moved that a dividend of 6 per cent. be paid on the preference and 3¾ per cent. on the ordinary shares. A special resolution for the conversion of fully paid up shares into stock was also carried. Since the company started their cars have carried 13,000,000 passengers, and they are now being run with regularity and speed. Having regard to the situation of the Pottery towns, there can be no doubt that this company has supplied a distinct want for some time felt in this district, and the main result of their formation has been to secure an intermediate class of traffic for which the railways were unable to provide.

BARROW-IN-FURNESS, 29th February, 1888.

Iron and Steel.—There is less activity in the hematite pig iron trade, and business has declined even in hematite warrants, although prices are lower; but makers who are tolerably well sold forward have not brought down their prices, and are firm at 43s. 6d. to 44s. per ton net f.o.b. for mixed numbers of Bessemer iron. There is some hope of a revival, because the consumption of iron is increasing, and makers are aware that for many months to come some very large parcels will have to be delivered. There is, however, no doubt of the fact that the production of hematite pig iron throughout the country is too great, even in face of a growing demand; but it is impossible to secure any reduction, except by means of a general understanding amongst makers. There is, however, very great activity in all departments of the steel trade. The inquiry for rails is larger than for some months past, but lower prices are ruling, good heavy sections being obtainable at £3. 18s. 6d. per ton net f.o.b. Plates are quoted at £7 per ton, and angles at £6. 10s., and if makers could deal with orders they would be able to increase their production very considerably. Active efforts are being made to increase the production of all classes of Siemens-Martin steel. There is a satisfactory inquiry for blooms on general American account, and the prices quoted are about £3. 15s. per ton. Billets are also asked for at £3. 18s. 6d. per ton net f.o.b.

Shipbuilding and Engineering.—There is a prospect of some very large orders in shipbuilding coming to Barrow. The order for a large floating dock for Buenos Ayres, to lift a 5000-ton steamer, is all but settled with the Pacific Steam Navigation Company, and orders are expected for some large ocean steamers, as well as for Nordenfelt submarine torpedo boats. In engineering and boiler making there is a better feeling, and there is a more cheerful tone throughout the town and district than has been experienced for some months past.

MIDDLESBROUGH, 29th February, 1888.

Pig Iron.—There is every reason for an improvement in the pig iron market, but there is none. This is caused mainly by the market being in the hands of merchants and speculators, whose interest it is to keep it down. There are sellers at 31s. 6d., but buyers offer 3d. less. There is really very little business being done at all. In the meantime stocks are declining, and many makers are waiting to see what the monthly returns will be.

Exports of Pig Iron.—This month's exports are highly favourable, having, up to the 27th, amounted to 60,175 tons, as against 55,830 tons to the 27th of last month, and 50,070 tons to the 27th of February last year. The latter part of the month has been very stormy, else more would have been exported. It is satisfactory to know that the exports are increasing in every direction, with the exception of America. Germany and Holland have taken nearly twice as much as during the same period last year. The coastwise shipments also have materially increased.

Finished Iron and Steel.—Both of these are much as they were last week. Finished iron is firmer perhaps, but it does not take so much to make this trade busy now-a-days. Steel rails are quiet, but ship plates are in very strong demand. The rising price in ship plates is likely to be checked by the unexpected appearance of German plates. These, however, can only be temporary rivals. The increasing plant in preparation to overtake the increasing demand should make competition of that sort impossible.

Engineering.—The boiler yards are fairly busy on going orders, chiefly for foreign destination. Marine engineering is exceptionally busy, on account of the rapid improvement in shipbuilding. In the manufacture of railway plant there is as great a turnout as ever.

SUNDERLAND, 29th February, 1888.

Shipbuilding.—Owing to the difficulty of obtaining delivery of steel plates and angles, several shipbuilders are, with the consent of their customers, fitting iron in place of steel for floors, engine and boiler seatings, bulkheads, &c. A few days ago the Chief Surveyor visited Sunderland and held a conference with the local shipbuilders. He submitted draft copies of the proposed new rules for steel vessels.

Shipping.—The monthly trade return for January, laid before to-day's meeting of the River Wear Commissioners, shows that 552 vessels of 206,287 tons register, paying dues to the amount of £1,798. 16s. 5d., cleared from the port, being an increase of twelve vessels, 2660 register tons, and £35. 0s. 4d. dues, as compared with January, 1887. The total quantity of coal shipped was 336,331 tons, an increase of 3269 tons over the corresponding period of last year. The entire revenue of the Commission for the last month was £10,167. 6s. 2d., as compared with £9,227. 0s. 3d. in January, 1887, an increase of £940. 5s. 11d.

The Coal Trade.—There is no steady rising tendency in the price of coals. Merchants affirm that if the shipments are to be maintained, lower rates will have to be accepted. This statement appears to be borne out by recent statistics. The coal shipments at this port amount to 73,974 tons, of which 23,849 were sent abroad, and 50,125 to ports in the United Kingdom. In the previous week the total only reached 67,487 tons; in the corresponding week in 1887 the shipments were 82,867 tons.

Boat Building.—Wearside boat builders are on the whole well employed. Messrs. M. Robson & Son have just received an order from Palmers' Shipbuilding and Iron Company, Limited, for an outfit of boats for an unusually large passenger steamer. All the boats are to be built of teak, and six of them are also lifeboats.

Boat Lowering Apparatus.—Mr. Wm. Mills, of Southwick, to whom was awarded a silver medal at the Royal Jubilee Exhibition, Newcastle-on-Tyne, for his boat lowering and disengaging apparatus, has just obtained a large number of orders for the gear, and his works are kept busily employed.

Cement Works.—The cement manufacturers have their works actively employed. Orders appear to have been equally divided between the Sunderland Cement Company, Limited; the Wreath Quay Cement Works Company, Limited; the Hylton Cement Company; and the Deptford Cement Works.

NEWCASTLE, 29th February, 1888.

Iron.—The improved condition of the finished iron trade, which was noted in previous reports, is still maintained, the works being generally busier than they were at this time last year. The output of Messrs. Raine and Co.'s works, Winlaton, since the opening of the year, has exceeded, by many hundred tons, the production for the corresponding period in any former year. Other manufactories, though not showing such extremely satisfactory results, have in every instance turned out a much larger quantity of material than they have been in the habit of doing for some years past. Manufacturers still hold firmly to the advanced prices obtained in December last, though with reference to some descriptions of the commodity considerable pressure is being brought to bear upon them for easier terms. A very strong reason for refusing concession in this direction is that before the advances referred to were obtained, the margin of profit was so small as to be often almost non-existent, and it will go hard with manufacturers before they again consent to do business on so unsatisfactory a basis.

Steel.—The output of product at the Consett steel works steadily increases each week, as the newly added productive resources are being brought into requisition. The other extensions of works in the district are being actively proceeded with, and it is expected that in a short time the supply of steel plates, angles, &c., will equal the demand. All departments of the Newburn steel works are now extremely busy, and the steel factory in connection with Sir W. G. Armstrong, Mitchell, & Co.'s Works, Elswick, is among the most briskly employed departments in that great establishment. Iron and steel sheets have been exported this year in large quantities by the Redheugh Iron and Steel Sheet Company, among other shipments being one of 600 tons to Kurrachee.

Chain and Anchor Works.—Both the chain and anchor departments at Messrs. Abbot's establishment, Gateshead, are now tolerably busy, some orders for large anchors having recently been received. At Messrs. Hawks, Crawshay, & Co.'s works there are also some very heavy anchors of a special type in course of manufacture.

Re-opening of a Shipyard.—Arrangements are now being made for the immediate re-opening of Messrs. Palmer & Co.'s Howdon yard, which has been closed since 1884. This step is understood to have been made necessary by the fact that this firm have contracted for a very large amount of work, a considerable portion of which has to be turned out by the end of the year.

DUNDEE, 29th February, 1888.

Flax and Jute Trades.—There has been a lack of animation in the staple industries of the town during the past fortnight. Notices have been put up in most of the jute works, that for three months machinery will be stopped on Saturdays. The flax market has been somewhat irregular. The sudden fall in the Russian exchange has made sellers more anxious to offer, and considerable sales are reported at low rates. Flax and tow yarns meet with a slow sale, which is partly accounted for by the fall in the price of flax. Manufacturers are willing to operate on easier terms; but prices are difficult to arrange, as spinners still hold out fairly well. There is no improvement in the demand for linen goods; but for fine fabrics, more especially those produced in the Fife district, the orders on hand are sufficient to keep the factories well employed. Jute has been selling freely, and prices are firmly maintained. Jute yarns continue in fair request, but the advanced rates asked act as a check upon business. In jute goods Hessians are in moderate demand and prices fully maintained, but there is an absence of forward buying. The probability of an alteration in the American tariff is a good deal canvassed by the trade. It is feared that should Congress take off the duty on raw jute, and retain the heavy duties on manufactured goods, Dundee would be exposed to serious competition from American producers. Sacking and bagging continue in active request at late rates.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

FRIDAY, 2ND MARCH, 1888.

THE ASSOCIATED CHAMBERS OF COMMERCE.

THE annual meeting of the Associated Chambers of Commerce was held last week, in London, when delegates from the provincial Chambers met to discuss matters of current commercial interest. Though a good deal of solid information and a considerable mass of statistics were contained in the speeches of the President, Sir Bernhard Samuelson, M.P., of Sir Jacob Behrens, Sir John Lubbock, and the other commercial and financial magnates who took part in the discussions, there was an absence of matter for exciting discussion. The old stories of the desirability of arbitration between nations—not between business firms—instead of war, fair trade, and the need of national harbours of refuge, were debated and resolved upon, and more strictly commercial questions, such as commercial education, railway rates, and the amendment of the Joint Stock Acts, were discussed at some length. In all there were sixty resolutions on the agenda paper. The report of the Executive Council, reviewing the commercial history of the last Parliamentary session, concluded with certain recommendations. These were that the system of devolution of public business to Committees of the House of Commons be extended, and that to these Committees—which should be fairly representative—all Bills not involving questions of Imperial policy should be relegated. The report also recommended the carrying forward of measures not completed in one session to the next session, and it also suggested that the power of blocking Bills should be restrained. While all these measures are obviously sensible, a preliminary question might be raised. Why should Parliament have so much to do? Why should our legislative machine be worked so hard that the old means of lubrication are no longer sufficient? Last session seventy-four Bills were passed through Parliament, many of them measures that will have to be amended in the course of a year or two, and a few of them measures that nobody wanted except it be the few crotcheteers who manœuvred them through the Houses of Parliament. If, however, so great and important additions must annually be made to the statute book, it is essential that they should be made with as full knowledge of the needs of each special case as is possible. Committees to whom non-partisan measures might be referred form a useful invention of which much more extended application might be made. There is another mode of securing the passing of Bills efficient for the purpose intended, which seems likely to be adopted to a considerable extent in the future. That is the appointment of a board or committee of skilled persons in special departments to act along with the Government departments in preparing legislation and in administering the law. The Board of Agriculture and the proposed Committee in the Boiler Registry and Inspection Bill are instances of this kind. The members of such Committees are not necessarily members of Parliament; they are selected from among men who have distinguished themselves in special departments, and who are, therefore, looked upon with certain confidence by the public. This might well form the text of a future resolution at a meeting of the Associated Chambers. The suggestion that the "massacre of the innocents" should be abolished, and that Bills which have passed through the preliminary stages should, on the reassembling of Parliament, be taken up at the stage at which they were dropped, is an eminently reasonable suggestion. There is really no valid constitutional reason for the waste of time involved by thus summarily disposing of measures upon which time has not been found for complete discussion. That change of conditions involved in a dissolution does not occur when Parliament is simply prorogued. It is to be hoped that some Government will ere long have the courage to propose such obvious improvement in the conduct of public business as the Associated Chambers have suggested. The power of blocking Bills would be deprived of a large part of its efficacy if Bills were carried over, since part of the delightful experience of "blocking" is the knowledge that, if successfully postponed till the end of the session, the Bill is almost sure to be found among the "innocents." The address of the President, Sir Bernhard Samuelson, referred mainly to the improvement of trade which he said had taken place during the last six months of 1887 and the early weeks of 1888. He quoted the figures of our total cargo trade for 1887, showing that our foreign trade amounted to 56,000,000 tons, an increase of 2,370,000 tons over 1886. Adding the coasting trade of 27,500,000 tons to our foreign trade, made a total of 83,500,000 tons shipped from our ports. And adding to this the 270,000,000 tons carried on our railways, an estimate is possible, though necessarily not very exact, which would place our aggregate of transported goods at 353,500,000 tons. This, of course, is not the total of our production, for a great quantity of raw material is productively consumed almost or altogether *in situ*, or is transported by more primitive means than the railway or the steamboat. Sir Bernhard also drew attention to the circumstance that recent increases in foreign tariffs in the United States and in Italy had increased the cost of living everywhere abroad. Against this bare statement may, however, be placed the arguments that the remuneration of labour, in the United States at any rate, is rather higher than it is in this country, and that wages in proportion to the standard of comfort are probably rather higher and more uniform in protected countries than in free trade countries. This, however, must be taken with due reservation, for absolute statements are to be avoided on both sides. It is extremely difficult to compare the wages and prices of two different nations working under different climatic conditions, and with different standards of comfort. Statements as to the increase of the cost of living in protected countries can therefore only be accepted in very general terms, and as operating over comparatively small areas. Sir Bernhard also referred to the Paris Exhibition, and to the subject of commercial education. This topic formed the basis of a resolution moved by Sir John Lubbock, to the effect that it is desirable to obtain an alteration in the School, Civil Service, and University Examinations, to substitute modern languages and elementary science for the classical subjects in these examinations, and also suggesting the appointment of a Minister of Education, and the insertion of clauses in the Technical Instruction Bill, which will doubtless be revived this session, to provide for teaching commercial subjects and modern languages in technical or board schools. A resolution presented by a number of provincial Chambers also dealt with technical education, and urged that evening as well as day schools should be

Digitized by Google

provided, and that proper provision should be made for the systematic training of teachers. This resolution also suggested that grants should be given for proficiency in technical and commercal education, and that the clause in the Bill of last year, which made its adoption permissive, should be cancelled so far as the ratepayers are concerned, and that powers should be given to the local authorities to adopt the Bill without appeal to the ratepayers. These are all important suggestions; but the main point upon which none of them indicated any opinion is, what do they mean by technical education. Commercial education is not quite so ambiguous, but many persons seem to have a very hazy opinion as to what they really want when they demand technical education. We have from time to time in these columns pointed out some of the lines upon which we think technical education ought to be administered; but it would be well if public bodies, instead of passing general and vague resolutions like those quoted, condescended somewhat more to detail, and described to us whether they want handicrafts taught in schools, or whether they mean by technical education that training in principles which every man who works with his hands ought to have in his head. The question as to whether the ratepayers ought to be disregarded, except when called upon to pay the rates, is too important for slight treatment. The experience of the Libraries Act is perhaps the moving cause for such a proposal. It has been extremely difficult to persuade the ratepayers of the large towns to adopt the Act and pay the tax; and the presumption is that technical education might be similarly delayed. It is, however, an unsafe method. The practice of directly appealing wherever possible to the persons who are to defray the cost, is too sound to be disturbed without substantial reason. The system of payment by results or grant-earning must clearly undergo considerable modification before it is extended. While there is some sound reason why the nation as a whole should share in the cost of what is a benefit to the nation as a whole, it is by no means to be assumed that a pecuniary grant per student passed is the best method of securing this. The system has been discredited in elementary education, and it has unquestionably worked some mischief in science education. To make it otherwise than injurious to efficient teaching, and absolutely fatal to cramming, it would be necessary to re-construct the system root and branch.

ELECTRIC STREET LIGHTING.

The recent action, or, rather, want of action, on the part of the City authorities, to which we drew attention in our last issue, is calculated to bring the subject of street lighting more prominently before electrical engineers and contractors. The lighting of our streets is a question which has been rather neglected during the last few years, and improvement in lighting plant has mainly been made with a view to its use in private establishments. This, we cannot help thinking, is a mistake, as engendering on the part of those responsible for civic improvements a feeling of hesitation. If the problem be to light a large hall, a factory, a schoolroom, or offices, the opinion of experts and outsiders would scarcely differ about the best method to be adopted in each case; but as soon as the question arises of how to light a public thoroughfare, opinions become divided. We do not mean to say that the opinion of electric light engineers, who thoroughly know their business and mean to do good work, would differ; but their opinion is easily over-ruled by that of outsiders, who cannot possibly discriminate between one system and another in its adaptability for a special purpose. This was strikingly shown at the meeting of the City Commissioners of Sewers, on the 22nd ultimo, when a substantial and workable scheme brought forward by the Brush Corporation, and which had obtained the approval of the Streets Committee, was shelved because of two rival schemes, which we cannot characterise otherwise than as absurd, but which, notwithstanding their defects, palpable to engineers, at once obtained the support of a large number among the Commissioners. One of these schemes was to replace the gas jets in each street lamp by three glow lamps. We should be very sorry to see such a proposal carried out, because it could only discredit electric lighting. Many years ago, Pentonville Road was lighted by glow lamps, and the result was a complete failure, as was also the lighting of Holborn Viaduct, which was carried out in the same manner. The light given by a glow lamp is more or less of the same character and power as a good gas jet, and it is inferior to the Siemens, Wenham, or other regenerative burners now in the market. The reason that glow lamps are adopted indoors is not on account of giving more light than gas, but because of the greater convenience, cleanliness, and the absence of any products of combustion. These advantages are sufficiently great to counterbalance the larger cost as compared with gas, but in the streets these advantages become illusory. Where the products of combustion escape directly into the atmosphere, non-pollution of air and cleanliness become immaterial, whilst the question of convenience is reduced to the small matter of dispensing with the lighting and extinguishing of each lamp; but even this could in the case of gas be done automatically by a pilot light and regulating apparatus which is called into play by a sudden rise or drop in the gas pressure. The glow lamp (Parson's high candle power glow lamp perhaps excepted), therefore, possesses no advantage whatever over the gas jet, whilst the cost of lighting must always be greater. Electricity is now sold by one large company in London at the rate of 7½d. per Board of Trade unit. This is a very low figure; but assuming even that the supply could be obtained at 6½d. for municipal purposes, the cost of incandescent lighting would still be about twice that of gas. We may therefore dismiss the proposal to light the streets by glow lamps as too absurd for further consideration.

The other rival scheme which helped to shelve the report of the committee, was that put forward by the Maxim-Weston Company, and on close inspection it will be seen that this is hardly less absurd than the other. This company offered to erect a central station generating plant, and eight hundred small arcs throughout the city, for the modest sum of £15,000, and to work the plant for an annual charge of £3,875. The lamps were to be 450 n.c.p., and to be kept alight from sunset to sunrise, that is, roughly speaking, for 4300 hours per annum. The lamps are presumably the Watt lamps, about which a great deal has been written in the daily press, and nothing at all has transpired in the scientific journals. To judge by the reticence observed both in the matter of the dynamo and the lamp, the inventor seems to prefer the verdict of the non-scientific newspaper reporter to that of a skilled electrician when he submits his invention for inspection. We have, therefore, no means of knowing anything about the merits or otherwise of the Watt lamp: but assuming this small lamp to be as efficient as an ordinary 10 ampère lamp—an assumption which is by far too favourable—each lamp would require 225 volt-ampères; and allowing a loss of 25 volt-ampères for the leads and regulating devices, we find that each kilo.-watt generated at the station would maintain four of these lamps alight. For the eight hundred lamps, the total capacity of the generating station would have to be about 200 kilo.-watts, and the yearly output 860,000 Board of Trade units, which, calculated at the low figure of 6½d., represents a charge for current alone of £2,325, to say nothing of the cost of carbons, which will probably amount to one-fifth of a penny per hour per lamp, representing an additional outlay of £2,800 per annum. This does not include the cost for trimming lamps nor outdoor supervision, which must necessarily be high where a large number of small lamps is employed. From our figures it is obvious that the Maxim-Weston Company must have made some mistake or other in estimating the annual working expenses, which they will find out to their cost, and perhaps to that of the City also, if they obtain the contract on these lines. It is obviously not to the advantage of any community to get contractors to work for them at a loss, for in such cases the public is certain to be badly served. We may therefore also dismiss the Maxim-Weston proposal as impracticable on account of economic reasons, and the question remains whether arc lighting in any shape or form would be an improvement upon the present system of gas lighting.

When a part of the City was lighted by arc lamps for the first time, the service was not altogether satisfactory: the light flickered a good deal, and the lamps were fixed on posts so low as to inconvenience the drivers of omnibuses and vans. Since then great improvements have been made in dynamos and lamps, and those of our readers who saw the Manchester Exhibition must have noticed how exceedingly steady was the light of the Brush arc lamps—the number of lamps which were there in nightly use being far in excess of that now proposed for the City. It is therefore reasonable to expect that the company would find no difficulty in supplying an equally good light in the City, and as the lamps would be fixed on posts 18ft. high, no inconvenience to drivers of high vehicles would ensue. The annual cost of running a 10 ampère arc lamp from sunset to sunrise is variously computed in this country at from £25 to £35. The Thomson-Houston Company, in the United States, supply a lamp according to its position and the competition encountered from other electric lighting companies, at a charge varying from £20 to £10. Now, the Brush Company offer to run their lamps at a charge of £26 each, and it will thus be seen that their offer is not so low as to make a loss inevitable; at the same time it is sufficiently low to be advantageous to the City, which would thus have to pay only twice the price of gas, and obtain about thirty times the light. The reason why, under the Brush scheme, the City can be efficiently lighted at a moderate outlay, must solely be sought in the employment of lamps of fairly large candle power. It is well known that large arc lamps give more light per unit of energy expended than small ones, whereas the cost of carbons and attendance is not materially affected by the size of the lamp between the limits of say 500 to 2000 c.p. It is thus obviously of advantage to employ a smaller number of high candle power lamps in preference to a large number of small candle power lamps, and to place them on posts considerably higher than gas lamps are fixed. The system elaborated by the Brush Corporation appears to us the proper solution of the problem how to light our streets electrically, and if carried out it will probably form the pattern for similar work in other parts of the Metropolis.

CENTRAL STATION LIGHTING BY STORAGE BATTERIES.

At the last meeting of the Society of Telegraph Engineers and Electricians, this system of distributing electricity was warmly advocated by Mr. Gordon and Mr. Crompton, the latter gentleman speaking from personal experience in the use of storage batteries for this purpose. As this is a question of great importance to electrical engineers and contractors, it will be of interest to our readers if we give a short account of a visit we recently paid to Mr. Crompton's central station at Kensington Court, to inspect the machinery and distributing plant. Since we published an illustrated description of this station in our issue of the 18th February, 1887, the plant has been duplicated. There are now installed two boilers and two direct acting steam dynamos of the Willans-Crompton type. One of the dynamos is a double horseshoe horizontal machine, and the other is of the inverted single horseshoe type. Each machine is able to supply current equal to from 40 to 45 h.p., but only one machine is at present required at a time. At one end of the machine room there are stages for several batteries of storage cells; but only one battery is at present in use, and is connected by means of an ingenious switch board with three lighting circuits, all of which have a very low resistance, so that the loss of pressure in the mains is only trifling. At present the routine of the installation is as follows: One of the engines is started about three o'clock in the afternoon, and begins charging the battery. At the same time the current is sent out from the battery to the various lighting circuits, and these connections are never interrupted during the whole twenty-four hours, so that consumers can have the light at any moment of the day or night. The consumption reaches a maximum towards seven o'clock in the evening, and by about eleven o'clock it has again sufficiently declined to allow of the engine being stopped. Meanwhile the batteries have received a sufficient charge to last till the next afternoon. After stopping the engine at eleven o'clock, the station is locked up and left to itself. The charging current and the discharging current are both measured by Aaron's coulomb meters, and in the consumers' houses there are installed either Ferranti or Cauderay meters. The mains in the streets are of a novel construction, and consist of bare copper strips supported on porcelain insulators within a brick culvert set in cement. At certain intervals a flag of the footpath is provided with lifting rings, so that it may be lifted to give access to the mains. The house connections are simply soldered on to the copper strips, the switch and fuse being placed, not in the culvert, but at the entrance to the consumer's premises. Each main is protected by fuses at the station, and potential wires are carried back from the far end of the main to the station, to indicate the pressure at the lamps. The attendant is therefore enabled to regulate, by means of the switch board already mentioned, the number of cells working on any particular circuit, so as to maintain the pressure constant within one or two volts.

PATENT LAW.

In concluding our review of patent litigation for the year 1887, in our issue of the 20th January last, we ventured to state a proposition, which we thought would appeal to common sense, viz., that commercial success was a fair test of novelty and of patentability. We scarcely anticipated having judicial decision to support this, but the proposition has since been made good in two cases. The first case was the decision of the

Digitized by Google

Court of Appeal in an action brought by the American Braided Wire Company against Thompson. The American company were the owners of Letters Patent, dated 25th July, 1885, for "Improvements in bustles or dress improvers." The bustles were made of tubular braided wire, and very large quantities of them had been sold. The action came on before Mr. Justice Kekewich in July last, and he declared the patent invalid. He held that the "plaintiff's invention was merely the application of material of a previous patentee to purposes *analogous* to those pointed out in the specification." On appeal, the case came before the Lord Chief Justice and Lord Justices Cotton and Bowen. The Court of Appeal upheld the validity of the patent, and the following will show what influenced them in arriving at this result. Lord Justice Cotton remarked, "There was the circumstance that a large sale at once followed the introduction to the public of bustles made according to the specification." Lord Justice Bowen, in giving judgment, asks this question, "Unless there is some ingenuity in the person who brought out this article, why was it never brought out before?"

The second case to which we have referred was Ehrlich *v.* Ihlee and Sankey, in which judgment was delivered on the 21st ult. The plaintiff was the inventor of a musical wind instrument known as the "ariston." The valves are opened by levers which were operated by means of slots in a circular disc. Since the date of his patent, in 1882, the patentee had sold over 150,000 of these instruments, and over 2,000,000 of the discs, or musical sheets. Mr. Justice Kekewich decided in favour of the patentee. In giving judgment he referred to the case of the American Braided Wire Company *v.* Thompson in these words: "I conceive the following proposition to be established by that case. If, within a short time of the first manufacture and sale, an article of commerce commands a ready and extensive sale, that fact, which is proof of utility, must also be accepted as evidence, not conclusive, but cogent, of novelty. The words are mine, but the substance underlies the judgment of certainly two of the members of the Court in the particular case, and particularly that of Lord Justice Bowen, who asked the very question which I asked myself in Siddell *v.* Vickers: 'Unless there is some ingenuity in the person who brought out this article, why was it never brought out before?' The proposition commends itself to one's common sense, if I may venture to say so; and it is the more applicable here because the introduction of the ariston displaced other instruments which, until then, had been largely sold by the plaintiff, and which, according to the evidence, not only have not been sold, but cannot be sold now."

Letters to the Editor.

THE BOARD OF TRADE INSPECTORS AND VERTICAL FIRE BOX BOILERS.

To the Editor of "Industries."

Sir,—The thanks of the steam using public, as well as those of engineers and boiler makers, are undoubtedly due to your correspondent "Economiser" for drawing such pointed and timely attention to the question of the strength of short flues, furnaces, or fire boxes of vertical boilers, and it is to be hoped that boiler makers who make the manufacture of such boilers a specialty, will adopt "Economiser's" suggestion, and forward to you the result of their experience of the behaviour of fire boxes under hydraulic pressure. It would form interesting, instructive, and valuable data, and would also supply important evidence as to the reliability or otherwise of this type of boiler.

The boiler described by Mr. Peter Samson in his Report No. 145, is stated to be of the ordinary wrought iron vertical type, with two cross tubes in the fire box and a vertical uptake; the outer shell 4ft. diam. and 7ft. 4in. high, made of four plates arranged vertically, the seams lapped and double riveted with ¾in. rivets, 2in. pitch. The crown of shell was in one plate, dished, flanged, and single riveted to shell. The fire box was slightly conical, about 4ft. high, exclusive of the crown, 38¼in. at the top and 40¾in. at the bottom, internal diameter, with plates arranged vertically, lap jointed and single riveted. The crown was made in one plate, dished, flanged, and single riveted. There were two 8in. welded and flanged cross tubes in the fire box, fixed at right angles to each other. The uptake was 12¼in. at the top, and 10⅜in. at the bottom, secured by angle rings to shell and fire box. According to the Board of Trade instructions to surveyors, the collapsing pressure of the fire box of such a boiler would be, as shown by Mr. Samson, 141lb., and by the same instructions the proper safe working load upon the safety valve should not exceed 28·6lb. Now, by the usual formula adopted by engineers, the collapsing pressure would appear to be about 600lb. per square inch, consequently the fire box ought to prove stronger than the shell in this instance, the bursting pressure of which would be about 500lb. per square inch.

If a boiler were made to the sketch accompanying "Economiser's" letter and to the dimensions given above, and it was proposed to a boiler insurance company, it would be accepted without demur; for a daily working pressure of 141lb.—the load which, according to Messrs. Traill and Samson, or the Board of Trade instructions to surveyors, would at once collapse the fire box. Either Messrs. Samson and Traill are the authors of another ridiculous scare, and the finders of another mare's nest as huge as that discovered by Mr. W. Woodthorpe of the "so-called economisers," or the engineering practice of the United Kingdom is hopelessly blundering on in the dark. If boiler makers respond to "Economiser's" invitation, this question may be shortly decided, and in the interest of the public generally it is of the utmost importance that it should be. Should there be anything like 25,000 of such boilers in use in Great Britain, the urgency of the matter can scarcely be exaggerated, when such a vast disparity exists between the engineering opinion of the country and that of the Board of Trade inspectors, which might at any moment result disastrously both with regard to property and life. It is perhaps, however, unnecessary to take too serious a view of Messrs. Traill and Samson's Report (No. 145) and its conclusions, and we—speaking for steam users generally—shall possibly run into no danger by treating it with disrespect.

Some other of the Board of Trade inspectors do not attribute all cases of collapse to want of compliance with the Board of Trade instructions to surveyors, and they have theories and explanations which, though probably of no more real weight or value than the one just referred to, still have a merit of their own, certainly of ingenuous simplicity. To prove this assertion, let me take the evidence of Mr. G. Carlisle, another of the Board of Trade inspectors. On the 28th April, 1883 (see Report No. 29), he reported upon the explosion of a boiler at the Huyton Iron Works, Huyton Quarry, Lancashire. The boiler was of the Lancashire type. It had two furnaces, each running into a through flue of the same diameter, fitted with Galloway tubes, placed diagonally. The boiler was 30ft. long, 7ft. diam., made of $\frac{7}{16}$in. plates, lap jointed, double riveted longitudinally, and single riveted circularly. "The furnaces and flues were composed of ten lengths, the end lengths being conical. The furnaces comprise the first three lengths at the front end of the boiler, and were of $\frac{5}{8}$in. plates, lapped and single riveted, both circumferentially and longitudinally. The flues comprise the remaining seven lengths, and were of $\frac{7}{16}$in. plates, the longitudinal joints being butted and fitted with outside straps single riveted. The circumferential joints were made by single riveting the edges of the rings of plates to the flanges of T iron hoops, spaced about 3ft. apart. In each flue there were three diagonally placed Galloway tubes, about 10in. diam. at the upper end."

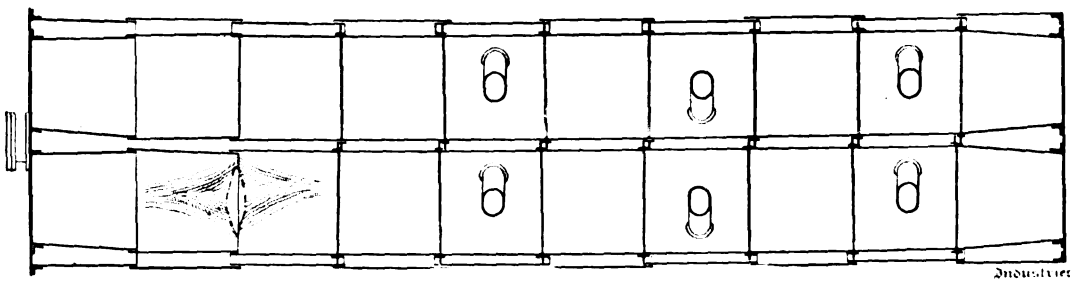
This explosion, says Mr. G. Carlisle, was due to the collapse and rupture of the crown of the right hand furnace. The water and steam escaping through the rupture bared the top of the left hand furnace, in which there was a good fire, and this caused the over-heating of the top of the left hand furnace; but it was not distorted or materially injured. Mr. G. Carlisle then goes on to state that, "*in my opinion, this explosion was due to the excessive strain thrown on the seams, and the flattening tendency of the top of the furnace caused by the sudden contraction of the top of the furnace and flue in consequence of the furnace door being open for a period of from five to ten minutes whilst the furnace was being cleaned, the dampers being open at the same time.* Similar contractions on previous occasions may possibly have caused cracks between the rivet holes, and the loosening of the rivets of the circumferential seams, which I observed existed, and which have been of frequent occurrence hitherto in this boiler."

In Mr. Carlisle's further remarks upon this case, he states that "during the clearing of the fire, a current of cold air would be impinging against the top of the furnace and passing along the flue to the chimney. A slight fizz at the circumferential seam immediately over the fire was observed at the time, but as it had been seen on previous occasions no particular notice was taken of it. . . . The engineman had just been round the boiler to see that all was right, and both he and the fireman swear that there was plenty of water in the boiler, and that the steam gauge showed 50lb. . . . From the foregoing particulars, and the attached sketch, it will be seen that the flues are very much stronger than the furnaces, both as regards plating and method of construction. It therefore seems to me that the variations of length of flue and furnace, due to the expansion and contraction of its 30ft. length, would tell very severely on the weakest ring or rings of plates, and would be quite sufficient to account for the trouble hitherto experienced with these furnaces. The impact of a volume of cold air with the heated plates of the top of the furnace would make them contract, and tend to flatten and otherwise distort them. The ultimate strength of this furnace, had it been perfectly cylindrical and cold, by Fairbairn's formula, is about 100lb. The collapse, therefore, of this lapped and single riveted furnace—distorted and, possibly, partially fractured—at 50lb., is only what might have been expected."

If Mr. Carlisle's calculation by "Fairbairn's formula" is correct, and the collapsing pressure of the furnace was only "about 100lb.," as he alleges it to have been, this boiler must have been working, according to the information given in Report No. 29, night and day (except when being cleaned) about two years, with a factor of safety of only 1·4. In Report No. 145 Mr. P. Samson and Mr. T. W. Traill, Engineer Surveyor-in-Chief, unite in deciding that a fire box with a factor of safety of 2·16 (by their own calculation) collapses and explodes because "the pressure at which the boiler was worked was too great for the thickness of plates in fire box." Yet Mr. Carlisle makes no remark upon this furnace with a factor of only 1·4, and attributes the collapse to "the sudden contraction" of the top of the furnace and flue, in consequence of the furnace door being open for a period of five to ten minutes, whilst the "furnace was being cleaned, the dampers being open at the same time."

It will be observed that no "observations" by the Surveyor-in-Chief (to borrow "Economiser's" humorous expression) are appended to Report No. 29, this, no doubt, being due to the very awkward conclusion to which his subordinate had led him, viz., that furnace doors should not be kept open while cleaning, otherwise furnaces would collapse from sudden contraction caused by the impact of a volume of cold air upon the heated plates. The Engineer Surveyor-in-Chief would no doubt fully appreciate the dilemma into which he was thrown, as he could scarcely "observe" that furnace doors should be kept closed during cleaning, there being some physical difficulty in carrying out such an instruction, apparent even to an official mind. Had the deductions of this Report, however, been carefully scanned, matter would have been found by an expert for some interesting "observations" of an *unofficial* character.

The simple precaution of checking Mr. Carlisle's calculation by "Fairbairn's formula" would have shown that the collapsing pressure of the furnace by that formula would be about 300lb., assuming it to be 3ft. diam., as it appears by proportion from the sketch. The calculation that Mr. Carlisle has made appears to have been by the Board of Trade formula for "surveyors," which (taking the furnace to be 3ft. diam.) would be, as he states, about 100lb. It might then have been prudent also to inquire what are the general habits of furnaces of the same character, and if it is customary for them to collapse during the time fires are being cleaned; and it would have been well to have found one case, even of a collapse of a furnace, that has ever taken place due to such a cause. Failing to obtain a satisfactory reply to these inquiries, some thought might have been given to the question: Do fire boxes or furnaces ever give way that are not weak in themselves, and at the same time amply supplied with water? It is the habit of the Board of Trade inspectors to take so much evidence and to collect so many opinions, that it might be thought after eighteen days' cogitation a less curious conclusion would have been arrived at in this case, than that keeping the fire door open from five to ten minutes during the cleansing of the fires, even with an open damper, should have caused the explosion.



As no competent engineer will endorse this opinion, the question arises, did the furnace collapse from weakness? If, as Mr. Carlisle states, the collapsing pressure was only 100lb., with a factor of safety of 1·4, why did the second furnace not collapse, and why did the injured furnace work safely for more than two years night and day, at 70lb. pressure? If, again, the collapsing pressure of these furnaces was about 300lb., as they would be if really calculated by Fairbairn's formula, why did one of the furnaces collapse, providing that the boiler had a sufficient supply of water, which Mr. Carlisle does not appear to question? Such a report as the one now under consideration should never have been published, in the interests of the Board of Trade inspectors; but as evidence as to the value of their opinions and supervision, it appears conclusive. The great object of the official mind is to throw off and avoid responsibility. The engineering practice of this country says a factor of safety of 4 is sufficient, the whole of the boiler insurance companies and the Manchester Steam Users' Association are satisfied with a factor of 3, but the Board of Trade instructions to surveyors state that 5 must be the factor.

In other words, let there be no responsibility; make the factor sufficient; if 3 will do, and 4 is perfectly satisfactory, by making it 5 there can be no doubt, and consequently no responsibility. Let the steam using public be thankful that we do not make the factor of safety 6 or 7! Where would the great engineers, who have made the wealth and prosperity of this nation, have been had they been subjected to the cast iron rules of a Board of Trade? And let me ask, in conclusion, will engineering progress of the future keep pace with that of the past, or the present, if hampered by Board of Trade inspectors and their instructions to surveyors?

Yours, &c.,
Boiler.

Manchester, 25th February, 1888.

BOILER AT THE HUYTON IRON WORKS.

Sectional Plan.

COMPULSORY INSPECTION OF STEAM BOILERS.

To the Editor of "Industries."

Sir,—The first part of the letter of your correspondent "Economiser," dealing with the above question in your last issue, being chiefly personal to myself, and an ordinary sample of would-be smart writing, I will pass it over and come to what I take it are the real points under discussion. It may be as well, however, to say here that I have not any knowledge of, or connection with, the Board of Trade or its officials, or with any boiler insurance company, and so write from a perfectly independent and unprejudiced standpoint. In the first place, would it or would it not be advisable to have all the steam boilers in the kingdom inspected? I think the general consensus of opinion is that it would be advisable. The next question is, What is the best method of carrying this out without interfering with the liberty of the boiler owner? Two plans at present

Digitized by Google

are suggested: (1) Inspection by Board of Trade officials; (2) inspection by boiler insurance companies, under Board of Trade direction. Of these two there is little doubt the latter is to be preferred. I think that no boiler owner who looks well after the condition of his plant, and employs a competent man to attend to it, would have any objection to an inspection, if arranged to suit his convenience. The chief objector would probably be the greedy or ignorant owner, who uses an old boiler, often worn or corroded to a dangerous extent, without troubling or caring about inspection, or the lives of the people in his employ. That there are many such boilers in use can be proved to demonstration, notwithstanding the denial of your correspondent; and if he will peruse the last issue of your contemporary *The Engineer*, he will find ample corroboration of this assertion, and also of my contention as to the advisability of granting certificates of competency to boiler attendants.

Supposing it is conceded—at any rate for argument's sake—that compulsory inspection is desirable, the point to be aimed at is the best system of inspection, at a moderate cost and with the least amount of friction between the boiler owner and the inspectors. Could not a Bill be drawn which would give a joint control to a committee elected by boiler owners and some of the Board of Trade officials? In cases where a great divergence of opinion exists as in this, *medio tutissimus ibis* has proved itself to be the best course to pursue over and over again. Some of your correspondents appear to discover the cloven foot in everything emanating from the Board of Trade; but I think it must be conceded that the Board in this case appears to be desirous to meet the wishes of engineers and steam users at large as far as may be, or they would hardly propose that a committee of sixteen experts be elected from the various Institutes, &c., to confer with a Select Committee of the House of Lords as to the best form in which to draft the proposed Bill. It must also not be forgotten that the introduction of a Bill of this kind comes within the province of the Board of Trade. If they should attempt, however, to pass a harsh measure to obtain and retain in their own hands undue power, that would press heavily on boiler owners, I should as a person affected—if on no other grounds—be one of the first to help to oppose it. They appear, however, on this occasion to be willing "to give and take." If I remember rightly, some of the Government Bills for the inspection of mines met with considerable resistance in certain quarters; but hardly anyone will deny that on the whole they have acted beneficially.

Yours, &c.,

M. Powis Bale.

Appold-street, London, E.C., 27th February, 1888.

TECHNICAL EDUCATION.

To the Editor of "Industries."

Sir,—There seems to be considerable difficulty in stating clearly what are the aims and what are to be the processes of Technical Education. The various meanings attached to the name, however, seem to point in one common direction, that, viz., of making the education of the people in all its grades bear upon their everyday life and work. This seems in every way desirable, for two reasons—first, as likely to increase the productive power, and therefore the material wellbeing of the country; and second, as likely to give that higher tone of intellectual interest to every, even the humblest, occupation which serves at present to differentiate what are called professions from what are called trades. The aim of technical education, thus broadly stated, may be regarded as that likely to be generally accepted as both desirable and attainable.

Greater diversities of opinion, however, exist as to the way along which we must travel to reach the desirable destination. The perusal of the articles by Mr. Henry Dyer, C.E., which appeared in *Industries* of the 27th January, and the 3rd and 10th ult., has prompted me to write this letter as a contribution to what I should hope would be a considerable correspondence upon a question that is likely to occupy public attention for a long time, and which involves issues so vast that a false start would be disastrous. The reception of the recently passed Act for Technical Education in Scotland shows, I think, that the Act has probably been a piece of premature legislation, not enacted in response to any clearly expressed public demand, nor formulated as the result of careful discussion by educational authorities. That example, if I am right in calling it premature in the sense above indicated, ought to stimulate free discussion on the subject, in order that the larger interests of technical education in England may be not rashly but speedily legislated for.

Now, in working out the problem of technical education for the country, it is necessary to remember that the education must address itself to probably three different classes. These are: (1) Actual operatives, who form the bulk of the community; (2) employers, actual or potential, and managers, actual or potential; (3) a class who would fall under neither of the above, but who, if the system were once in working order, and actually deserving of the name "education," would find it acceptable as a substitute for what may be called the philological education on which pupils and students spend so large a portion of their time. This class would naturally be small to begin with, but would increase in proportion to the recognition of the educational value of the studies inaugurated under the new system.

From this division it follows that technical education will fall into the two grades of primary and secondary, with, of course, a still higher grade, that may be said to already exist in present colleges and universities. The question that next arises is, What is the subject matter of this education?—from what portion of the wide fields of knowledge are we to gather? The answer, of course, is "Science," but in other than its usual academic sense. It is a commonplace remark that every art has its corresponding science, and while the arts are learned in workshops and factories, and the sciences in schools and colleges, they are usually learned by different persons, and the correspondence between the art and the science is learned by few. Indeed, this connection or correspondence may in a general way be said to constitute all the new matter with which technical education must deal. We certainly need more science teaching and more teaching of the arts also, but the connecting link is the matter which is most conspicuously wanting. It is fortunately a fact that working people take new interest in their work when they learn that the individual facts that daily come before them are examples of the great general laws of sciences of which they previously were ignorant, just as a student of science is delighted when he observes for the first time, in some homely process of trade, a concrete illustration whose existence he never dreamt of before, of one or other of the grand generalities with which he was familiar. To such persons the science and the art both have greater intellectual interest after the connection between them becomes clear.

To revert for a moment to the division I indicated of the classes to whom technical education addresses itself, I may now say that the educative processes to be carried on must differ according as we are dealing with the first class or with the second. The first will have an empirical knowledge of facts; they must be taught to scientifically correlate them. That is, they must be taught more science than art. The second class may be presumed to have had a scientific training, as well as a knowledge of their trade; they must be carried further in each. To young people of both classes the teaching of the trade and of its corresponding science must go on simultaneously.

The first step in organising a system of such teaching of applied science is to discover if nothing is made, or can be made, of existing educational organisation. We have, broadly speaking, four classes of institutions to which we must look. These are the Elementary Schools, whose function is all important as the basis of everything; the Secondary Schools, in which the education has hitherto been mainly philological, but which are being gradually adapted to more modern ideas; Intermediate Schools, as they may be called, such as colleges and other variously styled institutes, in which the bulk of the teaching is scientific and modern: and, lastly, the Universities, in which the sciences that are taught are either in the high regions of pure theory, or applied to the needs of the one profession of medicine and surgery. We must therefore adapt, as much as is necessary and possible, these existing institutions, and establish whatever new classes or schools are required. But it is perfectly appalling to think how much adaptation is necessary. In the highest region, university reform, long talked of in Scotland, may do a good deal. But even in the elementary schools there may be said to be absolutely nothing taught with even a remote reference to technical education. Mr. Dyer's scheme is based upon the elementary school; but the system of elementary education must be transformed before anything can be made of it. After reading, writing, and arithmetic get their due share in our Scottish schools, grammar, geography, and history are taught, and these, with sewing, fill up all the available day school time; for each of these subjects is systematically drafted in a four year's syllabus, and attention to them is secured by a system of grants graduated according to the quality of the teaching. Elementary optional science, which is the very thing we want, is prescribed as an alternative grant-earning subject—alternative to geography and history only—but that subject is all but ignored. The reason for this neglect of science is the nature of the teacher's own education, which is usually on the traditional philological lines. The first necessary step, in my opinion, would therefore be such alteration in the training of elementary teachers as would make them able and willing to give their oral lessons a tendency towards those parts of science which corresponded to the trade of the locality. The time for this might be easily found by giving less time to grammar, &c., which are taught with probably unnecessary thoroughness, considering the greater value of subjects which they exclude. The aim must be, of course, to awaken interest and inquiry, not to cram facts for an examination. Were this double adaptation effected—adaptation of teacher and of school curriculum—the primary schools might be, as they ought to be, an excellent foundation for more definite technical education.

So far the question of expense hardly arises. Neither need it arise to any great extent in connection with the adaptation of secondary schools, for the high fee chargeable would go a long way to pay expense. But most boys of fourteen who leave an elementary school go right off to trades, and cannot get the more definite education of the secondary school. At this point appear what must form the new feature of our educational system—continuation classes mainly in science for boys engaged in learning trades. A great difficulty in the way lies in the fact that division of labour and the use of machinery are now carried to such an extent that in many trades the workmen can hardly be said to be tradesmen at all. For example, a riveter can hardly be called an engineer or a shipbuilder; a man who can do nothing but bore holes in metal plates can hardly be called a skilled mechanic. So that apprenticeship does not mean what it used to mean. And this defective teaching of the practice must be made up to some extent simultaneously with the teaching of the theory. This, I understand, is systematically carried out in the works of some engineering firms. The apprentices have science classes bearing on their trades as part of their apprenticeship, the practice and the theory being taught side by side *in the works themselves*. This would seem the very perfection of technical education for that class at least, and they are, after all, the main element in the case. It is quite conceivable then that in many districts where there is one staple industry, model factories or workshops, with class rooms attached, might be found the best type of technical schools. In large centres of population with a variety of trades, a separate institution for each trade would be most advantageous. In smaller places one such institution might have more model workshops than one upon a smaller scale. The actual trade would be carried on and saleable articles produced. Indeed, a portion of the expense of the institution would be paid out of returns for the sale of products. A half-time system of attendance might be established for apprentices.

I cannot see, as Mr. Dyer sees, how university extension can do much for technical education. It is quite true that science lectures are a first rate foundation for technical education; but they can never do the work altogether. Besides, though we had a complete system of technical education, there would still be a blank that university extension alone is able to fill; for men and women are more than mere wage earners, and must have wider intellectual interests than in their trades only. There are, therefore, numerous branches of knowledge that will have high educative value for men and women of all occupations, but which are not in the least connected with any trade.

Neither is there much likelihood of the universities going in the direction of technical education. Much is hoped for from university reform bills; but such a great transformation as is implied in converting the universities into technical colleges is hardly among the changes that are to be hoped for. I can see no harm in some form of certification or license (or degree, as Mr. Dyer seems to desire) for the best technical students. Such certificates would soon have a very high value. When that stage is reached the existence of prospective certificates is as good for an institution as an endowment would be.

In all this the great danger is a hasty race after results, expecting to reap fruit off a newly planted tree. If the results of technical education are to be valuable they will be slowly attained.

Yours, &c.,

THE INDUCTOR DYNAMO.

To the Editor of "Industries."

Sir,—In the report of Mr. Mackenzie's paper read before the Society of Telegraph Engineers and Electricians given in your issue of the 17th ult., you apply the term "armature" both to the moving part of the machine and also to the fixed part. This, though technically correct, is rather confusing. The term "inductor" has already been applied by Prescott and Thompson to the moving armatures, and is a very convenient name for them. I propose, therefore, to call the moving part of the machine the inductor wheel, and to apply the terms primary and secondary magnets to the excited magnets and those in which the alternating current is generated, respectively. The term "armature," which is sure to give rise to confusion, is thus avoided altogether.

Sewage Treatment, Purification, and Utilisation. By J. W. Slater, F.E.S. London: Whittaker & Co.; George Bell & Sons.

Reviews.

Notes on the Lithology of Gas Coals. By James Paterson, C.E., F.G.S. London: Walter King. 1887.

This is the third edition of the author's "Notes" and "Analyses," and includes a large quantity of additional matter, which renders the book of greater usefulness to those interested in the chemistry and calorific values of the different varieties of coal and cannel. The first article on the lithology of gas coals was read some years ago, before the British Association of Gas Managers; but the tables of analyses of gas coals and cannels have been considerably augmented since the previous editions, and include upwards of two hundred complete analyses of British coals and two samples of Japanese coal analysed by Messrs. Newbigging & Paterson, for the Government of Japan. Nearly one hundred analyses of cannels are also tabulated with their respective yields of gas and coke, the quality of the former being given in illuminating power stated in candles and in grains of sperm per cubic foot. The per cent. of sulphur and of unsaturated hydrocarbons, as determined by the bromine condensation method, are also given in the tables. A useful table of the calorific value of English coals, as tested in Thompson's calorimeter by the so-called deflagrating process, forms an important part of the work, especially as these coals are compared in composition and calorific value with coals from other localities. The concluding pages deal with an inquiry into the chemico-physical relations between coal and cannel, in which the author brings forward geological and palæontological

Digitized by Google

evidence in support of his view that cannel coal beds have a similar origin to common coal, viz., that the difference in their properties is due to the larger proportion of gummiferous trees present in the primeval forests of the former. The influence of fish remains and molluscan and other oils upon the streak and fracture of cannel is also pointed out by Mr. Paterson; and his own views on the origin of anthracite, the abnormal conditions of many coal seams, and the distribution of petroleum are placed in appendices at the end of the volume. Mr. Paterson has evidently devoted much thought to these complex problems which are of such great interest to the geologist, and undoubtedly interest the reader; but we think that more evidence is necessary before some of his theories can be accepted as final. These theoretical discussions do not, however, prevent the book from being at the same time a very valuable work of reference to all those who desire to know more of the composition and physical properties of our English coals and cannels.

ELECTRO-CHEMISTRY: INORGANIC. By G. Gore, F.R.S., LL.D. London: Published at the office of *The Electrician*.

This short treatise consists of a collection of the facts at present known concerning the electrolysis of inorganic compounds. The first portion is devoted to a historical sketch of the subject and a brief account of the laws which govern the electrolysis of solutions. The matter is not treated from a mathematical point of view, but frequent references to the more important original papers on the subject are given. It is unfortunate that this part of the work is not now up to date, as the greater portion appears to have been written some time prior to the year of publication. A new edition, embracing the recent discussions on this subject at the British Association meetings, and the reports which Professor Lodge has drawn up, would materially increase the value of the work as a book of reference. The electrolytic separation of the gases and non-metallic elements and their chief compounds has considerable space devoted to them, while the behaviour of metallic salts under eletrolysis and the isolation of the metals by electrical means concludes the volume. The references given in this part of the book are chiefly to English sources, so that for complete information on several of the points touched upon it is necessary to consult Watt's Dictionary, reference to which is usually made for information as to the journal in which the original may be found. The author's own work on the electrolysis of the metallic fluorides is naturally given somewhat more fully, and such subjects as the self-deposition of metals, and the work of Raolt and Gladstone, and Tubes' experiments with metallic couples are included in the book. The author in the preface states that the treatise is essentially a scientific one, and that information of a technical character has been purposely omitted. The book will, however, be found of use to electrical technologists, as the more important manufacturing operations in which electrolysis plays a part are shortly described. Messrs. Elkingtons' process for refining crude copper, Morris & Johnson's methods for depositing brass and German silver, and the gold and silver cyanide plating solutions, are given. In this part, as in the former, the recent additions to the applications of electrolysis in the manufacture of aluminium by the Cowles electrical furnace, and the separation of metals from the ores, would increase the value of a second edition. A second volume is promised on the electrolysis of organic substances, in which we presume the author intends to include the electrosynthesis of carbon compounds when pure water is electrolysed with carbon plates, which is not alluded to in the article devoted to the electrolysis of water in the present volume.

THE ORDNANCE SURVEY OF THE UNITED KINGDOM. By Lieut.-Colonel T. Pilkington White, R.E. Edinburgh: W. BLACKWOOD & SONS.

The aim of this book is to convey to the general reader an intelligible idea of the National Survey, and this it does very successfully by giving a short popular account of what might seem at first sight a dry scientific subject, suited only for experts. It begins by giving the early history of the survey, which had its origin shortly after the "forty-five" rebellion, and was doubtless the outcome of that unhappy rising, for it contemplated a general map of the Scottish Highlands. It was undertaken by Generals Watson and Roy, and it was carried on by fits and starts for some years. It was not, however, until 1783 that arrangements were made for the conducting of a huge and delicate trigonometrical operation, which was in reality to form the nucleus or starting-point of that elaborate system of triangulation we now possess over these islands. Colonel White's book traces its history down to the present time, and explains in simple language the chief operations involved in the survey, and the computations necessary for making them available for use. Descriptions are also given of the scales of the maps, as well as an account of the controversies which have raged round the subject, and an account of the organisation of the survey, including the most recent changes which were made in 1880, when, in order that the whole work should be completed in 1890 instead of 1900, as was previously contemplated, the staff was almost doubled. This change, notwithstanding the difficulty of suddenly increasing so largely the strength of trained employés, was smoothly and most successfully accomplished, and the result promises to more than justify the forecast made of the acceleration of the progress which would ensue; for the pledge given to Parliament and the nation as to the completion of the Cadastral Survey of the United Kingdom in 1890 is certain to be kept, provided, of course, that the necessary annual funds continue to be voted, and no unforeseen causes of delay arise.

Comparatively few people have a clear idea of the various uses and objects of the survey, and therefore we may briefly enumerate them as follows: (1) military, and especially for laying out the national defences; (2) geodetic; (3) geological; (4) hydrographic, as supplying accurate coast details to the nautical surveyor; (5) archæological; (6) topographic; (7) for engineering purposes of all kinds connected with the construction and maintenance of water works, gas works, drainage works, telegraphs, roads, railways, canals, harbours, and so forth; (8) mineral survey; (9) parliamentary, in reference to standing orders; (10) sanitation, as under the various Acts relating to the public health; (11) delineation of the civil and ecclesiastical divisions of the country, hundred, parochial, &c.; (12) to facilitate the adjustment of jurisdictional areas; (13) census and statistical information; (14) the enclosure and reclamation of waste lands; (15) registration of title; (16) simplifying and cheapening conveyances of land, deeds of sale, leases, and all transfers of landed property; (17) for miscellaneous uses of general public or private interest. This is a long but by no means exhaustive list, but it is sufficient to furnish an ample *raison d'être* for the prosecution and maintenance of a national Cadastral Survey, and the work has been done in such a way as to evoke from foreign experts the unique encomium, "L'Ordnance Survey, œuvre sans précédent et qui devrait servir de modèle à toutes les nations civilisées."

FORTSCHRITTE DER ELEKTROTECHNIK. By Dr. Karl Strecker. Berlin: JULIUS SPRINGER.

We have before us the first and second parts of a work which it is proposed to publish in future quarterly, and which is a kind of synopsis of publications in scientific journals and patent abstracts referring to electrical engineering, which have appeared during the previous quarter. The matters treated are divided into five main parts. The first embraces electricity in its mechanical application; the second, electro-chemistry; the third, telegraphy and telephony; the fourth, measurements and scientific investigations; and the fifth, earth currents and atmospheric electricity. Each of these divisions is again sub-divided, and the manner of this sub-division will, perhaps, best be shown if we give as an instance the headings under electricity mechanically applied. These are the following: General theories of dynamo machines, electromotors, descriptions of types of machines, details of machines, regulators and prime movers for dynamo machines. Under each of these headings is a long list of references to publications in European and American journals, classified under the author's name, and in many cases references are given to patent specifications under the names of the patentees. Considering the great difficulties which the editor of a periodical magazine of this kind must experience at the start, the information contained is fairly exhaustive. There are a few omissions, but these in future numbers of the magazine will grow less as the organisation for collecting information becomes more perfect and automatic. Referring to this point, the editor says in the preface that he experienced great difficulty in obtaining many of the journals from which abstracts are quoted, and he addresses a request to the publishers of journals and authors to furnish him with proofs of their articles. In the table of references, the titles of the articles are given in the language in which they originally appeared, together with the name of the journal, page or date, number of columns and illustrations. The references are entered under consecutive numbers, and in the short abstracts of articles which follow the reference table, corresponding numbers are placed in the margin so that the author's name may be identified where it is not mentioned in the text. The abstracts are succinct and clear expositions of the original articles, or of the patent specifications. No attempt is made at independent criticism, as the work is merely intended for reference, and not as a text book. In some few instances the text is illustrated by simple diagrams, but in this respect we think the magazine might be considerably improved, since diagrams are as essential in a work of reference as in a text book. It would also seem advisable to add an index of subject matter, and of the names of authors and patentees to every quarterly issue, and not only as proposed to the last number of each volume. With these improvements, this magazine will become one of great utility to practical electricians and engineers. The fact that the abstracts are in German will only to a certain extent reduce the value of the book to English readers, for, as already stated, the tables of reference contain the titles of articles in the language in which they originally appeared, and form, therefore, a complete record of the more important articles and patents published in English.

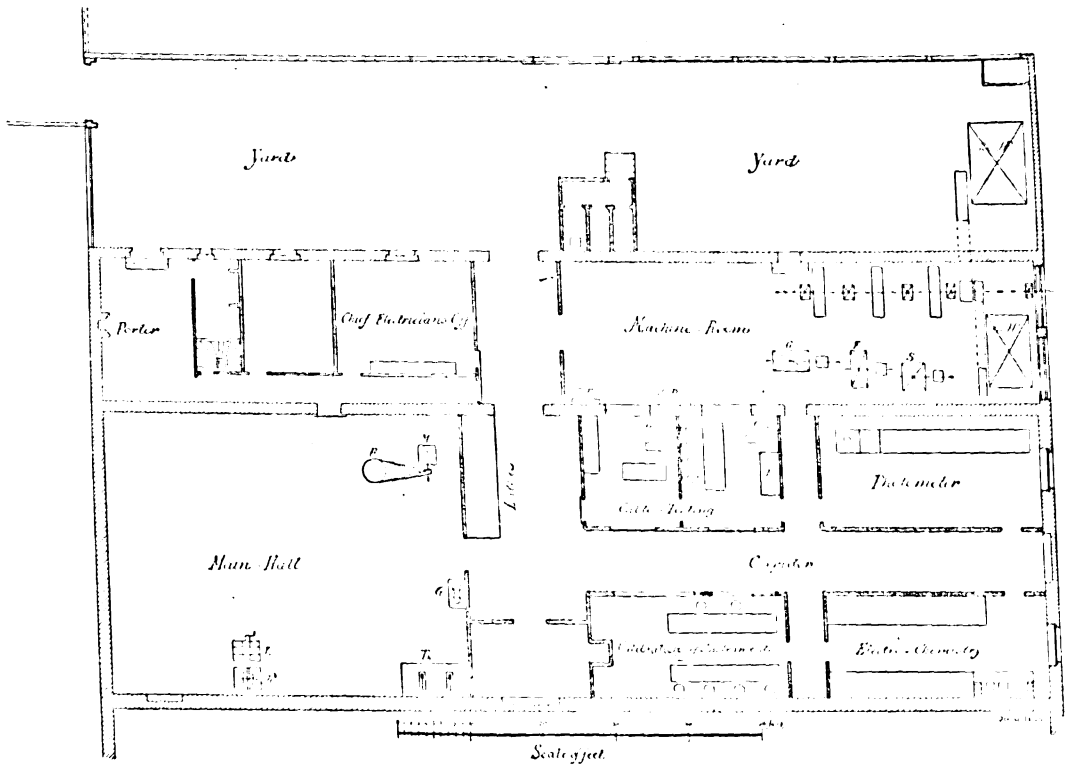
THE YEAR BOOK OF NEW SOUTH WALES FOR 1887. Special edition for the New South Wales Government.

This year book is evidently written to amuse and edify the colonial whose remoteness from civilised life deprives him of those comforts which he has sacrificed for present or prospective advantage. Round a camp fire, or in the dull and silent evenings in typical colonial cabins, even the reading of statistics, of cures for baldness, cures for corns, and the thousand odds and ends of information scattered through this little book, will be more valued than the most fascinating sensation novel on the shelves of a distant library. For intending emigrants, or for those who wish to inform themselves on the administration and institutions of the colony, the year book is invaluable. Colonial Acts of Parliament, *e.g.*, the Rabbit Nuisance Act, and the Crown Land Acts, information regarding the hiring of diamond drills and other boring machinery belonging to the Government, and notes on the Fishery Department, education, and colonial industries, afford the emigrant some notion at least of what he wants to know ere he makes up his mind to try colonial life. The manufactures which have been most successfully founded in New South Wales are, it appears, brass, lead, and iron work, machinery, woollen, leather, and leather manufactures (in this industry alone 4182 persons are employed), household furniture, paper, ornamental iron work, terra cotta, pottery, tiles, and bricks. This list shows no mean variety of industries, especially when one considers that with a territory almost as large as the combined areas of France and Italy, New South Wales has a population only slightly greater than that of any one of our three great cities, Manchester, Liverpool, or Glasgow. An interesting parallel is drawn in an essay printed in the volume between Victoria, whose fiscal policy is protective, and New South Wales, whose fiscal policy is that of free trade. The figures quoted to prove the relatively greater advance of the free trading colony are very striking, and are not to be lightly explained away by those who take an opposite view. The figures relating to shipbuilding, though diminutive from the point of view of shipbuilding statistics in this country, are relatively significant enough. The average annual amount of tonnage launched in New South Wales and in Victoria respectively in the years 1874-76 was 4439 tons and 1286 tons. In 1884 the figures were 7663 tons and 167 tons respectively. Doubtless other causes contributed to the expansion in the one case and the contraction in the other; but the difference in tariff is a striking coincidence. Among other interesting and important information in the year book is the fact that there is still unalienated land in the colony to the extent of 163,000,000 acres, and that nearly 150,000,000 acres of this is land suitable for either agricultural or pastoral purposes. The Board of Technical Education of New South Wales has among its departments agriculture, with four courses of lectures (one on wool sorting); applied mechanics; architecture, with courses on masonry and bricklaying; chemistry; commercial economy, with seven courses; domestic economy; geology, &c., &c.; and it organises besides free popular lectures on technical, scientific, and artistic subjects, in the Sydney Mechanics' School of Arts, four nights a week. Diplomas carrying the title Industrial Expert are given to those who pass prescribed examinations. There are some common sense ideas here that might well be applied to our educational system, partly fossilised as it is by tradition and convention. A list of wages ruling in the colony, with the cost of the chief items of a working man's expenditure, are given at the end of the year book, with advice to those about to emigrate.

BRITISH MINING. By Robert Hunt, F.R.S. London: CROSBY LOCKWOOD & Co.

This is a second edition, differing from the first issued some years ago in nothing but the price. It has, however, been revised, for the author tells us that though he has not thought it advisable to add to the original text, he has examined the latter with much care. In this statement we have his assurance that in the vast mass of facts which he has brought together in this volume of 882 pages, there is nothing which the experience of publication has shown to be inaccurate or of a doubtful character. The difference of price sufficiently distinguishes this new edition. So long as the work was within the reach only of the few who can afford to spend considerable sums of

Digitized by Google



money on books, its use was restricted to a narrow circle. In the hands of the many it will better fulfil the intentions of the author in undertaking so laborious a task as its compilation involved. By issuing it at a popular price "young miners, on finishing their education, will," he says, "be in a position to possess the book, while the experienced metal miner may have it at hand for consultation when in search of information on some particular subject." Doubtless those for whose benefit the reduction has been made will be quick to appreciate the advantage thereby afforded them, and we may safely predict for the second edition a much wider distribution than was possible for the first.

Mr. Hunt has used his unequalled opportunities well, and has drawn from every source known to him. He has selected wisely and condensed intelligently. Everything is arranged with a due regard to logical sequence, and, as the style is lucid, all is clear and forcible. These are merits not always to be found in writings on technical subjects. It is a book for the leisure hours of the student and the busy moments of the practical man. Even the general reader will find in its early pages matter to while away profitably a weary hour. That it is a trustworthy compilation goes without saying. No man, probably, was better qualified than the Keeper of the Mining Records to perform a task of this character and magnitude. He has done his best, and the result is necessarily worthy of our confidence. It is, however, to be regretted that the opportunity afforded by a new edition was not used to bring this important work down to the present date. Within the last five years considerable progress has been made in the science and practice of mining, and none could have known better than Mr. Hunt the true value of the improvements effected. New processes have been devised, more efficient machinery has been designed, more powerful or more suitable explosive agents have been discovered, more economical or safer methods of working have been adopted or proposed, and additional legislation has imposed fresh duties and difficulties on the miner,—all of which matters might with advantage have found a place in the second and popular issue of "British Mining." We also look in vain for examples of the best American practice, which, outside England, is acknowledged to be well ahead of our own. If these things do not yet come within the category of British mining, none could have done so much as Mr. Hunt to remove from us the reproach of lagging behind the times. The publishers will do well to bear this shortcoming in mind in view of a third edition. If it be deemed inadvisable to add to the dimensions of a book which is already bulky, a remedy may perhaps be found in greater brevity in the first two divisions.

The work is mainly divided into four books. In the first we have an instructive historical sketch in six chapters, occupying 180 pages, of British mining, from the period when Celtic Britain passed under the Roman rule down to the close of the eighteenth century. The second book, which consists of four chapters and fills a space of 316 pages, treats of the formation of mineral deposits. In these pages the author has "examined the characteristics of the metal-bearing rocks and elucidated the hypotheses which have been promulgated to explain the phenomena of the formation of metalliferous veins." This statement does not, however, comprehend the full scope of these four chapters, which form the principal feature of Mr. Hunt's treatise. In the compilation of this book, the author spent his best efforts, and it is here that the extensive knowledge and scrupulous care of the Keeper of the Mining Records becomes most strikingly visible. He has given us a minute description and, from some points of view, a detailed history of all the principal known metalliferous veins in the United Kingdom, and from this wide induction of facts he has endeavoured incidentally to build up a consistent theory of the formation of these ore deposits, introducing, as he says, "a few of the certainties of science into an arena of debate in which uncertainty prevails," in the hope of "convincing the miner that nature works according to fixed laws in regulating her subterranean operations." The third book will be regarded by many as the most valuable, or, at least, as the most generally useful. It treats of "Practical Mining," and deals with the subject in five chapters, occupying 314 pages. This division may, as we have already pointed out, be advantageously extended in the next edition. Book IV. represents the purpose for which the work was originally taken in hand by Mr. Hunt. He tells us in the preface that, as a member of the Royal Commission, appointed in 1866, to inquire as to the quantity of coal annually consumed in this country with a view to determine the probable duration of our fossil fuel, he was brought constantly into contact with our great metallurgists, who pressed upon him the necessity of obtaining, if possible, a solution of the same problem in relation to metal mines. This question is learnedly examined in the fourth book, divided into five chapters, to which is allotted the space of 72 pages. The work, which contains upwards of 230 illustrations, ends with an appendix of useful statistics and a glossary of mining terms.

It is interesting, now, when the competition of German workmen, both abroad and in this country, has become one of the burning questions of the day, to learn from Mr. Hunt that Queen Elizabeth first introduced our new formidable Teutonic rivals to these shores. We are told that about the year 1562, acting on the advice of her Council, she sent to Germany and obtained the services of a large body of practical miners, whom she distributed over the various mining districts of the kingdom, "for the purpose of improving the British workman." During the next twenty years, there appears to have been a constant influx of German miners, to whom was granted a monopoly of all the mines in Wales, and in eight English counties besides; so that, practically, the whole mining industry was at that period in the hands of these foreigners. They introduced a better system of working and more perfect processes of dressing the ores. But the Cornish miners were proof against the "improving" influences of their foreign teachers. "With true Celtic obstinacy," says our author, "they remained satisfied with the methods used by their forefathers."

THE PARIS ELECTRICAL LABORATORY.

THE PARIS ELECTRICAL LABORATORY.

By the courtesy of M. de Nerville, the general director of the laboratory established by the International Society of Electricians at Paris, we are enabled to lay before our readers a plan of the building, and some information regarding the machinery and apparatus installed. The building is one storey high, and contains a machine room, a room for cable testing, where resistance, capacity, and insulation of conductors will be measured; a photometric room, an electro-chemical laboratory, a room for the calibration of measuring instruments, and a main hall for experiments with dynamo machines, transformers, and other appliances. The disposition of the various rooms will be seen from our plan. In the yard adjoining is placed a 20 h.p. portable engine lent by Messrs. Weyher and Richmond for the modest rental of one franc per annum. Power is transmitted from this engine by a belt to the countershaft in the machine room from which the different dynamos are driven. Within this room there is also a 12 h.p. Otto gas engine, so arranged as to work on to the same countershaft. In our illustration S is a Gramme dynamo made by Messrs. Sautter-Lemonnier and Co., and having an output of 300 ampères at 70 volts; E is a 100-light Edison dynamo, and G an alternating current Gramme machine, whilst S B are two switch boards, one serving for the continuous and the other for the alternating currents. In the photometric room is fixed a large Bunsen photometer, with 13ft. scale, and with the necessary standard lamps and a Dumas and Reynault balance for weighing the consumption of oil. In the electro-chemical laboratory is a large number of instruments for making current measurements by the deposition of silver and other metals, a branch of the subject which has already received special attention from M. de Nerville during his work in connection with the determination of the legal ohm. In the calibrating room are standard mercurial resistances, three Duprez-d'Arsonval galvanometers, and one Mascart electrometer. This room will serve for standardising commercial voltmeters and ammeters. In the cable testing room is a very complete collection of instruments, comprising Wheatstone bridges, Thomson's mirror galvanometers, and Deprez galvanometers, marked G on our plan; and one of the new Carpentier dead beat electrometers. There is also a battery L of 100 Leclanché cells for capacity and insulation tests. The main hall is as yet sparsely furnished with apparatus. There are two Thomson graded galvanometers, Th.; a small hand gramme dynamo, L; a Wimshurst induction machine, W; a Gaulard & Gibbs' transformer, G; and a 1 h.p. Gramme motor, driving a Romilly pump. The large hall is to be used for conferences and special experiments, such as the photometric measurement of lighthouse arc lamps, for which the Bunsen photometer is not large enough. The lamp will, in this case, be placed at the extreme end of the corridor, and the photometer at the opposite end of the hall, the available distance being about 120ft. As has already been reported by our Paris correspondent, the laboratory was opened on the 10th of February.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

The adjourned discussion on transformers and the distribution of electricity by their means was resumed on Thursday, the 23rd ult., by Mr. Lamb, one of the gentlemen who had made calorimetric experiments with the transformer to which Professor Ayrton referred at the previous meeting. Mr. Lamb described the apparatus used, and exhibited some interesting efficiency curves, showing that the true efficiency of a transformer, as determined by the calorimeter, is throughout greater than the apparent efficiency determined by a wattmeter, or by the indications of a dynamometer and voltmeter.

Mr. Gordon regretted that so much labour and ingenuity should be wasted on problems connected with alternating currents, because there was no future for them. He himself was one of the first to use alternating currents at the large installation put up by him at the Paddington railway station, and this system is still at work, with satisfactory results; but notwithstanding this success, he had come to the conclusion that the employment of alternating currents is beset with so many difficulties as to make the system unfit for general adoption. One of the objections is the large size of dynamo. He himself has constructed alternating current machines which were larger than any other machine produced up to that time, and although it may be very satisfactory for an engineer to see these huge armatures revolving, it was less satisfactory to the shareholders of the company. A 200 kilo.-watt machine would require an armature 10ft diam., whereas a 100 kilo.-watt low tension continuous current machine could be made with an armature only 16in. diam. Another objection to the system was that the whole of the power must be developed in one machine. He did not think it was possible to couple

Digitized by Google

several alternate current machines together without producing considerable jumping in the lamps, which would of course shorten their life. Mr. Gordon exhibited an interesting diagram, showing that in a residential district the maximum number of lamps is only on for an hour and a half each day, viz., from 6 to 7-30 p.m., whilst from one-half to two-thirds of this number is on from 5 or 6 o'clock in the afternoon till 10 p.m. From 10 o'clock to about 3 a.m. the number of lamps alight steadily declines, and from 3 a.m. to 3 p.m. in winter it is only a small fraction of the total number fixed. The uneven rate of consumption is a great difficulty, because machinery must be provided equal to the large consumption, and the plant is therefore in excess of the requirements for twenty-two hours out of the twenty-four. He preferred to supply the lights from storage batteries, which could be charged steadily during twelve hours, or even during twenty-four hours daily, by which means small engines and dynamos only are required; but being kept at full work for a longer period, the total output is the same as with a larger plant spasmodically worked, whilst the efficiency is of course much higher. Engineers knew perfectly well that it was uneconomical to work engines much below their power. So convinced was he of the superiority of lighting by batteries, as compared with the direct system, that he was now engaged in putting up a central station at Whitehall Place, where it will be possible to do what gas companies are doing, viz., to utilise the waste products. In this case the waste product is exhaust steam, which will be used for supplying hot water to the baths and heating apparatus of the residential chambers for which the central station is being erected. Mr. Gordon, after collecting statistics on the amount of gas lighting done in London, has found that there are about 125,000 gas jets to the square mile.

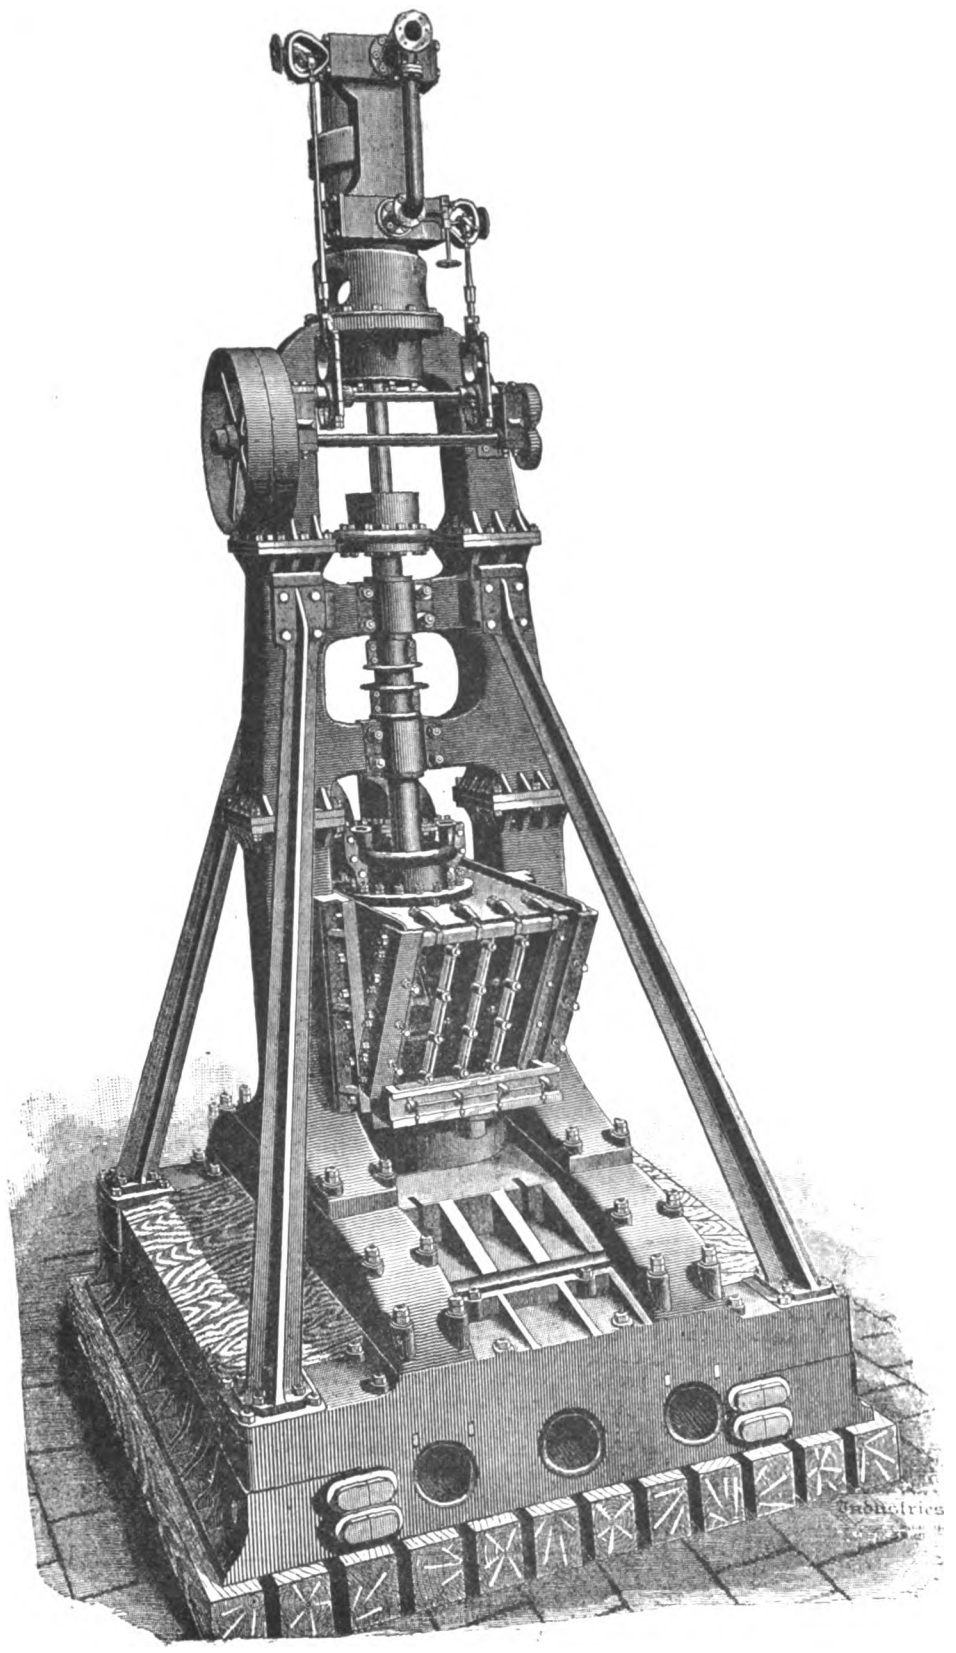
Mr. Crompton, who followed, spoke in the same strain. He thought Mr. Kapp's paper was rather dry, and he would therefore try to infuse a little life into the discussion by treating it from the commercial side. He did not deny that the transformer system had developed to a certain extent in America, but this was merely due to the fact that Americans would put up with any lighting, no matter how bad. It had also been developed to a considerable extent in London by the Grosvenor Gallery Company, and in this connection he thanked Sir Coutts Lindsay very cordially for being engaged in educating Londoners in the use of the electric light, and teaching them to put up with scintillations instead of good steady lighting. He thought that the clients of the Grosvenor Gallery could not be very fastidious, and it would be very easy for him or any other electrical engineer to satisfy their demands in the future. He did not believe that it was possible to work alternate current machines in parallel, and therefore it was necessary to do the whole of the lighting from one huge machine. This entailed a considerable waste of power when the demand for light was small, and therefore he thought that the average efficiency of the system must be exceedingly low. They were told by Professor Ayrton that the transformer he tested had a very high efficiency. That may be so, but what he wanted to know was the efficiency taken commercially, viz., from the coal bill to the money received for the sale of the current. This he ventured to say would be very unsatisfactory to the supplier of the electric light on the alternate current system. He drew attention to the last paragraph in Mr. Kapp's paper, where the author said that his network of mains would be available for use with batteries if at a future time the change of system could be effected. He thought this showed that the author himself did not believe very firmly in transformers. The speaker had already adopted the battery system in several installations, and found it exceedingly economical. There was no need of employing currents of 2000 volts, as it was quite feasible to light a district a mile away from the generating station by currents of 500 volts, and yet to have comparatively small mains.

Mr. Esson did not think that the author's assumption regarding the curves of electromotive force and current were consistent with actual facts. He doubted that a dynamo which contained iron in its armature could give a true sine curve. This was shown on a wall diagram on which was drawn a true sine curve, and a curve calculated by Mr. Esson for a particular dynamo. If then the curve be not a sine curve, the graphic method of the author he thought became useless.

Professor Perry dealt with the same subject, but came to a totally different conclusion. He thought the current given by any dynamo might with very little error be considered to follow the true sine curve. It was well known that a curve of any shape could be considered to consist of a true sine curve with other sine curves of the second, third, or fourth order superposed. Now the action of the transformer was to smooth down the ripples thus formed, and this action was the stronger, the more marked were the ripples. From this it followed that whatever may be the shape of the pole pieces or the disposition of the iron in the armature, the current passing through the transformer would follow very nearly a true sine curve. The difficulty of employing alternating current machines in parallel he did not think was insurmountable. It would be perfectly easy to contrive an instrument which would permit of the coupling up to be done only when the two machines have come into synchronism, and the same instrument might be used to regulate the power and speed of the engines, so as to maintain the synchronism.

Mr. Mordey could not agree with the author that it would be well to keep the transformers out of the houses, and to employ a proper low tension distributing network. He thought that by doing this one of the great advantages, viz., cheapness in distributing plant, would be lost. He would prefer to give each consumer his own transformer, or at the most to employ one transformer in common for two houses. Referring to the question of lag, he described an interesting experiment which apparently showed that there was no appreciable lag. In the first experiment he had two transformers. The thick wire terminals of the first connected with the dynamo, the fine wire terminals of the same transformer were connected with the fine wire terminals of the second transformer, and between the thick wire terminals of the second transformer would therefore be produced the same potential difference as that given by the dynamo. If now one of the thick wire terminals on each transformer were connected by a short wire, and a voltmeter was inserted between the remaining two thick wire terminals, this would indicate either the sum or the difference of the potential difference existing between each pair of terminals. If there were an appreciable lag the sum would be somewhat smaller than twice the potential difference of the dynamo, and the difference would be somewhat greater than zero. If there were no lag the sum would be exactly twice the potential difference of the dynamo, and the difference would be exactly zero. To his surprise he found that this was actually the case, and even when he had coupled six transformers in the manner here described, the total potential difference over the whole series of six was exactly six times that existing between the terminals of the dynamo. This experiment seemed to show that there was no appreciable lag.

Mr. Wright could not agree with the author that the shell transformer was inferior to the core transformer. He himself had adopted the shell type because most of the heat was produced in the iron, and for this reason he thought it wise to place the iron outside.



Professor Sylvanus Thompson thought the distinction of transformers into shell and core transformers was not a very definite one, as it was impossible to say, in some cases, whether a particular transformer belonged to one or the other class. The graphic method of the author was certainly very simple and of practical use, because it enabled engineers who had no special mathematical training to solve problems connected with transformers. Mr. Esson's objection that the curve was not a true sine curve, he could not share. He had already, on previous occasions, expressed his opinion that the transformer is the very best possible apparatus for toning down the ripples in the curve, and altering its shape to that which corresponds to a true harmonic function. He thought that before high pressure service by means of continuous currents could be obtained, it would be absolutely necessary to improve the commutator of the dynamo. Mr. Crompton mentioned 500 volts as the highest pressure he intended to apply. This he thought an insufficient pressure if economy in mains was the object. The reason why Mr. Crompton adopted this low limit was simply that he could not get an ordinary commutator to work satisfactorily with a pressure of 2000 or 3000 volts. All the successful high tension machines had special commutators, but in the alternating system this difficulty was entirely overcome.

After a few remarks from Mr. Evershed and Mr. Kent, the President called upon Mr. Kapp to reply. The space at our disposal does not permit of our mentioning the various points touched upon in the reply, and we must, therefore, limit ourselves to that portion of it which had the greatest practical importance, because dealing with the comparative merits of the rival systems of supply brought forward at the meeting. Referring to the remarks made by Mr. Gordon and Mr. Crompton, the author did not dispute that distribution of electricity by means of secondary batteries was preferable to distribution by transformers; but before they could adopt the more perfect method it was absolutely necessary to have a reliable secondary battery. He himself had not met with such a battery, and if Mr. Crompton could bring one forward, he should hail its advent with delight. All the arguments which were used by these two speakers on that evening might with equal reason have been used three or four years ago; but they were not used, simply because the speakers had at that time no confidence in batteries. If a battery could be put on the market which would be as reliable and as efficient as a transformer, and the cost of which would not be excessive, the author himself would be amongst the first to recommend its adoption for central station lighting, and that he did not doubt the ultimate discovery of such a battery might be seen from the concluding paragraph of his paper, where he advised that a secondary network should be laid down in the streets in such a manner as to be available for use with batteries at any future time. Mr. Crompton's objection regarding the inefficiency of transformers when these are worked at low output, was met by the diagram which Professor Ayrton had exhibited on the wall. They would see that even with an output as low as a third of the normal the efficiency was still 85 per cent. It would never be necessary to work transformers below this output, because if the consumption decreased sufficiently they would simply switch off certain transformers on the network, leaving the work to be done by a smaller number, which would then be worked to half or three-quarters their capacity. Great stress had been laid by Mr. Gordon on the fact that the maximum number of lamps was only on for a very short time during the day, and that the plant must, therefore, be very much too large for the supply required during the rest of the time, and also be worked uneconomically. The latter objection, he thought, had been met by some of the speakers, who showed that machines could be worked in parallel, and that it was therefore not necessary to do all the lighting with one huge machine. As regards the other objection, this applied equally to batteries, and where it was even of greater weight, because for equal output batteries were more expensive than engines and dynamos. The author's programme was to adopt transformers and alternating currents for the present, and to retain them only as long as they could not get a reliable battery. If they could get such a battery, he would advocate to discard the alternating current machines and the transformers. This would entail a loss of only 10s. per lamp fixed, which might be taken as the cost of dynamos and transformers; and when they considered that the central station, boilers and engines, the network, the house wiring, and the lamps would remain equally useful after the change, they would see that the loss entailed by the change was really very trifling.

The President then called upon Mr. Mackenzie to reply to the discussion. Owing to the lateness of the hour the reply was necessarily brief; but we have been favoured by Mr. Mackenzie with some notes of his written reply, which he is sending to the Secretary of the Society, and the following is a short abstract: In reply to Professor Ayrton, who had asked whether compound winding of transformers had ever been tried at the Grosvenor Gallery, Mr. Mackenzie said that some experiments had been made with an apparatus consisting of a single coil of fine wire, placed in shunt to the primary of the series transformer. The coil surrounded a core consisting of a bundle of iron wires, which could be more or less inserted to suit the requirements of the secondary circuit. The results were, however, unsatisfactory, the coils always being burned up after some time, and the idea was finally abandoned. Mr. Bernstein's suggestion of using a fusible contact plug as a safety device the author considered quite feasible. It would not only be cheaper than the apparatus devised by Captain Cardew, but it was also free from the objections which are justly urged against the proposal of putting any point of the secondary circuit to earth. In reply to Mr. Atkinson, the author said that fluctuations in the strength of the exciting current had been observed with the Kingdon dynamo, though these fluctuations were not very great. They were probably due to the cause mentioned by Mr. Atkinson. The author did not intend to convey the impression that the fly wheels of existing engines should be altered to suit the Kingdon dynamo, but that in designing new plant for a central station, the fly wheel of the engine, which is necessary to insure steady running, could be made to form part of the dynamo, and thus combine two functions in one. The object of arranging the machine into various circuits was with a view to cut out certain of these circuits as the consumption diminished, so that the remaining circuits would be worked at maximum efficiency. With reference to Mr. Crompton's question regarding the actual cost of working the Grosvenor Gallery installation, the author thought Mr. Crompton had asked rather too much. Many of his objections against the alternating current system had already been answered by other speakers. There could be no gainsaying the fact that the transformer system had made great headway, and this would never have been the case had it not possessed sufficient merits to place it before all others for the general distribution of electricity. The author himself expected to see Mr. Crompton before long become as warm an advocate of the transformer system as he had many years ago been an opponent of electric distribution by secondary batteries. Professor Sylvanus Thompson and other speakers had taken exception to a statement in the beginning of his paper as regards the Faradaic theory. He wished to point out that neither he nor Mr. Gaulard had ever denied the Faradaic theory of induction; but Mr. Gaulard had from the first believed that this theory, as exemplified by Ruhmkorff, was not a proper basis for the construction of transformers.

AN IMPROVED STEAM STAMP.

AN IMPROVED STEAM STAMP.

We are indebted to our American contemporary the *Engineering and Mining Journal* for the accompanying illustration, showing a steam stamp of the latest pattern, as constructed for the Tamarack Mining Company, by Messrs. E. P. Allis & Co., at the Reliance Works, Milwaukee, Wisconsin. The frame and bed plate of this powerful machine are made entirely of cast iron, and are securely bolted and braced together, thereby avoiding the excessive wear experienced in some forms of steam stamps. The bed plate consists of a massive casting, connected to the timber foundation by anchor bolts. There are nine spring timbers resting on the side sill of the bed plate, and arranged in such a manner that the worn out timbers may be easily replaced by new ones. The mortar rests on a solid cast iron bed plate 18in. thick, and weighing 18 tons, and is secured thereto by an angle iron frame bolted to the stamp frame, and forming a guide. This arrangement allows the mortar a slight vertical movement at each blow of the stamp head. The guides for the stamp shaft consist of loose shells, lined with Babbit metal, and may be easily removed when worn and re-filled. The stamp has fitted to it a vertical cylinder, 20in. diam. and 24in. stroke. The valves are actuated by two shafts, shown in our illustration. The lower one of these shafts is driven by a belt and pulley, and the motion is communicated to the upper shaft by means of elliptical spur wheels. In our illustration both valves are actuated by the upper shaft; but it has been found that better results may be obtained by connecting the upper valve to the upper shaft, which has an irregular motion, produced by the elliptical gear, while the lower one is connected to the lower shaft, having a regular motion. It is claimed that in this arrangement the valves are moved in such a manner as to leave both steam ports fully open during the down stroke, thereby admitting the steam at full pressure through the top port, and insuring a free exhaust through the bottom port. The amount of steam admitted during the up stroke is regulated by a separate valve placed in the steam pipe outside the lower main valve. This regulating valve may be adjusted to give any required pressure for lifting the stamp, while it does not interfere with the free opening of the exhaust. This arrangement has been patented by Mr. E. Reynolds, and we understand that it admits the perfect adjustment of the valves to suit any class of work. A scale is marked on the eccentric and shaft collars for giving the stamp any desired speed. The piston rod is connected to the stamp shaft by a circular disc encased in an iron cover bolted to the stamp shaft, and arranged in such a manner that it may be taken out without removing the piston. The space between the disc of the piston rod and the cover of the stamp shaft is filled with pure india-rubber packing. The piston and piston rod are made of steel, and all the bolts of the best Swedish iron. The water used in stamping is admitted round the stamp shaft, so as to protect it from sand. The stamps are estimated to last six years, whereas the shoes want renewing every two or three months. The capacity of this machine is 225 tons in twenty-four hours, on a consumption of 1 ton of coal for every 34 to 36 tons of ore, and with a speed of ninety to ninety-two strokes per minute. Messrs. Allis & Co. have now in course of construction a stamp in which the spring timbers will be left out entirely, and their place will be taken by a cast iron bed weighing 40 tons, and it is expected that greater efficiency will be attained with this arrangement.

THE SOCIETY OF CHEMICAL INDUSTRY.

The Oxidation of Camphor Oil.—At a meeting of the above Society, at Burlington House, on the 20th ult., Mr. C. T. Kingzett in the course of a paper set forth that of late camphor oil has to some extent come into the market as a substitute for turpentine in the manufacture of varnishes. If camphor oil be freed from camphor by freezing, and then be moderately heated, more camphor is formed; in fact, by oxidising camphor oil, camphor is yielded, and peroxide of hydrogen is formed. The chemical reaction of water upon some partly oxidised substances seems to be the formation of peroxide of hydrogen. The presence of such substances in the leaves of trees has an influence upon natural sanitation; the wind blowing over the leaves of certain trees in New South Wales and South Australia, gives rise by oxidation to an aggregate of millions of tons of peroxide of hydrogen, which must exert a beneficial influence upon the health. He had found that from sunflower oil treated by his method for the oxidation of camphor oil, no peroxide of hydrogen is formed, hence he concluded that sunflower oil does not contain any terpene.

The Chairman, Mr. Thomas Tyrer, said that some time ago a rather too oily camphor, with an aromatic smell, was in the English market. It was very cheap, and was undoubtedly produced from camphor oil; and that lately it had increased in value.

The New Dye "Primuline."—Mr. A. G. Green read a paper on "Primuline," a new dye manufactured by Messrs. Brooke, Simpson, & Spiller, who exhibited upon the lecture table a large collection of coloured fabrics illustrating the results obtained. Mr. Green said that all the cotton dyeing colours hitherto known might be classified as follows: (1) Hydroxy compounds capable of forming stable lakes with oxides; (2) insoluble colours formed in the fibre; (3) strongly basic nitrogenous colours; (4) non-nitrogenous natural dyestuffs; (5) azo cotton colours. Alizarine is a type of the first group. In group (2) soluble constituents are brought together in the fibre, in which they then produce the colour safranine; a pink colour is a type of the third group. In group (4) only three colours are known—anatto, turmeric, and saffron; no colours at all resembling them have been produced artificially. The colours of the fifth group have only been known since 1884, and the most important of them are those obtained from benzoline. Groups (1) and (2) form the fastest colours of all, because they are in the fibre; but if in addition one of the constituents had a natural affinity for the fibre, it ought to give the fastest colour of all, or at least a colour as fast as any of them; and the "primuline" colours discovered by him had the desired characteristic. A skein of cotton dyed with it alone was fairly fast, but not so fast as the colours produced from it by subsequent treatment of the skein. The method was to first treat the primuline with nitrous acid, and next with a phenol. A colour is then formed in the fibre. The primuline itself produces a pure primrose colour, and is applied to the cotton in boiling solution, containing a little soda, to "diazotise" it. It is then treated with a mixture of nitrite of soda and hydrochloric acid, and takes an orange colour, upon which any colour can be built up by the aid of phenols, especially varieties of reds, oranges, and yellows, and the colours are quite unaffected by acids. He then boiled some pieces of cotton dyed primuline red, also some other pieces dyed Congo red, in dilute hydrochloric acid. The Congo red went dark purple, practically black; the other dye was unaltered. Stuffs dyed by the aid of primuline may be re-diazotised, and again treated

Digitized by Google

with the particular phenol, with the result of greatly deepening the colour. The discharge for primuline colours is a strong reducing agent. He used true sodium hydrosulphite, made by boiling sodium sulphite with zinc. This, applied hot, restored the cotton to its original primuline colour. By using primuline as a basis or mordant, cotton took methyline blue much better than would otherwise have been the case.

Mr. Nettlefold said that cotton treated with naphthol, and afterwards dipped into phenols, gave beautiful scarlets and violets, which would resist the action of reducing agents. He supposed that primuline must be a new base, and wished Mr. Green to tell the meeting its composition. In law courts it was often a matter of dispute whether colours were inside or outside the fibre. Mr. John Spiller remarked that an infinite number of colours could be built up by using primuline as a mordant.

Dr. Messel wished to know if the said colours were fixed to light and soap.

Mr. Green replied that the peculiarity of his process was that primuline itself was a real dye, so that the fabric could be thoroughly washed before beginning to impart to it another colour by means of a phenol. Other processes would not stand this washing. The colours were fast to soap, and would resist the action of light as well as any ordinary colours in the market, even if they were not quite so fast as alizarine.

Notes.

PUBLIC WORKS IN GREECE.

The original contractors for the cutting of the Corinth Canal have, according to the British Consul at Patras, ceded to the Comptoir d' Escompte, of Paris, their contract. The new company were to commence operations in January last. The difficulty in completing the work arose from the discovery of a bed of rock which will cause a long delay. The railway between Athens and Patras has been completed, and another line is to be commenced between Patras and Pirgos.

THE NICARAGUAN CANAL.

The delays in the construction of the Panama Canal, and the enormous sums of money which have already been expended on the work which has so far been carried out, have caused most people out of France to arrive at the conclusion that M. de Lesseps' scheme will ultimately break down. For years past, occasional paragraphs have also been seen in connection with the Nicaraguan Canal; but, according to Mr. M. Vaughan, the British Consul at Granada, Nicaragua, the general opinion there is that no serious work will be done. However, the contract between the Nicaraguan Government and Mr. A. G. Menocal, the representative of the Nicaraguan Canal Association in New York, which was signed last April, stipulates for the forfeiture of £20,000 if work is not begun within a certain time, and this money was duly deposited with the Government.

NATIVE INDUSTRIES IN ROUMANIA.

In order to stimulate native industries in Roumania, the Government of that country has decided to afford special privileges to persons possessed of a capital of £2,000 who are willing to establish factories to employ not fewer than twenty-five hands. Land will be given free for a period of ninety years, there will be freedom from taxation for fifteen years, free admission of machinery and of raw materials used in the manufacture of the latter which cannot be obtained in sufficient quantities in the country. All articles imported, which are re-exported after being worked up in the country, will be entitled to a drawback equal to the duties paid on their importation. Manufacturers working under this law must employ technical processes and improved machinery, under the charge of experienced foremen. The Government will give the preference in its contracts to articles of home manufacture.

ROYAL METEOROLOGICAL SOCIETY.

At the monthly meeting of this Society, held on the 15th ult., a paper was read on "Electrical and Meteorological Observations on the Peak of Teneriffe," by the Hon. Ralph Abercromby, F.R.Met.Soc. The author made a trip to the Island of Teneriffe, in October, 1887, for the purpose of making some electrical and meteorological observations, and found the electrical condition of the Peak of Teneriffe to be the same as that in other parts of the world. The potential was, even at considerable altitudes, moderately positive, from 100 volts to 150 volts, at 5ft. 5in. from the ground; but it rose to 549 volts on the summit of the Peak (12,200ft.) and to 247 volts on the top of the rock of Gayga (7100ft.). A large number of halos were seen associated with local showers and cloud masses. The necessary ice dust appeared to be formed by rising currents. The shadow of the Peak was seen projected against the sky at sunset. The idea of a south-west current flowing directly over the north-east trade was found to be erroneous. There was always a regular vertical succession of air currents, in intermediate directions at different levels, from the surface upwards, so that the air was always circulating on a complicated screw system. Papers were also read on the "Rainfall of South Africa, 1842-1886," by Mr. W. B. Tripp, M.Inst.C.E., F.R.Met.Soc., and on "Some Methods of Cloud Measurements," by Mr. Nils Ekholm.

CANADIAN RAILWAYS.

A favourable report of the progress which is being made by Canada in railway construction has been given by Mr. J. G. Colmer, in the course of a paper delivered before the Royal Statistical Society. Since the confederation in 1867, the railway mileage of Canada has extended from 2258 to nearly 12,000 miles; the population in the same time increasing from 3,400,000 to nearly 5,000,000. Although many hundreds of miles of railway constructed since 1880 run through districts which are very thinly inhabited, and which have not much effect on the traffic returns at present, yet since 1877 the passenger traffic has increased 50 per cent., the goods traffic 130 per cent., and the earnings 83 per cent., while the working expenses are 60 per cent. higher. Out of a capital of about £135,000,000 expended on Canadian railways, £32,000,000 has been contributed by the Dominion and Provincial Governments and by local municipalities.

INTERNATIONAL GEOLOGICAL CONGRESS.

The triennial meeting of the geologists of the world is to be held this year in London, during the third week in September. This Association was founded in America in 1876, at the Buffalo meeting of the American Association for the Achievement of Science, with the object of providing an opportunity for matters of geological interest and importance to be discussed by geologists of all nationalities. The succeeding meetings were held at Paris, Bologna, and Paris, and have been well attended. On the Continent, the several Governments have rendered great assistance to the Executive Committees by giving additional facilities to members visiting the meeting on the different State railways and in other official ways which are not possible in England. The funds necessary to insure the success of the meeting are being raised by private contributions, and the committee, which is a large and representative one, are confident that the present meeting will be a successful one. Many matters of general interest and problems related to the economic applications of geological science, mining, and metallurgy will be brought before the meeting, and the discussions which are likely to take place will afford a valuable contribution to our knowledge of these subjects. Professor J. Prestwich has been elected the president for the meeting, and the presidents of several of the London and local societies of allied sciences and mining associations are rendering their assistance to the committee. Mr. Topley and Mr. Hulke are acting as the general secretaries of the Congress; and the geologists of this country intend to offer their *confrères* from the Continent and America a hearty welcome to this country. A series of excursions are being planned to take place in the week preceding the meeting, which should prove an additional attraction to those visiting London and the neighbourhood for the first time and interested in its geology.

COLONIAL CONTRACTS.

Strong expressions of dissatisfaction have recently been given by some of the leading Chambers of Commerce on the subject of contracts for Colonial Governments, and has been brought prominently to the front through the action of the Government of New South Wales in connection with a contract for locomotives. It seems that forty-four of these were wanted, and tenders were asked for in the spring of last year from some of the leading makers in the Colonies, Europe, and America. A large number of quotations were furnished, and considerable expense was incurred by the makers in the preparation of specifications, in the belief that the work would be adjudicated on fair business principles. It was found that the lowest estimate had been sent in by Messrs. Nielson & Co., of Glasgow, and that the Colonial tenderers had quoted much higher figures, in some cases over 50 per cent. more than the British makers. But the Colonial Government has thrown all the offers aside, and practically told the Colonial firms that they desired to give them the orders, but that their prices were too high, and asked them to re-tender. This they have done, but the prices named are still very much higher than those of the British firms. Nothing has yet been settled about the order, but manufacturers ought to protest vigorously against such treatment as that to which the locomotive makers have been subjected. It is quite evident, from a heated controversy which the transaction has provoked in Sydney, that the only object in asking British makers to send in tenders was to check the prices of the Colonial competitors, as the Minister of Public Works has indicated that rather than allow the work to go out of the country, he will have the engines built at a Government repairing shop, in which it would be quite impossible to turn them out in a satisfactory manner, either as regards price or quality. If the Colonies are determined to protect their industries, of course we cannot prevent them; but our manufacturers should at least take steps to show them that they object to be used as mere conveniences.

OUR TRADE WITH JAPAN.

In the *Handelsmuseum*, which is issued from the Oriental Museum in Vienna, there lately appeared an article on the foreign trade of Japan, which contains a considerable amount of interesting matter. Great Britain still takes the first place in that trade; but since 1880 her share has steadily declined, especially as regards the import of goods. In millions of yen, the imports of British goods amounted, in 1877, to 15·7, in 1878 to 19·2, in 1879 to 16·8, in 1880 to 19·6, in 1881 to 16·4, in 1882 to 14, in 1883 to 12·7, in 1884 to 12·7, in 1885 to 12·4, and in 1886 to 12·7 million yen. Britain's participation amounted in 1878 to 58·6 per cent., in 1885 to 42·3 per cent., and in 1886 to 39·5 per cent. of the total imports of these years, and has thus since 1878 decreased by 19·1 per cent. Germany takes the second place on the list with 7·2 per cent. of the imports, and has since 1883 outrun France. The reasons given for this by the *Handelsmuseum* are very similar to those which we have indicated on various occasions. The British merchants ignored, up till lately, the existence of their competitors. They sat in their offices and expected their customers to call upon them, and they seemed to pay little attention to the demands or wishes of those who bought their goods. The German merchants go very differently to work. They generally begin by learning the Japanese language, and thus they are able to bring themselves more into direct contact with the people, or with Japanese agents. They do not neglect the smallest order, and they do all in their power to satisfy the wishes of the buyers; and lastly, they generally offer more advantageous terms than the British merchants. Moreover, the quality of certain British goods has deteriorated during recent years, and the Japanese Chamber of Commerce at Tokio, some time ago, did not hesitate to state that the quality of English cotton goods is deteriorating from year to year. Our contemporary concludes its article by saying that better, or at least equal quality at cheaper prices, prompt delivery exactly according to sample, perseverance, and tenacity are the advantages which Germans offer to the Japanese merchants, and to which their success is due. We commend its remarks to the attention of British merchants.

TRAIN LIGHTING IN GERMANY.

At a recent meeting of the Frankfort branch of the Society of German Engineers, Herr Voigt gave some interesting figures regarding the cost of train lighting on various German railways. On the Würtemberg lines electric lighting has now been in use for some time, and the cost per hour for a $12\frac{1}{2}$ c.p. lamp, based on the use of the light for 2100 hours per annum, varies from ·31d. to ·44d., the average being considerably below the cost of lighting by oil gas. The cost of oil gas is least on the State railway in Saxony, the lamp-hour costing there ·376d., and most on the Halberstadt and Blankenburg line, where the cost per lamp-hour amounts to ·69d. The cost of gas plant, including compressing machinery and piping, amounts to £2,500 for an output sufficient to supply 150 carriages with gas. The advantages of electric train lighting are summarised as follow: (1) Complete independence of the charging station, so that the electrically lighted trains may be run over any lines. With oil gas the whole service is disorganised if through an accident at the gas works or through fire the supply of gas is interrupted; (2) the light is better than gas, and there is no danger of explosion and fire in case of collision; (3) the expenses for labour are lower, because no preparations are required before the light is actually wanted; (4) the working expenses are lower, as found by experience; (5) the cost of plant is only slightly greater than that for gas lighting; (6) the weight of lighting plant to be carried on the train is less than with gas. It is interesting to note that an engineering works in Esslingen have already fitted several trains not only in Germany, but also abroad, with electric lighting plant. Amongst these are six trains on the Novara-Seregno line in Italy, and some on the Russian South-Western Railway. On the Italian lines the plant works almost automatically, an attendant only accompanying the train over a few stations to oil and look after the machinery, and then returns by the next train in the opposite direction, so that during most of the time the machinery is left to itself. Notwithstanding this want of supervision no hitch has as yet occurred in the lighting.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

17th February, 1888.

2381. Hall, J. H. ..... Boiler furnaces.
2384. Mills, J. ..... Steam boilers.
2387. Pinnington, G. ..... Rotary engines.
2389. Hamilton, T. B. ..... Pickers for looms.
2393. Pickles, G. ..... Machinery for planing wood.
2395. Appleyard, J. ..... Ironing machines.
2396. Whitby, J. ..... Manufacture of gloves.
2398. Huck, G. ..... Looms.
2399. Edwards, S. ..... Lawn mowing machines.
2400. Stacey & Wilkinson ... Apparatus for pumping.
2401. Crowther, J. ..... Pistons.
2402. Simpson, W. F. ..... Furnace for steam boilers.
2403. Norman & Norman ..... Grinding mill.
2409. Kendall & Cooper ..... Railway signalling.
2413. Miles, A. ..... Broughams.
2418. Williams, H. A. ..... Shaping metal rods.
2419. Fournier, G. ..... Manufacture of hats.
2423. Morgan, C. H. ..... Manufacture of rolled wire.
2424. Morgan, C. H. ..... Wire rod reeling machines.

18th February, 1888.

2430. Dudgeon & Thompson.. Shuttles for looms.
2432. Stoney, F. G. M. ..... Grabs for excavating.
2441. Midgley, J. W. ..... Tension device for spinning machines.
2442. Begg, W. ..... Furnace for the prevention of smoke.
2443. Hawke, J. ..... Harrows.
2444. Rariden & Heath ..... Car couplings.
2446. Elcoate, T. ..... Valves for steam engines.
2453. Henderson, A. C. ..... Boot making (*Robert*).
2462. Williams, T. H. ..... Manufacture of bottles.
2466. Quack, E. ..... Gas engines.
2467. Cole, T. W. ..... Steam engines.
2468. Stevens & Stevens. ... Harrows.
2472. Clark, A. M. ..... An improved motor (*Honigmann*).
2473. Schotte, A. ..... Looms.

20th February, 1888.

2478. Wilding, R. ..... Spinning machines.
2489. Walker, J. ..... Lathes.
2498. Michaelis & Smethurst ..... Gig mills.
2500. Brigg, T. H. ..... Looms.
2504. Goodwin, G. ..... Machinery for grading grain.
2518. Lansell, G. ..... Boiler flues.
2528. Wallace, J. ..... Machinery for preparing flax.
2532. Singer & Judell ..... Cleansing wool.

21st February, 1888.

2535. Marchington, W. E. ... Spinning machines.
2536. Alley, S. ..... Screw propellers.
2537. Gass & Gass ..... Revolving cloth stretchers.
2542. Ross, J. H. ..... Compressed air motor.
2545. Taylor, J. A. ..... Scutching machines.
2550. Christie, W. ..... Stopping the progress of vessels.
2555. Annand, R. C. ..... Printing machines.
2560. Grout & Bowers ..... Sewing machines.
2561. Tilton, H. W. ..... Sewing machinery (*Angell*).
2565. Harris, E. J. ..... Puddling furnaces.
2569. Sauvee, A. ..... Armoured turret (*Canet*).
2571. Boult, A. J. ..... Car couplings (*Brown*).
2572. Thompson, W. P. ..... Air compressors (*Reynolds*).
2573. Boult, A. J. ..... Knitting machines (*Clay*).
2579. Lake, H. H. ..... Button hole machines (*Wheeler*).
2580. Lake, H. H. ..... Gun carriages (*Hill*).
2583. Lindley, L. ..... Sewing machines.
2585. McInnes, A. ..... Boiler furnaces.
2589. Harriss-Gastrell, J. P. ..... Compound engines.
2590. Sterry & Sterry ..... Gas engines.
2598. Hodgson, A. ..... Car couplings.
2604. Nordenfelt, T. ..... Breech mechanism for guns.
2607. Dobbs, C. J. ..... Annealing kilns for slag blocks.
2610. Lejeune, A. ..... Carding machines.

22nd February, 1888.

2616. Fairburn & Casson ... Shuttles of looms.
2617. Donkin & Nichol ..... Water tight doors for bulkheads of ships.
2622. Ford, W. ..... Breech loading fire arms.
2633. McGhie, J. ..... Manufacture of metal tubes.
2640. Miller, J. N. ..... Rotary engines.
2642. Walker, J. C. ..... Washing machines.
2643. Walker, J. C. ..... Combing machines.
2644. Rhodes, S. G. ..... Weighing machine.
2652. Thorneycroft, T. ..... Carriages.
2658. Hudson & Hudson ... Looms.
2659. Stott, J. ..... Boring vertical holes for mining purposes.
2668. Jones, J. G. ..... Governing steam engines.
2669. Gerdes, H. ..... Manufacture of carding teeth and cloth.
2671. Holmes, C. D. ..... Corrugated tubes.
2672. Hornsby & Ogle ..... Pulverising minerals.
2677. Lang & Jeffries ..... Drop-down small arms.

23rd February, 1888.

2680. Williamson, T. ..... Hot bloom shears.
2683. Douglas & Douglas ... Manufacture of boots.
2688. Rankine, J. ..... Cast plates for boilers.
2693. Halliwell, J. ..... Connecting together sheets of metal.
2696. Brown, A. B. ..... Steam engines.
2699. Barstow & Saaw ..... Combing machines.

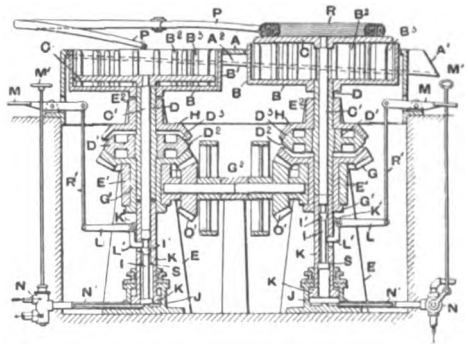
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.



Compiled from the Published Specifications by W. E. HEYS, 70, *Market-street, Manchester.*

ENGINEERING.

TAKING UP MOTION FOR LOOMS.—*J. Cowburn & C. Peck, Eccles, Lancashire.*—This invention consists of arrangements by means of which the face of the cloth is prevented from being acted on by the taking up rollers. The axle of the taking up roller is mounted on arms, and rotation is imparted to it in a similar manner to that described in Patent No. 5896 of 1884, granted to the same inventors. The cloth is passed partially round a bar or guide, and then partially round the taking up roller, which is placed in front of the cloth roller. In another method described in the specification the invention is carried into effect by placing the taking up roller in front of or below the cloth roller, and the cloth is conducted from the breast beam of the loom to the taking up roller. The latter roller thus acts in both cases on the back of the cloth, and injury to the face is thereby avoided. There are two claims, one for each method.—No. 4117. March 18th, 1887. 8*d.*

PRODUCTION OF IRON.—*G. G. Mullins, St. Louis, U.S.A.*—Silica in the form of very pure quartz is added to the iron after having been ground to a fine powder. The fused silica has a strong affinity for sulphur and phosphorus, which it is so necessary to remove from iron. In carrying out the process embodied in this invention a puddling furnace is charged with ores or with pig iron. After this metal has been reduced to a molten state and brought to the highest white heat possible, a quantity of the powdered silica is added, amounting to from five to twenty-five per cent. of the weight of the iron, according to its quality. The mass is thoroughly puddled and allowed to boil for a few minutes, until certain blue and greenish flames are emitted from the boiling mass. The metal is then worked out in the usual manner. The sulphates and phosphates are removed with the scoria, and the silica remaining tends to strengthen the iron in the usual way. The inventor makes one claim for the above purifying process.—No. 12741. September 20th, 1887. 4*d.*

COILING MECHANISM FOR ROLLING MILLS.—*P. M. Justice, London.* (*F. H. Daniels, Worcester, Massachusetts, U.S.A.*)—The reeling apparatus, constructed according to this invention, is shown in vertical section in the accompanying diagram. Two reels B are supported on hollow shafts D, and are arranged so as to be level with the upper surface of the frame A. These reels are used alternately, and thus there is a continuous reeling action going on. A number of ribs B^3 project from the inner periphery B^1, and an equal number of vertical fingers B^3 rise up from the floor of the reels. The movable bottoms C consist of radial arms which fit between the ribs B^3. The floors C are supported on pillars C^1. The reels are rotated by means of the pulleys G^2, and the motion is transmitted through the gears O and the friction clutch D^1. The raising and lowering of the reels and movable bottoms is effected by the hydraulic mechanism I J K. The valve N is controlled at M^1 and supplies the water to the cylinder J. The plunger K is in contact with the shaft D, and the inner plunger I abuts against C^1. The lug I^1 and the

catch L^1 prevent the upward travel of I when necessary, and the shoulder S limits the height to which I can ascend. The action of the mechanism will now be described. If the pressure in the cylinder J is relieved, the plungers I and K descend and allow the friction clutch wheel D^1 to rest in contact with the rim of the gear G, as indicated on the left hand side of the figure. Rotary motion is thus imparted to B. The rod to be coiled is propelled by the finishing roll of the rolling mill, and is led to B through the guide pipe P and deposited upon the supporter C within the annular space between the ribs B^3 and the fingers B^3. It is there formed into coils by the rotation of the receptacle. Pressure is then admitted into J, and the plunger K is elevated together with the shaft D. The friction wheel D^1 is forced away from the gear G and into contact with the stationary rim H, as indicated at the right of the figure, and the rotation is thus stopped. The guide pipe P is in the meantime swung back into line with the trough A^1. The lever M is then operated so as to withdraw the catch L^1 from the lug I^1, and the pressure on I forces up the shaft C^1 and the supporter C. The coil of wire is thus lifted out of the receptacle. The inventor makes eleven claims, for the construction of the reel, for the combination of the mechanism for rotating and elevating it, for the application of the friction clutch, and for the locking lever L.—No. 2876. February 24th, 1887. 8*d.*

MACHINE FOR BRUSHING YARNS AND FABRICS.—*C. Binns, Manchester.*—A large central revolving brush is fixed in bearings in the frame of the machine, and round part of the brush are placed adjustable guiding rollers. The yarns or fabrics are carried over these rollers, and come in contact with the brushing sections of the large roller. Four small revolving brushes also move in bearings in the frame, and are parallel with the large brush. They rest in adjustable sockets in their bearings, so that they can be brought near to the fabric or lifted away from it at will. The material treated can thus be brushed on both sides at once. There is one claim for the improvement described.—No. 4799. March 31st, 1887. 8*d.*

GAS ENGINES.—*S. Griffin, Bath.*—In most gas engines the explosive compound, after having been ignited and expanded in the cylinder, is released at a pressure of 30lb. to 40lb. above the atmosphere, and consequently some available power is lost. In order to remedy this defect the inventor employs a cylinder and ports similar to those described in Patent No. 4080 of 1883, whereby the charge is introduced through a port close to the piston when at its full instroke, while the exhaust port is situated at the extreme end of the compression space furthest from the piston. According to the present invention, the compression space is made of a cubical content considerably less in proportion to the cubical contents of the sweep of the motor piston than has hitherto been usual. The cycle of operations employed may be similar to that described in the above mentioned patent, or may be the double cycle. In the former case, during one outstroke of the piston, air will be drawn into the cylinder, and gas may also be admitted during the first half of this stroke. At the next instroke the exhaust valve is open, and a portion of the air will pass through the exhaust valve, carrying with it the products of the previous combustion. During the whole of the next outstroke the air and gas is drawn into the cylinder. During the first portion of the next instroke the exhaust valve is again open for a sufficient time to allow the whole or any required portion of the air contained in the compression space in front of the explosive charge to be driven out. The exhaust valve is now closed, and the remaining part of the stroke compresses the charge. About the commencement of the next outstroke the charge is ignited, and it is expanded during the remainder of the stroke. During the next instroke a portion of the products of combustion equal to the sweep of

Digitized by Google

the piston is expelled, leaving only that contained in the clearance. The cycle is now completed. The inventor makes three claims for this improved method of introducing the gas.—No. 3934. March 15th, 1887. 8*d*.

HYDRAULIC CRANES FOR SHIPS.—*A. B. Brown, Edinburgh.*—This invention relates to certain improvements in the arrangements for slewing the crane jib, described in the specification of Patent No. 16939 of 1884, granted to the same patentee. A hydraulic cylinder for working the hoisting chain is placed between the two girders of the jib, and on the outer side of each girder is placed a long hydraulic cylinder of small diameter. Round the pulleys at the ends of the rams are passed chains which have one end fixed to the jib. The other ends go round a pulley on a stud fixed to the jib, and then round a pulley on a

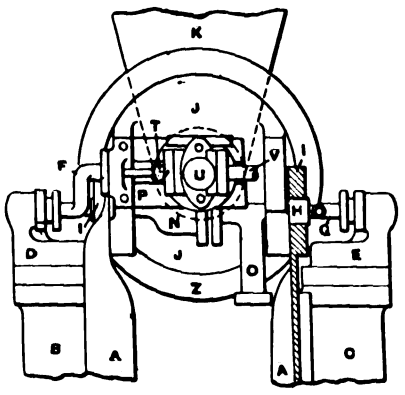


FIG. 1.

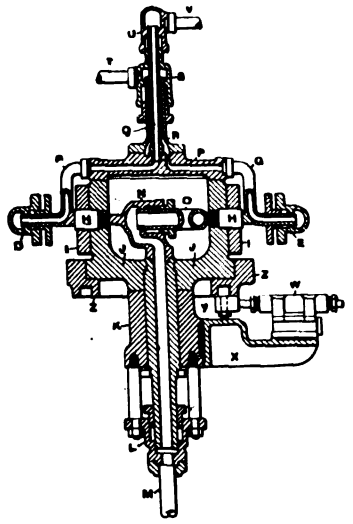
block which can be adjusted to any part of the jib. From the last mentioned pulley the chain is led to a fixed point at the side of the ship, and by making the hydraulic ram act on it the crane can be slewed. The two cylinders may be used for slewing in opposite directions; but with a raking mast only one cylinder is required for slewing, and the other is used for topping; the chain acted on by the latter is led to a pulley at the outer end of the jib, and thence up to a fixed point on the mast. The arrangement of pipes for leading the water to the slewing cylinders is shown in Figs. 1 and 2. Fig. 1 is a sectional plan of the inner end of the jib, and Fig. 2 is a vertical section of the same. The slewing cylinders B C are placed on the side of the girders A, and the blocks D E are fixed to their ends and communicate with them internally. The pipes F G have the same axis as the trunnions H, on which the joint eyes I of the girders A are jointed. The trunnions are fixed into the sides of the centre block J, which can turn about a vertical axis in the



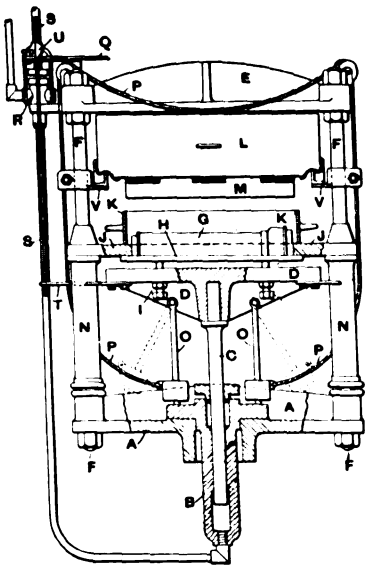


FIG. 2.

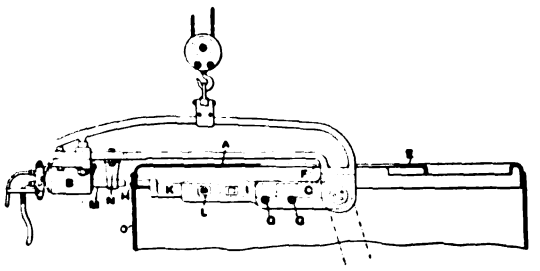
bracket K. The block J is also connected to a pipe M by which the water passes to and from the main jib cylinder. The stuffing box N is entered by a bent pipe O, which has its other end connected to the main cylinder. The pipes F G also communicate with passages in a piece P; one of these passages leads to a pipe Q and the other to a pipe R. The outer pipe R fits in a box S to which the pipe T is connected, and the inner pipe P passes up through S and leads to V. The box S is fixed to an upper bracket on the mast. If the cylinder B is arranged for slewing, the pipe T is led to a position near the hatchway where it is provided with a valve which controls the movements of the crane. If the cylinder C is arranged for topping, the pipe V is connected with a valve box W which is fixed to the bracket X; the valve rod Y is acted on by a grooved cam shown in section at Z fixed to the centre block J. When the jib is slewed inboard, the cam Z, acting on the valve rod Y, moves the valve in the box X so as to cause the jib to be raised. If found convenient the slewing action may be made automatic instead of the topping action. The inventor makes five claims, for the arrangement of the jib and pulleys, for the valve action of the slewing cylinders, and for the automatic motion provided by the cam.—No. 3112. March 1st, 1887. 8*d*.

WARP LACE MACHINES.—*J. Woolley, Nottingham.*—This invention introduces improvements in warp lace machines in which perforated steel bars and a guide bar carrying the pillar threads work in combination with a latch needle bar. Instead of the solid points working over or under the bars, and taking the threads from the steel bars and delivering them to the hooks, the inventor makes use of a double point or sheath formed out of thin sheet metal. Half its width is folded over on to its other half, so that the two sides lie parallel with each other, thus forming a double point or sheath. The doubled points enter the threads close under or close above the perforated steel bars, according to the construction of the machine, and convey the traversed fancy threads to the hooks. The hooks enter the double points, and in passing through them gather the whole of the threads from them, and place them on the reverse side of the needle to that on which the latch is turned. The hooks coming within the double points insure the delivery of the threads to the needles, and a greater number of top or bottom steel bars carrying the threads can be used. The combined movements of the hook bar and the bar carrying the double points are effected by links and truck bearing levers operated by cams on the cam shaft. The inventor makes one claim for the employment of double points working in conjunction with the hooks in warp lace machines, as described.—No. 5672. April 19th, 1887. 8*d*.

APPARATUS FOR MAKING MOULDS FOR CASTING.—*T. Alley and J. A. McLellan, Polmadie, Renfrew.*—In carrying out this invention a hydraulic press is used, with its cylinder at the base, and with a platen mounted upon the upper end of the plunger. The annexed diagram illustrates the arrangement and mode of operation, when applied to mould a pipe length. The flask or mould box for one half of the pipe is moulded at each operation of the machine. The hydraulic cylinder B is fixed to the base plate A, and the ram C carries the table D. The pattern G is placed on a plate H, which can be accurately adjusted and levelled by the screws I. When in position to receive the sand, the plate H is raised by the ram up to the parting plate J, through an opening in which the pattern

projects, so that one half of it is above the upper surface of the parting plate. The flask K is then placed on J, and the necessary quantity of sand is filled into it from the hopper L. The hopper is formed with a flat bottom, in two halves M hinged to its lower edges. After the sand has been run into the flask the ram is raised, carrying with it the platen, pattern, and parting plate up against the under side of the closed hopper bottom. The speed of lifting is such as to bring the sand, which projects up in a ridge along the middle of the flask, into contact with the hopper bottom, and the sand is thus made to apply itself compactly in contact with all parts of the pattern. The ram is then lowered, and the parting plate is guided by the columns F, on which it slides until the legs N reach some stops on the base plate. The descent of the platen D carrying the pattern is for a moment arrested when the parting plate is stopped, but immediately afterwards it descends to a distance sufficient to lower the pattern through the hole in the parting plate. The flask with the moulded sand in it is then removed, and an empty flask may be substituted for the next operation. For the purpose of temporarily arresting the descent of the platen, two weighted legs O are jointed to its under side. These legs encounter the top flange of the hydraulic cylinder, but are, a moment later, drawn away by ropes P. The movements of the apparatus are controlled by a hand lever Q, connected to the valve box R, through which the supply of water passes. The speeds of the various parts are controlled automatically by a rod S, which is adjustably fixed to a bracket T fixed to the platen. This rod is formed with a cam surface U at its upper end, which, when the hand lever Q is turned to put the cylinder in communication with the exhaust, at first prevents the exhaust being fully opened, but allows it to be so when the ram has descended a certain distance. The inventors make four claims, for the sand supplier, for the arrangement of the platen and parting plate, and for the speed controller described.—No. 3294. March 4th, 1887. 8*d*.



REAPING MACHINES.—*G. P. Cooper, Elton, Yorkshire.*—The inventor dispenses with the bevel gear and crank which usually supply the oscillating motion to the knives, and substitutes for them a drum which has an eccentric slot round its curved surface. A pin sliding in this slot is connected to a lever which is also connected at its other end with the cutter bar. The oscillating movement which the irregular slot gives to the pin causes the required reciprocation of the knives. The inventor makes one claim for this combination.—No. 11455. August 23rd, 1887. 6*d*.

SLATE WORKING MACHINERY.—*T. E. Morris, Carnarvon.*—The object of this invention is to construct the bearings and gear of a slate working machine in such a manner as to protect them from the dust which is formed in the operation of sawing. A worm is fixed to the saw spindle, and is enclosed in a metal box. A spindle at right angles to the saw spindle transmits motion to another shaft parallel to the saw spindle, by means of another worm gear. The whole of this mechanism is enclosed in a box containing a lubricant. On the shaft parallel to the saw spindle are clutch jaws and a pinion, which gears with a rack on the sawing table. The table is carried by means of two iron rollers, which are journalled in the casing of the machine. The inventor makes four claims.—No. 12900. September 23rd, 1887. 8*d*.

ROLLING THIN SHEETS OF IRON AND STEEL.—*J. Lysaght, Bristol, and W. R. Lysaght, Wolverhampton.*—This invention consists of rolling thin sheets between sheets of thicker gauge; the three sheets together are passed through rollers. The advantage of this method is that any inequality in rolling will be distributed equally among the sheets, and consequently the thin sheet will have a very small proportion of the irregularity. The inventors specify several methods of carrying out this idea, but do not limit themselves to any one; and they claim: rolling very thin gauges of iron and steel sheets between sheets of thicker gauge, for the purpose set forth.—No. 4191. March 21st, 1887. 6*d*.

PUNCHING HOLES IN METAL PLATES.—*H. T. Shaw & C. Chittick, London.*—The plate in which the holes are to be punched is supported on horizontal rollers. Along one side of the supports is a long table, which is also mounted on rollers, so that it may be moved endwise. At each end of the table is a saddle projecting from that side of the table at which the punch works. The saddles are capable of being moved along the table so that they may be brought against the ends of the plate and clamped to the table. The table and the plate then move together. The step by step movement of the table is brought about by having a number of pegs projecting from the side of the table. These pegs are acted on in succession by a revolving cam, the axis of which is parallel to the length of the table. The cam is formed of a cylindrical boss, with a fin projecting from it in the form of a screw round part of its circumference. The rotation of this cam moves the peg on, and with it the table. A second fin projects from the circumference, and holds the pegs between it and the first fin. There is provision made for varying the distance apart of the pegs, according to the number of holes to be punched in the plate. A longitudinal slot is made in the side of the table, and the pegs are screwed into the slot at the required distance apart. The inventors make three claims for the apparatus for giving the step by step motion, for the adjustable pegs, and for the general construction of the machine.—No. 2744. February 22nd, 1887. 8*d*.

PUNCHING AND RIVETING MACHINES.—*R. H. Tweddell, London; J. Platt & J. Fielding, Gloucester.*—This machine is arranged so that the hydraulic ram and the abutting tool shall be applicable for punching and riveting at the angles of boilers, and at similar parts of other structures where the ordinary machines are useless. The accompanying diagram shows the method of arrangement pursued by the inventors. The girder A carries at one end the hydraulic cylinder B, the plunger projecting from which carries the tool M. The abutment arm I is jointed to the other end of the girder between the two cheeks C. The abutting tool K can be adjusted longitudinally in the arm I, and is secured in its position by a cotter L. In the shell D E of the boiler to be riveted is a hole F, through which the arm I can be

passed when it is turned on its joint to a position such as is indicated by the dotted lines. After insertion, the arm I is secured in its position by the bolts G, and the tool K carried by it serves as an abutment when the tool M advances to punch a hole, or to head a rivet H. The inventors claim the construction of a hydraulic punching and riveting machine, wherein the cylinder with the tool is fixed at one end of a girder, and an abutment arm is jointed to the other end of the girder in such a manner that the arm, when turned in one position, can be introduced through a hole in the shell of the boiler, and can then be turned so as to present its abutment tool inside in a line with the punching or riveting tool.—No. 2828. February 23rd, 1887. 8*d*.

ROTARY ENGINE.—*T. Lambert, Plymouth.*—Two cylinders are mounted on the same axis, with a hollow dividing piece fixed between their ends. The dividing piece is bored to the same width as the crank disc, which works in contact with it. On the outer ends of the cylinders are cast covers, with central rings on them. The crank disc is formed with a cylindrical ring cast on each side, and working in contact with the faces of the cylinder covers. These rings are mounted eccentrically to the centre of the cylinders, and the disc divides the cylinders into two chambers, the inner chamber comprised within the eccentric ring and the discs on the cylinder covers, and the outer chamber constituted by the space between the outside of the eccentric rings and the bore of the cylinder. The pistons are common to both chambers, and are recessed for slides, which work loosely round the pins on the faces of the crank disc. The eccentric rings are slotted to correspond. The steam is admitted to the inner chambers through ports in the cylinder covers, and acts on one side of the pistons. These pistons consequently move round together with the crank disc and rings. The usual cut-off and expansion then takes place, and at a further point in the revolution the steam is allowed to pass to the outer chambers, where it again acts on the pistons. There are two main ports to each inner chamber, and two ports connecting the inner and outer chambers. Rotary valves are used to control the action of the ports. The inventor makes six claims, for the two cylinders and crank disc having eccentric rings, for the loose piston, for the rotary valves, and for the general construction of the machine.—No. 4343. March 23rd, 1887. 8*d*.

MAGAZINE FOR FIRE ARMS.—*P. Mauser, Oberndorf, Württemberg.*—This invention relates to a cartridge box or magazine, which may be attached to and detached from the breech piece of breech loading fire arms. In Figs. 1 and 2 are shown elevations of the two sides of the magazine in conjunction with the Mauser gun. The magazine consists of a box A, in which the cartridges are confined by the spring J^1. The box is fixed to the chamber of the breech piece C by the frame work T, between which and the

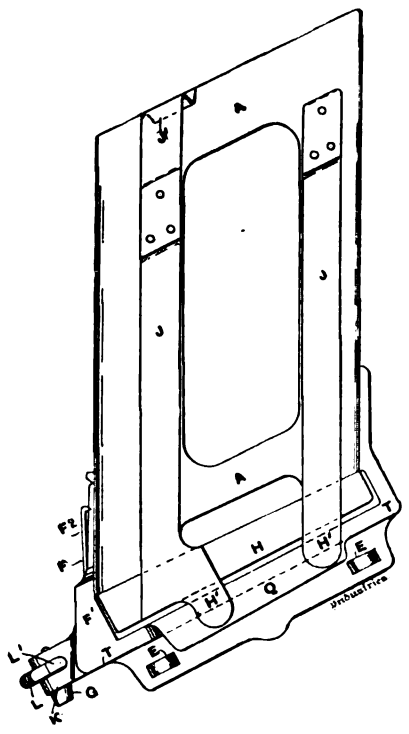

FIG. 1.

box is the carrier frame H. The carrier is attached to the springs J, and can be moved forwards in Fig. 1 to allow the cartridges to drop out one by one into the chamber C. The springs J extend downwards at H^1 in order to guide the cartridges in their journey to the chamber C, and the springs J tend to return the carrier to its normal position. Upon the outside of the rear wall of the box A is fastened a guide F^1 for the slide block F. The block F carries an angle lever L in such a manner that it swings horizontally round a pin secured to the foot K. In its normal position the longer arm of the lever touches

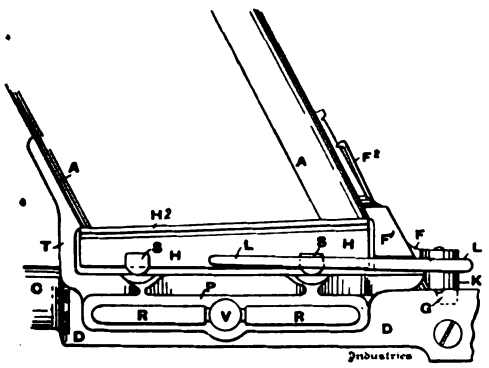

FIG. 2.

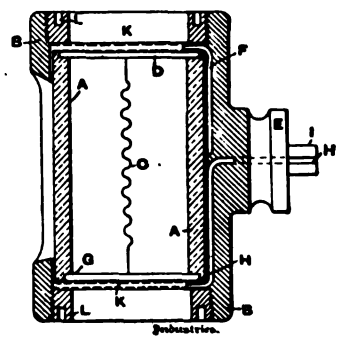
the wall of the carrier shown in Fig. 2. The shorter arm L^1 protrudes beyond the foot K to the front of Fig. 1, so far as to be acted on by a nose of the locking bolt. The attachment of the magazine to the breech piece is simple. The bottom of the frame T is formed with two ribs or flanges P and Q, by means of which it is set astride upon the left wall of the chamber C. Two spring studs E attached to the rib P enter the wall and secure the magazine in this position. These studs extend from the longer arms of the levers R, which turn round pins in the flange P. The shorter arms of these levers work in an annular groove in the push piece V. A coiled spring tends to press this piece outwards, therefore the studs E are constantly pressed on the wall of the chamber C. By pressing the piece B inwards, the studs E are withdrawn, and the magazine may be removed. There are modifications in the manner of attaching the magazine to the gun described in the specification. The inventor makes nine claims for the magazine and for its method of attachment.—No. 16274. November 26th, 1887. 8*d*.

PISTONS.—*G. W. McQuaker, Dalry, Ayr.*—The piston designed by the inventor has two L shaped outer packing rings, which are placed together so as to form a ring with an annular channel on its inside. The inner rim of the channel is turned at an angle with the plane of the ring, and on this slanting side of the rim another ring presses. The circumference of this pressing ring is made of three different segments, and the segments are made to press outwards on the packing rings by coiled springs. These springs form chords of the circle of the rings, and each of the springs causes a mutual reaction between two of the segments. The inventor makes two claims for this arrangement of rings.—No. 4693. March 29th, 1887. 8*d*.



HEDDLES FOR LOOMS.—*W. R. Lake, London.* (*G. V. Morey, Boston, U.S.A.*)—In the construction of machine made heddles the inventor employs two continuous wire strands to connect the upper and lower heddle bars to all the eyes of a leaf of heddles. The continuous wire loops are prevented from slipping from their places on the top and bottom bars by means of a rubber or textile pad arranged in a groove on the bottom edge of the lower heddle bars. In addition, two metallic rods are arranged, one at each end of the heddle bars, and a thread and nut on each serves to tighten or loosen the wire loops by extending or contracting the distance between the heddle bars. The inventor makes two claims for the machine made heddle and for the method of constructing it.—No. 16132. November 23rd, 1887. 8*d*.

ELECTRICITY.

DYNAMOS.—*F. Bosshardt, Manchester.* (*A. L. H. Desbois, Angers, France.*)—The object of this invention is to regulate the strength of the currents automatically. To obtain the electric balance between the armature and the field magnets, the latter are to be rotated in a reverse direction to the former. Thus if one of them is accelerated, the other diminishes in velocity, and forms, therefore, an automatically governed balance. The electromagnets are turned at half the velocity of the armature. A differential movement is employed in the driving gear, consisting of two cones mounted side by side, one of them controlling the armature and the other the electromagnets. The cones are in contact with a friction pulley or a strap, the tendency of which is to move to the middle of the cones. The strap is brought into communication by means of a rod, either with a special regulator or with a galvanometer, and the swing imparted to the needle causes the strap to be displaced on the cones. The inventor makes one claim for the mode of revolution of the magnets and armature, and for the application of the cones in combination with the galvanometer.—No. 2419. February 16th, 1887. 8*d*.

ELECTRICAL TRANSFORMERS.—*J. G. Statter, West Drayton.*—In order to obtain the greatest possible inductive effect of the primary on the secondary coil in electrical transformers, the inventor makes use of ⊔ shaped pieces, stamped out of thin sheet iron. Two such pieces are insulated on one side of each, and the insulated parts are placed together and formed into a compound plate. Two coils, primary and secondary, rectangular in shape and in winding, are placed one on the top of the other, and bound together with insulating tape in such a way that the compound coil thus formed shall make a rectangle which will just fill up one of the spaces between the two upright projections of the plate. In order to construct the transformer, suppose that the workman holds the compound coil vertically upon its end. With his right hand he places a plate in position, inserting the central projection between the sides of the coil. With his left hand he forces in another plate in the opposite direction, and presses it upon the first plate. Then, with his right hand, he places another plate in the same direction as the first, and so on, alternately inserting plates from either side so that the projections of the plates overlap each other. The inventor makes three claims for this method of constructing the transformer.—No. 7530. May 25th, 1887. 8*d*.

DETECTION OF EXPLOSIVE GASES IN MINES.—*J. W. Swan, Bromley, Kent.*—The apparatus constructed according to this invention is intended for the detection of explosive gases in mines and other places. A chamber surrounds a platinum wire through which an electric current may be sent. The intensity of the glow of this wire affords a sufficient indication of the presence of combustible gases. One form of apparatus designed by the inventor is shown in sectional elevation in the accompanying figure. A is a glass tube, the open ends of which are covered

with discs of wire gauze K. The screwed rings L serve to keep the discs in position. In the tube A is a plantinum wire C attached at its opposite ends to the wires D G. The wires F H are in contact with D G, and are led through the vulcanite cover B to either side of the cylindrical boss I. The wire H is shown in the figure on the nearest side of I, while the wire F emerges from the cover on the side of I furthest away in the figure. Two parallel wires not shown in the figure press on either side of the boss I, and are connected at their other ends to the battery. By turning round the casing B, the emerging wires F H are brought into contact with the wires from the battery, and the platinum wire C is thus switched into the circuit. The current may thus be brought into the wire C, or cut off from it at will by simply turning the whole case. When the instrument is to be used, the tube is closed to the air by placing the finger and thumb against the openings at the ends. The brightness of the wire under these conditions is observed. Then the inside of the tube is left free to the air by the removal of the finger and thumb; the degree of luminosity of the wire indicates the presence of explosive gases, and to some extent the quantity of them. In another form of apparatus, two wires are placed side by side, one of them being permanently surrounded by a glass tube, so as to exclude the outside air, and the other exposed directly to the atmosphere, so that the comparison of their luminosities can be made in one observation. The inventor makes three claims.—No. 3362. March 4th, 1887. 8*d*.

ELECTRICAL PROPULSION OF VEHICLES.—*F. Wynne, London.*—This invention involves certain improvements and developments of former inventions by the same patentee. The carriage is propelled along the road by means of a motor in the vehicle itself. Plates or studs are employed in connection with a closed channel, in which is a main conductor of electricity. The connection of the main conductor with the road or positive contacts is by means of contact makers, each of which carries a suitable armature. The armature is attracted by the magnetic influence of the stud when polarised magnetically. When thus moved the armature makes and keeps electrical connection between the main conductor and the stud as long as the magnetisation of the stud continues. Each road contact is provided with its own contact maker, which works in a space between the lower end of the stud and the main conductor. These spaces may together form a continuous channel, in which the main conductor is carried; or they may be discontinuous spaces, the main conductor being left bare only in these spaces where the contact maker works. The contact maker is most conveniently a strip of copper, and is hinged on an extension of the lower end of the road contact; it is normally held out of contact with the said stud or main conductor respectively by its weight or by a spring, until forced into contact by the temporary magnetic influence. In one arrangement the lower part of the insulated positive contact of soft iron is wound with insulated wire, thus forming a solenoid of high resistance. One end of the insulated wire is connected to the metal of the stud, and the other with one of a second set of insulated earth contacts exposed in the roadway, and with which the vehicle in its passage makes contact. The electromagnet carried on the vehicle is in the form of a star, each ray of which is constituted an electromagnet by being wound with solenoids. The star revolves on an axis parallel to that of the axles of the vehicles. The inventor makes six claims for the combination of the two sets of contacts, and for the construction of the magnets and contacts.—No. 747. January 17th, 1887. 8*d*.

CHEMISTRY.

EXTRACTION OF ALUMINIUM.—*C. Netto, Dresden.*—The process of extraction of aluminium by means of the mutual action of cryolite and sodium is modified by some improvements embodied in this invention. The cryolite is first melted in a crucible together with a suitable proportion of decrepitated common salt. After a complete fusion has been effected, the sodium is introduced by a specially constructed instrument, and placed at the bottom of the crucible. The decomposition is rapid, and in the course of a few moments the whole molten mass must be cast into an iron mould. The aluminium sinks to the bottom in a single lump. The advantages of this method are that the short time allowed for decomposition precludes the possibility of injury to the crucible, that no sodium is burnt on the surface of the molten mass, and that the aluminium is precipitated to the bottom in a single piece instead of being scattered all through the mass. The instrument designed for placing the sodium under the surface of the fused cryolite consists of an iron rod, with a cap at one end, which has a number of perforations in it. Under the cap is a hook to which the piece of sodium is attached. The cap holds the sodium at the bottom of the crucible, but the perforations allow small pieces of it to ascend and combine with the cryolite. In order to prevent explosions, the sodium must be made free from oil by being cast *into* an iron mould, and protected from the air previously to its use in this process. The inventor makes four claims for the method of manufacture and for the instrument.—No. 4228. March 21st, 1887. 11*d*.

PYROSULPHATES OF THE ALKALI METALS.—*H. Baum, Mannheim, Germany.*—The inventor of the present process has discovered that when the hydrosulphates, or molecular mixtures of neutral sulphates and sulphuric acid, are subjected to a comparatively low temperature of 260°C. to 320°C., they break up into pyrosulphates, and liberate water without the formation of any anhydrous sulphuric acid. The mode of manufacture, according to this invention, is as follows: 240 parts of acid sulphate of sodium, or 142 parts of neutral sulphate, and 98 parts of hydrated sulphuric acid, at 66°Bé., are placed in a cast iron retort. The retort is connected with an air pump, and is heated during exhaustion to 260°C. After a fusion, lasting five to eight hours, the resulting mass is cast in plates. A stirring apparatus is introduced into the retort; and a condenser and receiver, connected by a glass tube, are placed between the retort and the air pump, in order that the time of completion of the process may be easily detected. This time is ascertained by the water disappearing from the glass tube. The inventor makes one claim for this process.—No. 4241. March 21st, 1887. 6*d*.

MONOHYDRATED SULPHURIC ACID.—*J. Brock, Widnes.* (*G. Lunge, Zurich.*)—According to this invention, commercial sulphuric acid is concentrated by evaporation in the usual way, until it assumes the form of rectified oil of vitriol. This acid, after having been cooled, is conveyed to a store tank, placed at a higher level than the charging box of the refrigerator. The charging box is made of iron, and is of such a shape that it stretches from side to side across the tank containing the freezing cells. It is divided by vertical partitions into as many divisions as there are freezing cells, and each division is of such a size that its contents, after being blown out, exactly fill one of the freezing cells to a suitable height. The partitions do not quite reach up to the top of the charging box, so that all the divisions may be filled by the supply pipe from the store tank, and their contents may be forced out at the same time by means of compressed air. The row of freezing cells is suspended in an iron frame, and is moved on a travelling crane. The space between two rows of cells is filled with a solution of chloride of calcium, kept at a low temperature. After having been exposed to the freezing tank, the row of cells is lifted out and dipped into warm water, in order to effect the removal of the frozen mass from the sides of the cells. The cells are then tilted out into a spout containing an Archimedean screw, which crushes the frozen mass, and conveys it to a centrifugal machine. In this machine the crystallised, monohydrated acid is separated out from the liquid. The solid mass is scooped out into another vessel, where it is melted and made ready for storage. The inventor makes three claims for this apparatus.—No. 4430. March 24th, 1887. 8*d*.

MISCELLANEOUS.

COATING SHEETS OF METAL WITH TIN.—*H. Hall, London.*—The object of this invention is to improve the process of coating sheets of metal with tin, terne, or other metal, by preventing all air and moisture from coming in contact with the molten metal. After the plates have been swilled with water they are placed in a bath of hot oil, where the moisture is liberated from them. This bath of oil is placed just above a vessel containing the molten metal, and the oil therein contained is allowed to run over the surface of the metal, in order to protect it from the air. The plates are lifted directly from the bath of oil into the metal, and on their way they are not exposed to the action of the atmosphere. This process minimises the tendency of the plates to oxidise, and the scruff is not so likely to form on the surface of the molten metal. The inventor makes eight claims for the details of the apparatus employed in this process.—No. 704. January 17th, 1887. 8*d.*

CONVEYANCE OF SAND IN PIPES.—*A. C. Henderson, London.* (*P. Bony, Lyons.*)—In most apparatus for conveying sand to a distance by means of pipes, a certain quantity of water is added to the sand, and this mixture is forced by pumps through the pipes. The drawback of this method is that the sand and water wear away the parts of the pumps while passing through them. By the apparatus constructed according to this invention, the pump forces the pure water only, and thus the difficulty of wear is, to a large extent, obviated. The accompanying figure shows the method adopted. Fig. 1 is a transverse section, and Fig. 2 is a longitudinal elevation of the improved apparatus. C is the end of a discharge pipe from a dredging machine having a movable part D F, which can assume the position E F. The sand thus either falls into the receptacle A, or into B, according to the two positions of this movable part. The valves G G¹ are opened alternately to allow the dredgings to fall into A and B. The doors H I in the approach and discharge pipes direct the water under pressure into the vessels A and B according as they are turned on their hinges; and the openings R S T, at the bottom of A and B, are exits for the water. The cylinder K acts as a safety valve when the pressure of the water is too great. Suppose the

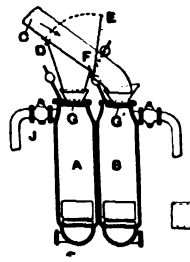

FIG. 1.

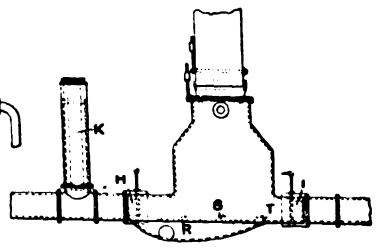

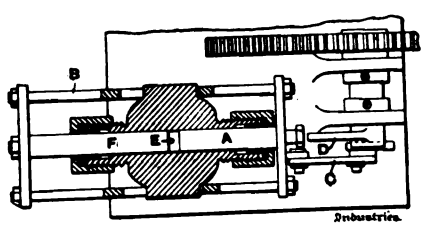

FIG. 2.

sand is directed into the compartment B; when full, the valve D F is changed in position, and the sand is allowed to fall on G¹. The water will be forced by a pump to enter the compartment B through H, and the sand will be discharged through I, while the bulk of the pure water will pass out through the openings R S T. The sand from the dredger will then enter A, and the water therein contained will be caused to overflow through J. The same process takes place with regard to A as happened before in B. These two compartments, and their alternate use, enable the action of the apparatus to be continuous. The same apparatus is applicable to the transport of grain, but in this case the fluid medium is compressed air. The inventor makes one claim. —No. 16596. December 2nd, 1887. 6*d.*

OILING RAGS.—*J. W. Vine, W. Fox, & B. Smith, Leeds.*—The object of this invention is to provide an apparatus for oiling and moistening rags before they are passed into the tearing machine. The apparatus consists of two metal reservoirs placed one within the other, the outer one containing water, and the inner one containing oil. The cover of the oil chamber is finely perforated, so that when the oil is primarily poured into this chamber through the perforated cover it loses most of its solid impurities. The water in the outer chamber is heated by means of a steam coil, in order to liquefy the oil more thoroughly. A series of pipes carry the oil to a long exterior tubular vessel, on the under side of which is a series of fine nozzles for ejecting the oil. A similar tubular vessel also serves as an exit for the hot water. These two series of nozzles side by side distribute the oil and water over the rags in their progress to the tearing machine. The inventors make two claims for this improved oil and water distributor employed for the purpose described.—No. 17653. December 23rd, 1887. 6*d.*

GERMAN PATENT ABSTRACTS.

LUBRICATORS.—*J. Bischoff, Hamburg.*—This lubricator is designed for working against high pressure. F and A are two pistons connected to a frame B, which receives a reciprocating

motion by means of a crank and a connecting rod G. As the frame B is drawn towards the crank shaft, a cam D presses the piston A against F, thereby forcing the oil through E into the cylinder.—No. 41683. April 16th, 1887.

CUT-OFF ARRANGEMENTS.—*C. Hambruch, Berlin.*—This patent relates to an arrangement for cutting off steam, water, or gas mains from a distance by means of a small pressure main. A in Fig. 1 represents a valve casing which is introduced into the respective main, the fluid or gas circulating through P and Q. The cut-off valve B carries on the upper end of its spindle a piston C, while the lower end passes through a stuffing box, and is connected to a weighted lever. The piston C is influenced from the top by the pressure in the pressure main H, and from

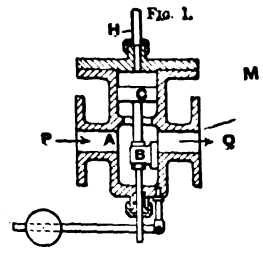

FIG. 1.

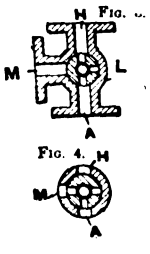

FIG. 3.

FIG. 4.

below by the pressure of the fluid or gas in the main, and these two pressures are balanced by the sliding weight on the lever in such a manner that by cutting off the pressure in H the piston C is forced upwards, thereby shutting Q. The cut-off in H is effected by a three-way cock L shown in Figs. 3 and 4. At M an outlet pipe is arranged through which the water escapes when

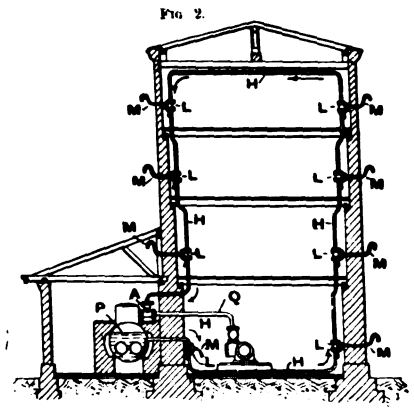

FIG. 2.

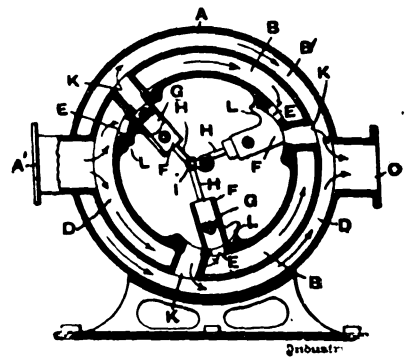
the connection between A and H is interrupted. In connection with this arrangement an automatic brake may be used, and L is in that case a four-way cock establishing a communication between A and the brake as soon as H is cut off. Fig. 2 represents the arrangement of this system in a factory for stopping the engine from any storey of the building. P is the boiler, Q the steam pipe leading to the engine, H a small pressure main supplied by the water in the boiler. L are the three-way cocks, M the outlet pipes, and A the valve casing shown in Fig. 1. The steam passes from the dome of the boiler through A into Q and on to the engine. As soon as one of the three-way cocks is turned into the position shown in Fig. 4, the water in H escapes through M, and the communication between P and Q is interrupted in the manner already described.—No. 41784. June 11th, 1887.

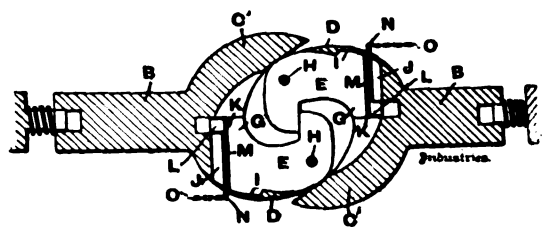
UNITED STATES PATENT ABSTRACTS.



DYEING AND SCOURING MACHINE.—*C. L. Kalander, Philadelphia.*—The dyeing or scouring liquor is contained in a tank, and a shaft is supported in bearings on the opposite walls of the tank at the level of the surface of the liquor. A frame is fitted on the shaft, half of it being immersed in the liquid and half standing above its surface. The frame consists of two circular end pieces, with two concentric sets of rods forming a cylindrical surface between the two end pieces. The skeins of fibre to be treated are stretched between two rods, one in each set, and the whole frame is rotated with the shaft on its bearings. The inner series of rods are adjustable diametrically, so as to adapt the frame to any sized skeins. The outer set of bars are made of a polygonal cross section, and a motion of rotation is imparted to each, so as to gradually turn the yarn. A pin is fixed in the path of these outer bars, in order to give them the intermittent rotation. The inventor makes eight claims for these improvements.—No. 377393, dated 7th February, 1888.

ELECTRIC RAILWAY.—*W. I. Ludlow, Cleveland, Ohio.*—This invention involves an improved construction of the rails used in the electric railroad. A T rail is employed, and is composed of two equal vertical sections, joined at a certain distance apart by means of tie bolts and intervening washers. A space is left above the washers and between the two sections for two non-conducting and insulating strips of india-rubber; and in a cavity between these two rubbers are placed the flat conducting strips of copper. The inventor makes six claims for this arrangement.—No. 377397, dated 7th February, 1888.

EMBROIDERING MACHINE.—*R. T. Smith, Nashua, New Hampshire.* —In this improved machine, threaded vertical shafts and a threaded horizontal shaft engage in threaded recesses in the fabric frame supports, and have gearing mounted on them for their actuation. The movements of the fabric carrying frame are timed and controlled by a perforated sheet or stencil plate having a progressive motion, whereby an electric circuit is made and broken. The reversal of the needle carriages is automatic, and is effected by electromagnetic devices governed by the strain of the threads. The thread tension mechanism is variable, so as to produce designs differing in texture, or so as to produce threads of different sizes. Portions of the fabric may be removed by a punching apparatus automatically and positively actuated and intermittently fed. The distance apart of the cuttings may be varied. The threads are prevented from being withdrawn from the eyes of the needles by a locking device which acts while the threads are in tension. The gripping bars accommodate themselves to needles of any size, and a button hole stitch may be secured at any stage. Duplicate designs can be produced by varying the speed of the mechanism which adjusts the fabrics relatively to the feed of the main controlling element. Tension plates are placed near each surface of the web, whereby the swaying of the web, produced by the strain on the threads, effects through certain levers and electric devices the reversal of each needle carriage. The inventor makes forty-two claims.—No. 377408, dated 7th February, 1888.



REFINING VEGETABLE OILS.—*G. W. Scollay, New York.*—This process consists of refining vegetable oils and of manufacturing paints in one operation. The oil is treated with any one of the ochres that are suitable as paints. The impurities of the oil are combined with the ochre, and the refined oil is easily separated. Thus a double product is obtained. One claim is made.—No. 377406, dated 7th February, 1888.

WATER MOTOR.—*E. F. Ranks, Lewiston, Minnesota.*—This invention involves a new arrangement of pistons, cylinders, and valves. The whole apparatus is contained in the outer casing A, and the water supply enters at A¹ and leaves at C. The annular spaces B B¹ allow the water to pass to and from the cylinders G. The crank shaft goes through the centre of the casing, and the three piston rods H of the three cylinders G are pivoted directly to the crank pin I. The three cylinders G are placed at an angle of 120° with each other, and are pivoted to the outer casing as shown. At the ends of the cylinders where they slide on the surface of the inner casing are guides L, which

serve to steady them in their oscillations, and to close the entrance ports E when the exhaust ports K are opened. Each cylinder in its movements comes in turn opposite the induction and eduction ports E and K which are provided in the inner casing, and thus the cylinders themselves act as their own slide valves. The course of the water is easily understood by reference to the accompanying diagram. The water enters through A¹ and passes into the annular space B. When the cylinders are in turn placed with their ends opposite the ports E, the water enters them and presses the pistons forwards. On exhaust the water passes back through K into the outer space B¹, from whence it escapes through the outlet C. The inventor makes three claims for this water motor.—No. 376610, dated 17th January, 1888.

CAR COUPLING.—*A. J. McGichee, Jackson, Tennessee.*—The accompanying figure illustrates the form of car coupling designed by the present inventor. The two engaging parts placed on each vehicle are similar in shape but reversed in position, so that any two cars may be joined together. The

drawheads B have two tongues C C¹, and a drawbar E is pivoted at H on the tongue C. The rear edge of the drawbar is bevelled, and the notch K is fixed at its hinder end. The notch K engages with a latch L hung on the drawhead. The tongue C is provided with a shoulder D corresponding and engaging with a vertical shoulder I on the drawbar E. Means are also provided for rotating the drawbar E, in order to couple and uncouple the gearing projections on E. The inventor makes two claims for this form of car coupling, for the combination of the tongues C C¹ with the drawbar E, and for the means of gearing the two parts together.—No. 376482, dated 17th January, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE THEORY OF HOT AIR AND GAS ENGINES.

By G. R. Bodmer.

In a series of articles already published under this head (see *Industries*, Vol. I., pages 630, 656, 681), it was stated that the indicator diagram does not give us all the information we require as to the practical efficiency of a heat engine. It is quite possible, as we shall show, that an engine may waste a large amount of heat for which the nature of the cycle, as given by the indicator diagram, would not account. This is the case, for instance, when heat is escaping by radiation and conduction through the walls of a cylinder, while at the same time it is being communicated to the expanding gas; and if both processes take place at the same rate, the result will be as though no heat had been communicated to the gas, the expansion curve being adiabatic. This is what actually occurs with some gas engines. If more heat is supplied during expansion than escapes by radiation and conduction, then only the difference between the quantity communicated and that abstracted will show itself in the diagram.

We have seen that in a perfect cycle, compression is an essential feature. In practice, no perfect cycle, nor even an approximation to one, occurs in hot air or gas engines. There are, however, advantages of a practical nature, apart from thermal economy, to be gained by compression. With a cylinder of given capacity, a greater quantity of work can be developed by compressing the gas before heat is communicated to it, than when this is not the case. This means that into a given space we get a greater weight of gas with compression than without it, and other things being equal, the work done is proportional to the weight of the working substance used. The thermal economy is not necessarily greater with more compression, the advantage being of an essentially practical character, viz., that to do the same work a

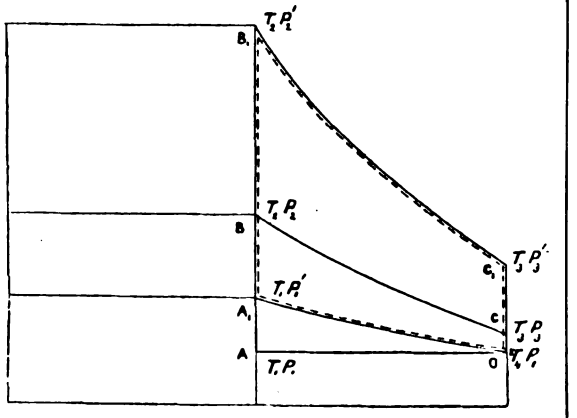

Fig. 1.

smaller cylinder can be used. As an illustration, let us take a practical example. In Fig. 1, ABCD represents an indicator diagram from a hot air engine, working with a permanent gas, having the following cycle: (1) Communication of heat at the constant initial volume V_1 until the pressure and temperature rise from P_1 and T_1 (atmospheric pressure and temperature) to P_2 and T_2 respectively. (2) Expansion adiabatically from the volume V_1 to V_2 the pressure and temperature falling to P_3 and T_3 respectively. (3) Rejection of heat at constant volume V_2 until the pressure and temperature fall from P_3 and T_3 to P_1 and T_1 respectively. (4) Compression from the volume V_2 to the original volume V_1 the pressure remaining constant while the temperature falls from T_1 to T_1. During this operation heat has to be rejected, and although the volume is reduced, as no increase of pressure takes place, compression, in the ordinary practical sense of the term, cannot be said to occur.

The numerical data are assumed to be as follow:—

$$\frac{V_2}{V_1} = 2.$$

$V_2 = 1$ cubic foot.
$V_1 = 0{\cdot}5$ „ „

$P_1 = 14{\cdot}7$ lb. per square inch.
$P_2 = 51{\cdot}45$ „ „ „
$\frac{P_2}{P_1} = 3{\cdot}5$
$T_1 = 460 + 60 = 520$.

If v_1 be the volume of 1lb. of air at atmospheric pressure (air being the permanent gas used), $v_1 = 13{\cdot}088$ cub. ft. at 60° F., then the weight of air used

$$w = \frac{0{\cdot}5}{13{\cdot}088} = 0{\cdot}038\text{lb.}$$

TABLE OF LAWS FOR PERMANENT GASES UNDER THE MOST IMPORTANT CONDITIONS.

J = Joule's equivalent = 772·8 foot-pounds.
T = Absolute temperature = 459·4 + temperature Fahrenheit.

General Formula $H = K_v(T_2 - T_1) + W$.

Nature of process.	Conditions under which it occurs.	Law of expansion.	Work done.	Heat communicated.
Isothermal expansion.	Constant temperature $T_1 = T_2 = T$	$p_1V_1 = p_2V_2$	$W = RT_1 \text{ hyp. log } \left(\frac{V_2}{V_1}\right)$ or $p_1V_1 \text{ hyp. log } \left(\frac{V_2}{V_1}\right)$	$H = W$
Adiabatic expansion.	No heat communicated or abstracted $H = 0$	$p_1V_1^{\gamma} = p_2V_2^{\gamma}$	$W = K_v(T_1 - T_2)$ or $\frac{K_v}{R}(p_1V_1 - p_2V_2)$	$H = 0$
Expansion at constant pressure.	Pressure constant $p_1 = p_2 = p$	$\frac{V_1}{T_1} = \frac{V_2}{T_2}$	$W = p_1(V_2 - V_1)$ or $R(T_2 - T_1)$	$H = K_p(T_2 - T_1)$
Communication of heat at constant volume	Volume constant $V_1 = V_2 = V$	$\frac{p_1}{T_1} = \frac{p_2}{T_2}$	$W = 0$	$H = K_v(T_2 - T_1)$

H = Heat equivalent in foot-pounds communicated or abstracted during process.
T_1 = Absolute temperature at commencement of process.
T_2 = „ „ at end of process.
V_1 = Volume of one pound of gas at commencement of process.
V_2 = „ „ „ „ at end of process.
p_1 = Pressure „ „ „ at commencement of process.
p_2 = „ „ „ „ at end of process.
W = Work done in foot-pounds by one pound of gas during process.
K_p = Specific heat equivalent in foot-pounds at constant pressure = 183·5 } for dry air.
K_v = „ „ „ „ „ volume = 130·2 }
γ = Ratio of specific heat at constant pressure to specific heat at constant volume = 1·408.

By the formula given in the table, we can calculate the value of P_3 the pressure at the end of the expansion

$$\frac{P_1}{P_2} = \left(\frac{V_1}{V_2}\right)^{\gamma}$$

the ratio of the actual volumes is, of course, the same as that of the specific volumes where the same weight of gas is dealt with, hence

$$P_3 = \left(\frac{V_1}{V_2}\right)^{\gamma} P_2$$

$$P_3 = (0{\cdot}5)^{1{\cdot}408} P_2 = \frac{51{\cdot}45}{2{\cdot}653} = 19{\cdot}39\text{lb. per square inch.}$$

$\frac{T_2}{T_1} = \frac{P_2}{P_1}$ the volume being constant, hence

$$T_2 = 520 \times 3{\cdot}5 = 1820°$$

$\frac{T_3}{T_2} = \frac{P_3 \cdot V_2}{P_2 \cdot V_1}$ by the law of Boyle and Charles.

$$T_3 = 1820 \times \frac{19{\cdot}39 \times 2}{51{\cdot}45 \times 1} = 1371°$$

$\frac{T_1}{T_1} = \frac{V_2}{V_1}$ the pressure being constant, hence

$$T_1 = T_1 \frac{V_2}{V_1} = 520 \times 2 = 1040°.$$

The work done during expansion will be:

$$W_1 = wK_v(T_2 - T_3) = 0{\cdot}038 \times 130{\cdot}2(1820 - 1371)$$
$$W_1 = 2221{\cdot}472 \text{ foot-pounds}$$

the work expended on reduction of volume at constant pressure:

$W_2 = P_1(V_2 - V_1) = 14{\cdot}7 \times 144 \times 0{\cdot}5 = 1058{\cdot}400$ foot-pounds

The effective work done is:

$$W = W_1 - W_2 = 1163{\cdot}072 \text{ foot-pounds.}$$

Now, suppose that, instead of reducing the volume at a constant pressure P_1 from V_2 to V_1, we allow the pressure to increase, keeping the temperature constant at T_1; under these conditions, starting from the volume V_2, and compressing to that V_1, the pressure will increase from P_1 to P^1, P^1 being to P_1 in the ratio of V_2 to V_1, or 2 to 1. (*Vide* Fig. 1, ABCD.) If, then, we again communicate heat at constant volume, until the same temperature as before is attained, it is evident that the corresponding pressure will be twice as great, $P^1{}_2 = 102{\cdot}90$. Adiabatic expansion then takes place to the original volume V_1, the expansion ratio being as before. The ratio of initial to final pressure will also have the same value, and, therefore, the final pressure $P^1{}_3$ be double that previously obtained; the absolute temperature T_3 remains unchanged, $T_3 = 1371°$.

The pressure then falls again to P_1, and temperature to T_1, while heat is rejected. The work developed during expansion in this case is:

$$W^1{}_1 = w^1K_v(1820 - 1371).$$

It is evident that the work performed per pound of air has the same value as previously; but the weight of air working in the cylinder has been doubled.

In the first case, we had the volume V_1 at atmospheric pressure and temperature to start with; in the second case, the volume $V_2 = 2V_1$ under the same conditions of pressure and temperature. The work done during expansion, therefore, is, in the second case, twice as great as in the first, with double the weight of the working substance. It is also evident that the quantity of heat communicated at the constant volume V_1 is twice that required previously, the range of temperature being the same, but the amount of air to be heated double.

The work expended in compression at constant temperature T_1 is expressed by the formula—

$$W^1{}_2 = P^1V_1 \text{ hyp log } \left(\frac{V_2}{V_1}\right) \quad P^1 = 2P_1 = 29{\cdot}4 \times 144$$

The hyperbolic log of $\left(\frac{V_2}{V_1} = 2\right)$ is 0·6931

$$W^1{}_2 = 4233{\cdot}6 \times 0{\cdot}5 \times 0{\cdot}6931 = 1467{\cdot}154 \text{ foot-pounds.}$$

As we have shown,

$$W^1{}_1 = 2W_1 = 4442{\cdot}944$$

Hence $W^1 = W^1{}_1 - W^1{}_2 = 2975{\cdot}790$ foot-pounds

It will be noted that the net work done in this case is more than twice as great as in the former, with twice the quantity of heat, which means that a smaller proportion of heat has been rejected, so that in this instance we not only get more work with a given cylinder by compression, but also improve the efficiency of the cycle. The latter effect is due to the nature of the cycle having been altered. If, working between the same temperatures, greater compression be used with the same kind of cycle, then there will be no improvement in the thermal efficiency; but more work will be obtained from a given cylinder.

Generally speaking, the process taking place in a hot air engine is as follows: (1) compression of air, admitted to the cylinder at atmospheric pressure, to some higher pressure, with or without rejection of heat; (2) communication of heat either at approximately constant volume, or during expansion, or both; (3) expansion without further communication of heat; and (4) rejection of heat at constant volume, or during expansion, until the original pressure is reached.

In most so-called hot air engines, the heat to be converted into energy is generated in a furnace of some kind outside the working cylinder, and communicated through the walls of the latter; or the hot products of combustion are admitted into the cylinder, and there allowed to mingle with the working air or gases.

In gas engines, the heat to be converted into energy is produced by the combustion of gas, and in most cases this combustion is so rapid as to constitute an explosion; but this is by no means essential.

The combustion in gas engines, as a rule, takes place within the cylinder itself, and in consequence of this,

Note.—The pressures are given in pounds per square inch, but where they are used otherwise than in ratios, must be multiplied by 144, to express them in pounds per square foot, the unit of measure being the foot.

Digitized by Google

a portion of the working gases undergoes a chemical change, which has to be taken into account in calculations regarding the operations of the engine. Generally speaking, however, gas engines can be treated essentially in the same manner as hot air engines.

So far, the cycles referred to have all been closed cycles; in practice, the great majority of heat engines have open cycles. In a closed cycle, the same working substance is used over and over again, and never leaves the cylinder. In an open cycle, at every repetition of the latter, for every working stroke, a fresh charge of the working substance is admitted to the cylinder, and expelled when the cycle is completed. For the purpose of thermo-dynamic

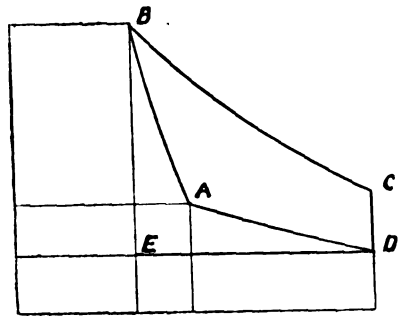

Fig. 2.

investigation, however, the diagrams obtained from open cycles may generally be treated as though they represented closed ones. Take, for instance, the diagram ABCDE, in Fig. 2, to represent an open cycle; the horizontal straight line DE records that part of the cycle during which air or gas is drawn in, and finally expelled at atmospheric pressure. No work (approximately) is required for this—that necessary for overcoming friction does not appear in this place—the pressure of the atmosphere on one side of the piston being balanced by that on the other, so that no further notice need be taken of this part of the diagram. After the air or gas is drawn in, it is compressed according to the curves DA and AB, and expanded according to BC; during all this period communication with the air outside the cylinder is cut off, so that this part of the cycle is a closed one. During the periods AB and BC heat is communicated, that is, during the closed portion of the cycle. When C is reached, communication with the atmosphere is established, and the air or gas in the cylinder blown off until the pressure is reduced to that of the atmosphere, and then the residue is expelled at that pressure, this latter operation being represented by DE.

The work done is measured by the area ABCD, irrespective of whether the cycle be closed or open. We have seen that Work done = (Heat communicated) − (Heat rejected) for a closed cycle; if the two first quantities are the same for an open as for a closed cycle, it follows that the third, the heat rejected, must also be the same. Although, therefore, the rejection of heat in the open cycle takes place practically in quite a different way to that occurring with a closed cycle represented by the same diagram, the net result is identical.

The foregoing table gives a tabular statement of the conditions and formulæ for the most important changes occurring in the state of a permanent gas, which will be useful for reference. All the quantities refer to one pound of gas, and the volumes given are the specific volumes occupied by one pound of gas at the corresponding pressure and temperature. Where the ratios only of the volumes occur, it is immaterial whether the specific or actual volumes are taken; it is often more convenient to make use of the latter.

NOTES ON SCREWING APPLIANCES.

III.

(Continued from page 106.)

In our last article the design and proportions of taps were commented upon, and in the present article an attempt will be made to fully discuss the design and manufacture of screw stocks, screwing machines, and chasers. Before commencing, however, we should remark that two of the illustrations in our last article were incorrectly numbered—Fig. 5 should have read Fig. 7, and inversely. There are three different types of screw stocks now in use, and they may be classed as "guide screw stocks" with three dies, "guide screw stocks" with two dies, and solid screw plates. Two methods of adjustment of the dies are adopted by makers, some preferring to adjust the dies by one of the handles, which serves the purpose of a screw; and others make both the handles and the body of the stock in one piece, and adjust the dies by a screw specially fitted for that purpose. The Whitworth "guide screw stock," the most useful and durable screw stock ever introduced, was designed by Sir J. Whitworth & Co., many years ago, and it is still the best kind of screw stock obtainable (see Fig. 1). The thread cut by this stock is only slightly inferior to that obtained in a slide lathe with a guide screw. The large die is fixed, and is not intended to do much of the cutting, but rather to act as a guide, whilst the thread is cut by one or other of the small dies, according to the direction in which the stock is being rotated; for only one of the

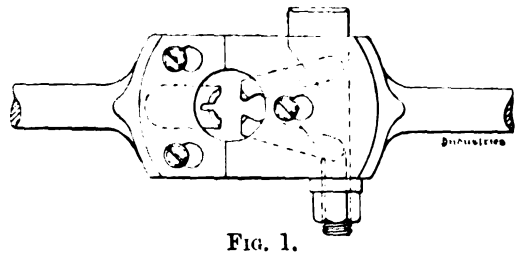

Fig. 1.

small dies can cut during rotation, as will be understood from the illustration. The small dies slide in grooves cut in such a manner that the cutting edge of each small die is always moved forward towards the centre in a radial direction, thereby acting in a manner similar to a chaser fixed on the slide rest of a lathe, so that the cutting edge is just level with the centres. Both inclines of the wedge must be so arranged that each die is moved forward by exactly the same amount, otherwise only one of the dies would cut properly, the other one having little or nothing to do. The stocks are drop-forged, and the handles drawn out under a Ryder forge or small steam hammer—whichever may be found convenient. The handles are then turned, the body shaped to gauge for thickness and breadth, and the slot for the wedge drilled to a case hardened gauge, and drifted out. Then the centre hole and the slots for the dies are drilled out to a case hardened iron template with ordinary drills and slot drilling machines respectively. In the same way, the cover plate and stock are drilled for the cover plate screws, and after the holes are tapped the stock is polished and case hardened. The dies are then fitted by hand, the thread cut by a "full master tap," for reasons given in the last article, and the dies are then finished off by hand, and hardened. This hardening requires no special care, as the pieces are so small that they are only liable to one change in hardening, viz., expansion. After hardening, the dies are ground on a copper wheel to fit their own stock, as the case hardening of the stock prevents the dies being made interchangeable, for the reason that very few stocks expand the same amount, even if made of the same material and hardened at the same time. The alteration in hardening is not

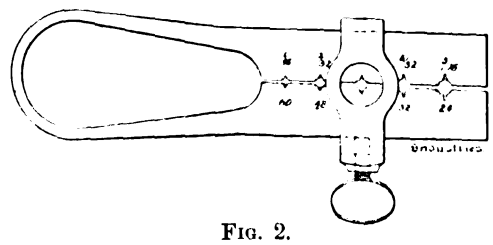

Fig. 2.

even uniform in the same stock, one of the small grooves being nearly always larger than the other after hardening, although shaped out by the same drill. Usually only eight sizes of stocks are made, to screw all sizes from $\frac{1}{8}$in. to 3in. diam.; (1) from $\frac{1}{8}$in. to $\frac{3}{16}$in.; (2) from $\frac{1}{4}$in. to $\frac{7}{16}$in.; (3) from $\frac{1}{4}$in. to $\frac{5}{8}$in.; (4) from $\frac{1}{2}$in. to 1in.; (5) from $\frac{3}{4}$in. to 1$\frac{1}{4}$in.; (6) from 1in. to 1$\frac{1}{2}$in.; (7) from 1$\frac{1}{4}$in. to 2in.; (8) from 2$\frac{1}{4}$in. to 3in. The smallest size is, however, very rarely used, as the thread on the screws it will cut is so small that it is preferable to have fewer loose pieces, and consequently the two-die stock is more frequently used for cutting screws of small sizes; but it is doubtful whether in this case even the two-die stock is equal to the small spring stock shown in Fig. 2.

Spring Stocks.—The action of the spring stock shown is precisely the same as the two-die stock; but it is much more convenient to handle. The threads are cut by a "full master tap," as already described.

Two-die Stocks.—This type of screw stock is the cheapest of all adjustable die stocks, on account of its simple construction; but it is inferior to the three-die stock in every way. A small notch is cut at the centre of each die, and the edges of these notches have to serve as cutting edges, and do all the cutting if the dies have been cut by a "full master tap." The slot is made so narrow to prevent weakening the die that there is not enough room for the cuttings, and the efficiency of the cutting edges is thereby reduced. Again, the notches are so shaped (see Fig. 4) that the cutting edge cannot be sharpened on a grindstone, like the dies of the three-die stock, but must be softened and filed up, and this method involves loss of time, and injures the thread. The cutting edges cannot be made so keen as those of the three-die stock, and, consequently, a longer time is taken to do equal amounts of work. The thread is sometimes cut by a "plug master" tap, and it is obvious that, in that case, as soon as the bolt is screwed down to the size of the "plug master tap," the whole thread surface of the dies hugs the thread of the bolt, and the cutting edges no longer act (see Fig. 3). This is rather an advantage while the dies are new, as it prevents the bolt being screwed too small; but after the dies have begun to wear it is impossible to cut a bolt as small as the plug master tap, and a good deal of trouble is experienced from tight bolts. This difficulty is avoided by some manufacturers by making the plug master taps $\frac{2}{1000}$in. or $\frac{3}{1000}$in. below the standard gauge. In this way the trouble from tight bolts is avoided; but it is an objectionable practice, as

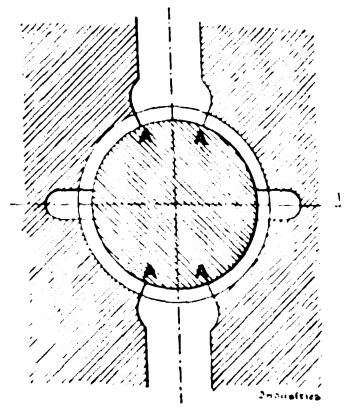

Fig. 3.

the thread traced on the bolt at the commencement of the operation is of a different pitch to that of the finished thread, and the thread is therefore defective at intervals along the bolt. The dies should have been cut with a full master tap; the thread first traced on the bolt would then be of the proper pitch, and the cutting edges would cut as well at the end as at the beginning of the operation (see Fig. 4). In this way it is possible to cut a bolt smaller than the gauge if necessary. The only objection to using a full sized master tap for cutting these dies is that when the thread is nearly finished, some care is required to keep the stock steady on the bolt, and prevent it from getting slightly jammed, for if this occurs —and it is not always easy to prevent it—the dies will cut deeper in that place, and the thread become uneven. The dies in Fig. 3, which were cut by a plug master tap, present a much better bearing surface on the bolt as the thread approaches completion, and on this account are not liable to get jammed, while the thread cut is generally smoother than if a "full master" had been used for cutting the dies. Therefore we have in making two-die

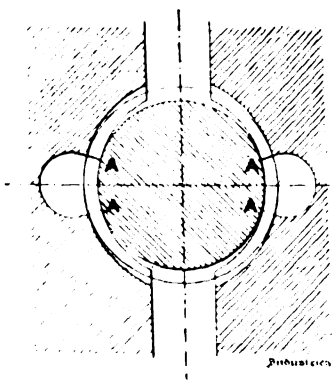

Fig. 4.

stocks to choose between the evils of each pattern, and, all things considered, the dies in Fig. 4 are to be preferred. The screw stock is an imperfect machine at the best, but is nevertheless a very useful one, and its defects appear to be more important than they really are.

The Solid Die Screw Stock.—This is obviously the cheapest stock made, and though it will do for rough work it is not so good a tool as those already described. If there be only one die for each size, the cut it takes in forming a thread is so deep that a smooth surface can hardly be looked for, unless a strong jet of soapy water is directed on the dies whilst cutting; but this defect is obviated by having two or three holes for each size. At the Patent Nut and Bolt Company's Works, Birmingham, solid dies, which cut a full thread at one operation, are largely used, and with very good results. Each die will cut about one hundred gross of bolts before requiring any repairs. The cutting edges cannot be sharpened when dull except by softening and filing the die, but the thread is thus injured by scaling. As there is no means of adjustment, the only way of rectifying the wear of the die is to close it in with the hammer when red hot, and tap the hole again with the

Digitized by Google

plug master tap. The dies should never be thinner than the diameter of the bolt to be screwed, and the hole in the die must be tapped a little larger than the standard gauge, to allow for the contraction of the hole in hardening. The grooves should always be made as large as convenient. Three is the most usual number, and it should always be remembered that an odd number of cutting edges causes the die to cut steadier, and turn out better work than if it had an even number of grooves.

Screwing Machines.—These may be divided into three classes, viz.: Machines with revolving die boxes; machines with the die boxes fixed, in which case either the rod or the die box may be arranged to travel during the operation; and machines with solid dies, which may either have fixed or revolving dies, and either the die or rod may travel as the rod is screwed; but the motion of the machine has to be reversed to get the die off the rod when screwed. The first two machines have few faults, and equally good results as regards efficiency and convenience may be obtained with either. The solid die machine is less efficient than either of the others, for the reasons already given, and also because much time is expended and injury done to the dies by reversing the machine and running the dies the opposite way on the rod or bolt. With a well made case hardened die box for expanding dies no trouble is ever experienced from slackness of the die, which is the only argument urged against expanding dies.

Die Boxes.—Formerly four dies were used in the machines for screwing bolts at one operation, and these were moved in and out by right and left hand screws; but it is now the almost universal practice to have only three dies, and to move these forward by means of a cam. This is, however, by no means a new arrangement, as a screwing apparatus of this design is still in existence capable of screwing up to 2½in. diam. bolts, which was made by Whitworth so far back as 1835, and it differs in no way from the designs of other makers, who have since obtained patents for the very same arrangement. Why Sir J. Whitworth's design was abandoned to make way for the four-die apparatus it is difficult to say, but it is a fact

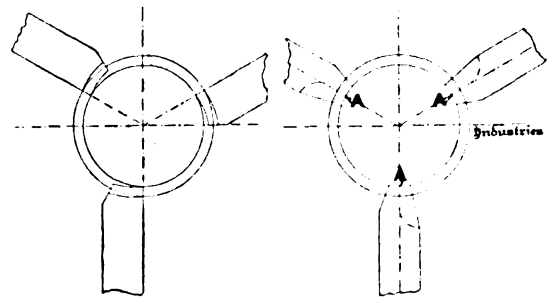

Fig. 5. Fig. 6.

that the idea was first put into practice at Whitworth's works over fifty years ago. Fig. 5 shows the best arrangement for a three-die screwing apparatus; the face of each die is a radial line, or even more acute, like a turning tool, to render the work easier, and the groove in which the die moves is arranged in such a manner that the cutting edge always moves along the same radial line, and thus is always in the proper position with regard to the rod, no matter what distance it is from the centre. This may appear a very trivial matter; and as all screwing machines are now made to "screw a full thread at one operation," it may seem unnecessary that the cutting edge of the die should move always along the same imaginary radial line. But such is not the case; for if the die box be constructed as shown in Fig. 6 (and one eminent firm has done this for years), with the cutting edge in advance of the radial, parallel to the motion of the die, it follows that no bolt can be screwed below the standard size, or even so small as the standard size, after the dies are a little worn. The reason is that if the dies were moved forward to screw a slightly smaller size, the bolt would rub on the centre of the thread at the point A, and the cutting edge would not be in contact with the work at all. It is thus impossible to screw a bolt below the gauge with this arrangement, in case the dies have been cut by a plug master tap; and if a full sized master tap were used for cutting the dies, the apparatus would scarcely work at all. In the construction, as shown in Fig. 5, either of these taps may be used for that purpose, although the plug master is the proper one to use. This defect has been remedied by using a tap smaller than the gauge for cutting the dies in Fig. 6; but by far the best plan would have been to grind away the die to the dotted line shown in Fig. 6, and when making new die boxes to move the slot a little further back, as this is the only difference in the two arrangements.

Depth of Dies.—The depth of dies, that is, the number of threads, is an arbitrary feature. In screw stocks the depth of die is generally a little less than the diameter of the bolt, and the thread is not tapered at either top or bottom of the die; but dies for screwing apparatus which have to cut a full thread at one operation, vary from 2½ diam. to less than 1 diam. in depth. For instance, the dies for cutting ¼in. screws are ⅝in. deep; for 1½in. screws, 1⅜in. deep; while for 3in. screws they are only 2¼in. deep, and the first five or six threads are tapered, the first thread being almost completely removed.

NOTES ON FOUNDRY WORK.

By the Author of "Pattern Making."

(Continued from page 133.)

XIII.

The Shrinkage of Castings.—For several years it has been my practice to note down for my own private instruction and guidance, sundry notes relative to the shrinkage and buckling of castings. Having had abundant facilities for doing this, as part of my ordinary duties, I have collected a large amount of data relating to iron castings moulded in dry and green sand, to cast steel, and to tough gun metal, as ordinarily used by engineers. From these I will select a number of typical examples.

It is, sometimes, not an easy task to satisfactorily decide the allowance for contraction, or the provisions against possible curvature in cooling, and the only way of doing either with a degree of accuracy is to profit by past experience. In proportioning similar, but not identical, parts, great judgment ought to be exercised, since it is surprising how a slight alteration in the disposition of metal, and the conditions of cooling, will sometimes affect the ultimate result. General rules may be safely deduced; but beyond these, the proportioning of each piece of work must be decided by its individual characteristics, and as a matter of judgment. Since appearances and deductions therefrom are often deceptive, owing to the swelling of the mould, and to rough and clumsy ramming, rapping, and mending up, I have observed special care in selecting these examples, giving only those furnished by the best, truest, and cleanest castings, made under the most favourable conditions of moulding, and preferring also horizontal to vertical measurements, since metal is more liable to "gather" or increase in thickness than in width, on account of the pressure of the molten metal, and the springing and lifting of the boxes. Since rules slightly differ occasionally, I have always used the same rule for measuring both patterns and castings. Figs. 86 to 97 represent useful types of castings in ordinary iron. The pattern maker's contraction rule gives an allowance for shrinkage of ⅛in. in 15in.; but this is only approximately correct, as will be shown further on. In the centre piece for a turntable of 50ft. diam. (Fig. 86), the shrinkage at A, 3ft. 9in. diam., was barely ⅛in., and that at B, 3ft. 11in. deep, the same. This is a very small amount; but it was a stiff, heavy casting, made in dry sand, and had to shrink around a hard, unyielding central core. Castings in dry sand and in loam usually contract rather less than those made in green sand. The latter yields more to the shrinking metal, and slightly chills the exterior of the casting, causing it to shrink suddenly, compressing the interior mass. Hot iron possesses the power of accommodating itself to some extent to the resistance of hard baked cores. Founders know this, but they also know that there is a limit to this power of accommodation; and that weak castings will fracture rather than yield—the poorer the quality of the metal is, the more readily they crack. Once I saw a 4ft. branch pipe, ¾in. thick, cast on end, fractured for a distance of 1ft. or more downwards from the top, because the dry, bricked up core was not removed on the night of casting, but left until the next morning. Hence in weak cylindrical castings, whether large or small, and in all cylinders of large diameter cast in dry sand or loam, it is quite necessary to dig out some portion at least of the core, while the metal is at a red heat. In loam moulds, loam bricks are commonly inserted for this purpose, four vertical layers of brick being inserted equi-distantly between the common bricks, and these loam bricks are broken up with the crowbar soon after the metal has set. In cases where the metal is of sufficient thickness and strength, the loam bricks will yield to the shrinkage. In casting light pipes, the core bars are drawn out as soon as the metal has solidified. In the particular casting shown in Fig. 86, the mould was made of dry sand, and the shrinkage was in a large degree stayed by the hard central core, which remained undisturbed until the casting was quite cool. As the core portion was large in relation to the bulk of the casting, and the latter was strong, the shrinkage was diminished without risk of fracture, especially as the metal used in casting consisted of a mixture of strong iron, which contracts less than the softer and more open metal. Lastly, metal which is cooled slowly shrinks somewhat less, forming larger crystals than that which is cooled rapidly, and in a dried mould the cooling and shrinkage are more equable than in a green sand mould permeated with moisture. To these causes collectively I attribute the exceptionally slight amount of shrinkage of the casting shown in Fig. 86.

The fact of the contraction in the vertical direction being slight or altogether absent in castings of which Fig. 86 may be taken as a type, and also in all shallow or plated work, if judged by comparative measurements of pattern and of casting, has induced a general belief that there is little or no vertical shrinkage. When unimpeded by the presence of cores, and when the mould is not "strained," that is, when the liquid pressure does not lift the cope, or press down the yielding sand, the shrinkage of metal is doubtless the same in the vertical as in the horizontal direction. Fig. 86 is an example of a rather shallow casting, which showed little shrinkage in the vertical direction. I may here also give as an example the case of a solid block of iron, used as a balance weight, and measuring 2ft. 11in. by 13in. by 22in. deep, in which the pattern and casting measured precisely alike. As there were no cores, and as the blocks—there were four of them—were cast in green sand, the absence of shrinkage must be due to the mould straining. But as a proof that castings do shrink the average amount in the vertical direction, I give my measurements of a hydraulic cylinder. It was 11ft. 2¾in. long by 18in. outside diameter; the thickness of metal was 2in., and it was cast on end. The total vertical shrinkage was 1 $\frac{3}{16}$in., or about ⅛in. in 14in., or scarcely different from the normal amount. But here everything favoured contraction, and the area at top and bottom was so small relatively to the length that little straining action could occur. Taking the casting (Fig. 87) as an illustration of conditions very different from those in Fig. 86, we have a confirmation of the inferences just deduced. This ring was cast in green sand, and cooled in the sand, without any part of the mould being removed. The green sand being loose and open, in comparison with the core in Fig 86, offered no resistance to the contraction of the massive ring, and the shrinkage at A was $\frac{7}{16}$in. in 3ft., or ⅛in. in 10in. The metal was not so tough as that in the previous case. Fig. 88 is an example of a similar type of casting. It is an internal toothed wheel, and moderately heavy, and there is only the body of green sand in the central space. Consequently, the contraction in this case was also large, being ⅝in. in 4ft. 5in. at A, or ⅛in. in 10⅝in. The ring of the section shown in Fig. 89 has a diameter of 12ft. 4in. at A, and shrunk 1¼in., or ⅛in. in 14¾in. The section of this ring is very light proportionately to the diameter.

The casting shown in Fig. 90 differs but slightly in proportion from Fig. 88, but the contraction at A was fully $\frac{5}{16}$in. in 3ft. 7½in., being about ⅛in. in 17in., or very much less than that in Fig. 88. Fig. 90 represents a cog wheel of 1⅝in. pitch, which was cast in green sand of good iron. The only marked difference between Fig. 90 and Fig. 88 is that the former has a central boss connected to the rim by six arms of T section. A wheel of identical section, but of slightly different dimensions, having 1⅞in. pitch instead of 1⅝in., as in the last example, shrunk a little less. The diameter at A was 4ft. 6 $\frac{7}{16}$in., and the total contraction amounted to $\frac{7}{16}$in., being about ⅛in. in 16in. These examples show that the presence of arms or ribs retards contraction. It is not very easily explained why this should be the case; but it is nevertheless certain that the presence of straight arms in any casting, whether wheel, bed plate, or frame, diminishes contraction. I venture to suggest the following explanation: There is more metal in a wheel with arms than in a ring, the bulk of the metal being in the boss. The comparatively light ring has a large area exposed to the chilling influence of the sand, and radiates heat outwards, thereby cooling rapidly. But while cooling it is prevented from shrinking to its full amount by the arms and boss, which have a higher temperature, and have consequently not shrunk so much as the rim. There is a certain tension in the arms and boss after they have ultimately shrunk to their full extent, because the rim has by that time set too firmly to yield to the inward pull. In this way contraction is retarded throughout. The shrinkage of engine cylinders depends upon their size. That shown in Fig. 91 was cast in dry sand, and shrank more than was anticipated. Length A shrunk $\frac{1}{16}$in. in 3ft.; B ⅛in. in 2ft. 3⅛in.; and C barely ⅛in. in 1ft. 11in., these figures giving a shrinkage of about ⅛in. in 12in. In small cylinders ranging from 7in. to 10in. in diam., the shrinkage is almost inappreciable, so that it is quite safe to allow for only one half of the contraction given by the ordinary rule. This slight shrinkage may be attributable to the fact that they are cast in dry sand, of strong metal, and that they enclose numerous cores. But the larger the cylinder, the larger becomes the shrinkage proportionally, since the metal is relatively less, and the enclosed cores offer less relative resistance to shrinkage. The contraction of pipes and columns lengthwise is quite that given by the pattern maker's rule, there being nothing to set up resistance. In the two examples illustrated in Figs. 92 and 93, the shrinkage was in the first case 1⅝in. in 12ft. 6in., or ⅛in. in about 13⅝in.; in the second, 1 $\frac{1}{16}$in.

Industries.

in 11ft., or $\frac{1}{8}$in. in about 15$\frac{1}{2}$in. As bearing out the deduction that mass slightly reduces shrinkage, I noted that a column with $\frac{3}{4}$in. metal shrunk rather less than one with $\frac{1}{2}$in. metal. Taking similar examples: An 8in. pipe, 9ft. $\frac{1}{4}$in. long, with $\frac{1}{2}$in. metal, shrunk 1$\frac{1}{8}$in., or exactly $\frac{1}{8}$in. per foot. A fluted column, 11ft. 3$\frac{1}{2}$in. long, 8in. outside diameter, having $\frac{3}{4}$in. of metal under hollow of flutes, shrunk 1$\frac{5}{16}$in., or about $\frac{1}{4}$in. in 13in. A short pipe, 4ft. 8in. long, 4$\frac{3}{4}$in. core, $\frac{5}{8}$in. metal, shrunk $\frac{1}{8}$in., or $\frac{1}{8}$in. in 1ft. 2in. I have measured many pipes and columns, both large and small, and these are average examples of results which show general uniformity. The contraction of plain plates is about that given by the rule. Fig. 94 is a chequered foot plate $\frac{1}{2}$in. thick, and the contraction both in length and width was $\frac{1}{8}$in. in 15in. A packing block measuring 1ft. 11$\frac{5}{8}$in. by 14$\frac{1}{2}$in. by 1$\frac{3}{4}$in. thick, shrunk at the rate of $\frac{1}{4}$in. in 20in. Again a plain oblong plate, 4ft. by 2ft. by $\frac{5}{8}$in., almost identical in size with Fig. 94, shrunk $\frac{7}{16}$in. in length, and barely $\frac{1}{4}$in. in width, or about $\frac{1}{4}$in. in 1ft. 2in. A common tank plate, 4ft. square, $\frac{7}{16}$in. thick, shrunk $\frac{7}{16}$in. each way, or about $\frac{1}{8}$in. in 1ft. 2in. A plate 3ft. 6in. by 3ft. 8in. by 1in., shrunk $\frac{1}{8}$in. in 15in. A boiler maker's levelling block (Fig. 95), intended for putting together some turntable framings made of channel iron, contracted $\frac{1}{8}$in. in 18in. The casting in this case was 3in. thick. The block illustrated in page 368, Vol. III. (Fig. 41), which was 6ft. 1in. long by 4ft. 6in. wide by 3$\frac{1}{2}$in. thick in the plate itself, and having ribs 5in. deep, shrunk $\frac{1}{8}$in. in length and $\frac{3}{8}$in. in width, or about $\frac{1}{8}$in. in 18in. Though below the normal rate, this was rather more than I expected in this massive casting; but the numerous small round cores probably facilitated shrinkage. A marking off table (Fig. 96), 2in. thick in the plate, and having ribs 4$\frac{1}{4}$in. deep, shrunk $\frac{1}{16}$in. in a length of 10ft., and $\frac{5}{16}$in. in a width of 3ft. 6in., or about $\frac{1}{8}$in. in 16in. An angle piece of the section shown in Fig. 97, 8ft. 3$\frac{1}{2}$in. long, shrunk $\frac{3}{4}$in., or $\frac{1}{8}$in. in 16$\frac{1}{2}$in. Many similar instances might be given, but enough has been stated to indicate where maximum and minimum shrinkage is to be anticipated, and allowance should be made accordingly.

Chilled castings, and castings made of hard white iron, shrink very much, subject, however, to modifying influences. Fig. 98 is a coned roller, chilled on the conical surface. This shrank $\frac{7}{32}$in. in 11$\frac{3}{4}$in., or $\frac{1}{8}$in. in about 7in. Fig. 99 shows a thin plate 2ft. in diameter, chilled on face and edge, which contracted only $\frac{1}{4}$in., or $\frac{1}{8}$in. in 12in. But in Fig. 98 the chilled surface was large relatively to the size of the roller, and was so situated that the contractile influence of the cold chill acted at once throughout the thin wall of metal. Hard white iron is highly contractile. This must not be confounded with strong iron like that used in Fig. 86, and for engine cylinders, which shrinks least of all. The fire bar (Fig. 100) shrunk $\frac{1}{2}$in. in length, being $\frac{1}{8}$in. in 9in., or nearly twice the normal amount.

The contraction of steel is very different from that of iron, and I have made numerous notes of its behaviour, from which I select a few illustrations. My knowledge has been obtained by comparing the dimensions of castings with those of patterns which I have sent to various steel works, and I conclude that steel contraction is generally about three times that of iron. For crucible cast steel, from $\frac{3}{16}$in. to $\frac{5}{16}$in. per foot may be taken as a fair average allowance, varying with the nature of the casting. In a spur pinion (Fig. 101) of 12in. diam., the shrinkage at A was $\frac{3}{8}$in. In a pinion of a similar kind 2$\frac{1}{4}$in. pitch, measuring 10$\frac{3}{4}$in. at extreme diameter A, the shrinkage was $\frac{9}{32}$in. In another of 3$\frac{1}{2}$in. pitch, measuring 13$\frac{7}{8}$in. over all, the difference in pattern and casting was barely $\frac{3}{8}$in. In a bevel pinion (Fig. 102) the result was about the same, the shrinkage at A being $\frac{1}{4}$in. in 10in., and I found that the difference in diameter of this same pinion when cast in iron and in steel was $\frac{1}{4}$in., the iron showing really no contraction, which again corroborates my previous remarks as to mass diminishing shrinkage. Similar examples go to prove that while heavy iron castings contract less than light ones, heavy steel castings shrink to the maximum amount. In trolly wheels the metal is less in mass than in the pinions in Figs. 101 and 102, and they shrink proportionately less. Thus, taking several wheels of the outline shown in Fig. 103, the shrinkages were as follow: One 18in. in diameter at A contracted barely $\frac{3}{8}$in.; one, 21in., just $\frac{3}{8}$in.; another, 18$\frac{3}{4}$in., $\frac{3}{8}$in.; one, 2ft. 6$\frac{9}{16}$in., $\frac{5}{8}$in. Across the flanges B the shrinkages were in 19$\frac{3}{8}$in., $\frac{3}{8}$in.; in 22$\frac{1}{16}$in., $\frac{7}{16}$in.; in 20$\frac{7}{8}$in., $\frac{1}{2}$in.; and in 2ft. 8$\frac{1}{2}$in., $\frac{11}{16}$in. Two plated cog wheels of 2$\frac{1}{8}$in. pitch gave respectively $\frac{1}{2}$in. of shrinkage with 20$\frac{5}{8}$in. diam., and $\frac{7}{16}$in. with 19in. A turntable cap (Fig. 104) shrunk $\frac{9}{16}$in. in a diameter of 2ft. 2$\frac{1}{4}$in. A short casting of girder section, averaging about $\frac{1}{2}$in. thick, shrunk only $\frac{5}{32}$in. per foot—or about half that of Fig. 101.

The contraction of gun metal I have found to be so nearly uniform in castings of various shapes, that I may state that $\frac{1}{8}$in. in 10$\frac{1}{2}$in. will be an accurate average allowance in almost every instance. Sometimes, as in heavy castings, the shrinkage will be found rather less; but it is seldom, if ever, more. I will give a few examples without illustrations. A ring 16in. in diameter, having a cross section of 3in. deep by 1$\frac{1}{16}$in. thick, shrunk $\frac{3}{16}$in.; a hollow plunger, 13in. long by 3in. diam., shrunk fully $\frac{1}{8}$in. in length; a plated sheave pulley, 10$\frac{1}{2}$in. diam. over rim by 2in. wide, shrunk $\frac{1}{8}$in. in diameter; but a heavy worm wheel blank, 15$\frac{5}{8}$in. diam. on the central plane, shrunk only $\frac{1}{4}$in. in all; various facing pieces of different lengths, some straight and some curved, used for penstock doors, all shrunk uniformly $\frac{1}{8}$in in 10in.

Some experience of the changes of shape which castings undergo by reason of shrinkage strains is necessary, in order to proportion them correctly. I have seen numerous massive and very strong looking castings fracture during cooling, or a long time afterwards while lying in the yard untouched, or while being machined; the reason being that excessive contraction in one portion had put adjacent parts into a condition of great tension. By putting an excess of metal into some vulnerable point of a casting, is introduced an element of weakness and almost a certainty of its breaking by reason of the internal shrinkage strains. It is not the excess of metal in itself which gives rise to these strains, but the position in which it is placed relatively to other sections. Thus a lump of metal cast in juxtaposition to a thinner portion will not break the latter, so long as it is able to shrink freely upon itself. But if placed between two thinner portions, it may fracture them by its shrinkage. Hence the great aim is to so design castings that all portions thereof shall cool down with approximate uniformity. A founder learns much from the behaviour of cast iron pulleys and light wheels. As they are so light and weak, proportioning must be correctly observed, and when customers ask for a "good strong boss" or "strong arms," the request is one which, if complied with in the manner desired, that is, by unduly increasing the metal, will either fracture the pulley or wheel, or bring it near to the breaking limit. In all castings "strong" is a relative term, that form or size being strongest which harmonises as regards general proportions. In a light pulley three different conditions may exist: (1) All parts may cool down alike or nearly so; (2) the rim may cool long before the arms and boss; (3) the arms and boss may cool before the rim. In the first case, the pulley will be strong and safe. In the second, the rim in cooling will set rigidly, but the arms and boss will continue shrinking, each arm exerting an inward pull on the rim, and various results may follow. First, the strain may simply cause the arm to straighten, as shown by the dotted lines in Fig. 105. Or in less favourable conditions, and especially if straight arms, or arms but slightly curved, be used, the arms may fracture near the rim, but seldom near the boss. Or if the rim be weaker than the arms, fracture will take place as shown in Fig. 106. Or the pulley may be turned and then break, as shown in Fig. 107. In the third case, the arms and boss cool-

Digitized by Google

ing before the rim, they are compressed by the shrinkage of the latter, and the arms may then become fractured if curved; or, if straight, may prevent the rim from coming inward, and so break it. In most cases fracture occurs from the mass of metal in the boss. As a single instructive example out of many, I may quote that of a pair of 2ft. 6in. pulleys, fast and loose, which had been running for several years. The fast pulley had a boss 6in. in diameter, the loose pulley one of 5in. only, and both were bored to 3in. By the accidental falling of a bar of iron both were broken. The rim of the fast pulley at once assumed the position shown in Fig. 107, being pulled in, while the loose pulley remained level at the point of fracture. This illustrates the presence of tension in the rim, due to the larger boss, and this tension had been present since the pulley was made. The pulley with the 5in. boss was probably much stronger than that with the 6in. boss. In fast pulleys and in wheels keyed on, the necessary strength around the keyway may be obtained by the use of keyway bosses, without increasing the entire diameter. Where large bosses are unavoidable, as in some deep double armed pulleys, or in spur wheels keyed on to large shafts, shrinkage is assisted by opening out the mould around the bosses, and removing the central core, thereby accelerating the radiation of heat, and further by cooling them with water from a swab brush when at a low red or black heat. Many a casting is saved in this way. Another method is to split the boss with plates, and bond or bolt it together afterwards. When casting fly wheels with wrought iron arms, the rim is first cast around the arms, and allowed to cool nearly down before the boss is poured. If the latter were cast at the same time as the rim it would set first, and, by preventing the arms from coming inwards, would put tension upon the rim.

Where aggregations of metal occur in castings, they may, if the castings be too strong to fracture, cause an evil of a secondary character, known as "drawing;" in other words, the metal is put into a condition of internal stress, and becomes open and spongy in consequence. "Feeding" tends to diminish this evil; but much can often be done by lightening the metal with cores, chambering out, or reducing the metal massed in certain places by other means. There is a difference in the behaviour of cast iron and of gun metal, of which advantage may be taken in small light castings. Designs which will not stand in cast iron or steel, will stand in gun metal, hence the latter may be useful in cases of difficulty.

Sharp angles very often lead to fracture. The difference in strength between the large and small hollows in Fig. 108 would be probably equivalent to five or six times the amount of metal in the larger hollow distributed over the surface area of a casting, for the actual amount of metal in a hollow is very small. When brackets, ribs, lugs, &c., are cast on work, the corners should never be left square or angular, for if there be much disproportion of metal, fracture will almost certainly commence in the angles. The use of hollows, though apparently so simple, is really of vital importance.

I have already alluded to the "straining" which large plated and heavy castings undergo, so that the sides and faces increase in dimensions, becoming also more or less rounded. The plate (Fig. 96), 3ft. 6in. wide, was, when cast, $\frac{3}{8}$in. wider in the middle than at the ends, and the face, crosswise, was $\frac{1}{4}$in. rounded, notwithstanding that the face was cast downwards. The same thing is always more or less noticeable in frames of the type illustrated on page 268, Vol. III. (Fig. 25). This may be due partly to the resistance of the cores enclosed by the sides; but the main reason is, I think, that the metal round the central portions does not cool so rapidly as that at the sides. The outsides radiate heat quickly, and shrink to their full extent; but the middle rib or ribs and the central portions of the plate retain their heat longer, and hold the sides in a condition of tension, thus forcing them to bulge or become round. When the central portions cool, the outsides are too rigid to yield to the inward pull. This refers to framed hollow work. When plates "gather" or increase in thickness, this is due mainly to the lifting of the cope, due to insufficient weighting. When a cubical mass of metal shows no shrinkage, this is due to the pressure of the entire mass compressing the sand on every side.

Briefly stated then, in deciding the proper contraction allowance for a pattern, I should take into consideration its mass, the manner in which it is moulded and cast, the presence or absence of cores, and the nature of the same, its general outline, and the character of the metal. For a heavy solid casting in iron, I should allow considerably less than the normal contraction for iron; for a similar casting in steel, more than the normal contraction for steel; for a heavy casting in gun metal, less than the normal contraction for gun metal. The precise allowance in any case must be regulated by circumstances. For the vertical depth of a shallow casting, very little shrinkage, if any, should be allowed; for a deep casting, the full amount. Then again, a mould with dry sand cores of moderate or large size will not allow the casting to shrink so much as if the cores were of green sand, or were altogether absent. For hard and chilled iron, the shrinkage will be at its maximum; for strong mottled iron, at its minimum; and for common grey metal, at about the average.

(To be continued.)

IMPROVED DISCS FOR HEATING AND COOLING PURPOSES.

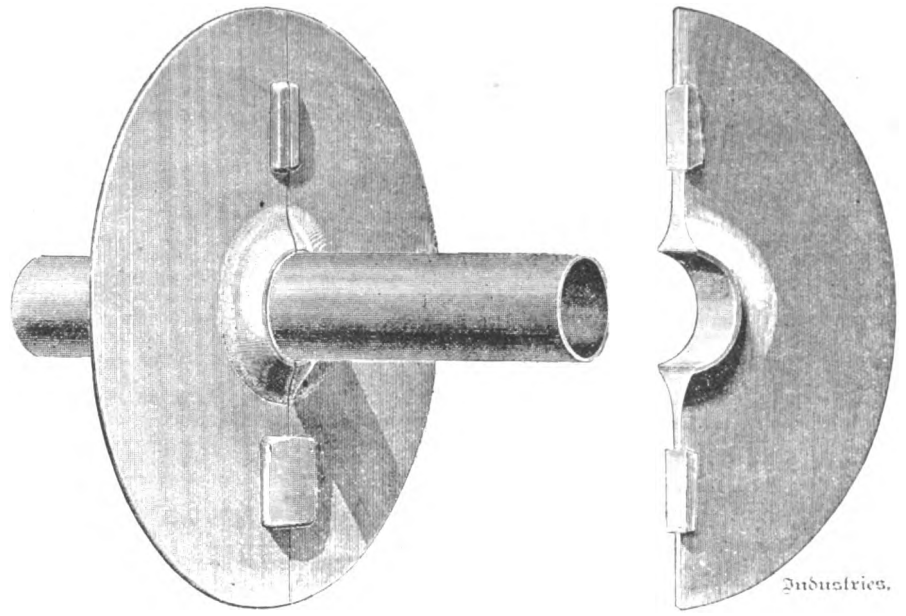

Fig. 1. Fig. 2.

IMPROVED DISCS FOR HEATING AND COOLING PURPOSES.

We are indebted to our American contemporary, *The Iron Age*, for the accompanying illustrations representing an improved form of "gills" or discs, which are intended for attaching to pipes in order to increase their cooling or heating surface. Fig. 1 represents the disc attached to the pipe, while in Fig. 2 half of the disc is shown detached from the pipe. The connection between the two halves is made in the following manner: On each half disc lugs are cast on, which project laterally on both sides, and have slightly inclined sides. When the two parts are put together, as shown in Fig. 1, these lugs correspond exactly, and by slipping an iron cap over each pair of lugs, as shown in the lower part of Fig. 1, a firm connection is effected. The pressure which may be exerted by means of the wedge-shaped lugs and caps is sufficient to keep the discs in position on the pipes. The efficiency of these discs is shown by the fact mentioned by the De La Vergne Refrigerating Machine Company, that by applying them to the cooling pipes, one lineal foot of pipe is now sufficient instead of 4ft. formerly necessary. A corresponding effect may of course be obtained in increasing the heating surface of pipes. We understand that these discs are made in three sizes, two round ones of 10in. and 14in. diam. respectively, and one of oval shape 10in. by 5in., in order to accommodate them to the space available.

THE DYNAMITE GUN.

Lieutenant A. H. Woolley-Dod, R.A., contributed to the Proceedings of the R.A. Institution an interesting paper on the pneumatic dynamite torpedo gun. A full description of this gun and its successful trial last year will be found in this paper, together with some general remarks which are of interest at the present time. It is pointed out that the gun is now a smooth bore, and the projectile is so long and so low in density that, according to Professor Greenhill's formula, the very rapid twist of one turn in 11 calibres would be required if rifling were attempted. This would severely try the thin walls of both shell and gun, added to which the high angular velocity would give an additional shock to the bursting charge, and the heat developed by friction would be a source of danger. Notwithstanding these difficulties, experiments are to be carried out to see how far rifling is possible. An interesting account is given of the electrical firing arrangements substituted for the percussion fuses which had at first been tried, but with unsatisfactory results. There are two batteries in each shell, one a wet one which is kept charged, the other a dry one, brought into action by being moistened. They are joined in series in a circuit in which is also included a piece of fine platinum wire, surrounded by gunpowder. The wire is placed at one end of a cylindrical capsule, the other end of which contains fulminate of mercury. The detonation of the latter detonates a cone of dynamite, which communicates its detonation to the main charge of gelatine containing 92 per cent. nitro-glycerine and 8 per cent. gun cotton. The circuit which is open during the flight of the shell is closed, on impact against a ship, by a projecting pin in the point of the shell, and the time between impact and detonation is regulated by the length of the column of gunpowder in the capsule. The wet battery is here the igniting agent. If the shell falls in the water, the dry battery is so arranged that the circuit is closed by being moistened by the water which is admitted to the battery through holes in the head of the projectile. By making these waterways more or less devious, as well as by designing the battery so that either a single drop or else a large quantity of water is required to complete the circuit, two other elements of delay, in bursting, may be introduced. According to Lieutenant Woolley-Dod, this gun should be compared, not with ordinary guns, but with torpedoes, as the object of the gun is not to obtain penetration, but to convey a large charge of violent explosive to a considerable distance, and there to detonate it. The dynamite gun has a great advantage, not only over the short ranging Whitehead torpedoes, but also over dirigible torpedoes, such as the Lay-Patrick, the Sims, and the Brennan. The maximum speed of these three is twenty-two miles an hour; they are all dependent for their action and accuracy on a long wire attached to the firing station, and they are steered by observation, which at ranges over one mile must be very difficult, except in a calm sea. They are all bulky; their cost is considerable, at least £1,500, and the proportion of weight of explosive to weight of torpedo is not one-tenth. It is also possible to avoid them by manœuvring, or to stop them by netting. The projectile from the dynamite gun, on the other hand, has a mean velocity of three hundred knots an hour; it can be fixed with accuracy at any range up to two thousand yards; it is comparatively light and inexpensive; and the proportion of bursting charge to weight of shell is greater than one-third. It can also be made to carry as large a charge as a torpedo. These projectiles are effective against the above-water portions of a ship as well as the submerged parts, and they cannot be evaded by manœuvring or netting. In studying this paper one cannot help being struck by the large field there is for a gun of this kind in protecting our great commercial ports, whose state of defence at the present time leaves much to be desired.

Metallic Shoe Soles.—A Nuremburg inventor has produced a shoe sole composed of wire net overlaid with a substance resembling india-rubber. These soles, which cost but half the price of leather, have been tested in the German army, and found to be twice as durable.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 6TH MARCH, 1888.

THE IRON MARKET.—Business in the iron trade has been slightly checked by a combination of circumstances. The heavy snows of the last two weeks have delayed building operations at the moment when fresh orders were about to be given out. The negotiations with Italy for the prolongation of the treaty of commerce have fallen through; and there is an uneasy feeling in the money market, occasioned, it is said, by apprehensions concerning the fate of the Panama Canal scheme. But though the market has shown less life, prices have remained very firm. The latest news from the provinces is encouraging. In the North, the trade in finished iron gradually acquires more life and vigour. The situation is improving in the Ardennes, where founders are especially busy. The crude iron trade of the Meurthe-et-Moselle grows more animated. The scarcity of pig in Belgium has occasioned a demand for foreign produce that has greatly benefited the Longwy district. Forge pig is very firm in price, but foundry is a little weak.

APPREHENDED FINANCIAL CRISIS.—An uneasy feeling pervades the commercial world, arising from the apprehension of impending disaster. A gigantic financial crisis is expected in consequence of what is now regarded as the inevitable and speedy collapse of the Panama Canal scheme. The uncertainty of the situation arising from this cause, and from the altered commercial relations with Italy, tends to disorganise the markets and to obstruct the flow of trade.

THE CYCLE MAKING INDUSTRY.—An effort is being made to establish at Saint Etienne large and complete works for the manufacture of cycles. Hitherto bicycles and tricycles have been imported from England and Germany; but the trade having grown to great importance an enterprising firm of engineers have resolved to establish this industry in France.

COMMERCIAL RELATIONS WITH ITALY.—The war of tariffs between France and Italy has broken out, and the conflict is regarded with enthusiasm on this side of the Alps. That the enthusiasm is of a spurious sort goes without saying, since there is obviously nothing to gain and much to lose in the struggle; but a sort of wild joy is affected here at the prospect of dealing injury to Italy through her trade. Time will probably make the cost severely felt, and dispel some of the glory which now surrounds the enterprise. The new retaliatory tariff has been voted by the Legislature with a precipitancy that reveals the existence of very unfriendly feelings towards our Italian neighbours. This state of things, which is conducive to the restriction of trade between Italy and France, will afford our German rivals an opportunity of which they will readily avail themselves.

A FRANCO-GERMAN CUSTOMS UNION.—Count de Leusse, a former Deputy, has published a pamphlet, in which he propounds a question, not yet, perhaps, within the range of practical politics, but interesting from its suggestiveness. He proposes to restore and preserve peace between France and Germany by uniting them in a community of commercial and industrial interests. His scheme, which originated, it is said, with the Crown Prince, is to create a Customs Union, embracing, in the first instance, France and Germany, but designed ultimately to absorb Belgium, Switzerland, Holland, Austria, and possibly Italy and Spain. In this way, says the author, we should form a great home market, sufficiently extensive to be self sufficing and capable of defending itself against over-sea competition.

BERLIN, 5TH MARCH, 1888.

THE IRON MARKET.—Although no change has as yet taken place in the demand for crude iron in the Upper Silesian district, some of the blast furnace owners begin to doubt whether the present exceptionally brisk trade will continue, and they evince a disposition to make concessions to consumers in order to secure orders ahead. On the whole, the prospect is still fairly good, which is partly due to the hopes raised by the budget. It is estimated that about £1,000,000 worth of work required for the army will directly or indirectly benefit the iron trade, whilst the State railways will during the year require a further equipment of railway material and rolling stock, which may roughly be estimated at £5,000,000. The railway budget last year amounted to £3,600,000, a large portion of which sum has yet to be expended, so that the railways will keep the iron trade fairly well employed for at least two years to come. According to statistics just published, the total production of crude iron throughout Germany —including Luxembourg—during January amounted to 346,962 tons, of which 177,321 tons were puddled and spiegel iron, 31,213 tons were Bessemer iron, 102,779 tons Thomas iron, and 35,649 tons foundry pig. The Dortmund Union have considerably extended their business by the purchase of the Victoria mine, near Porta, and of the new Wohlverwahrt mine, near Bückeburg. Both mines contain a good quality of red ironstone, and thus assure a cheap raw material to the Union. The fourth blast furnace recently erected at these works will be blown in shortly. At a recent competition for the supply of 1000 tons of ingot iron railway sleepers for the Würtemberg State railways, Messrs. Stumm Brothers, of Neunkirchen, obtained the contract at 131s. per ton, delivered free at Heilbronn. The Dortmund Union and the Rhenish Steel Works quoted 135s., and the Hörde Company 134s. Messrs. Stumm Brothers quoted 122s. at their works.

TEXTILES.—Jute spinners are fairly well employed, and prices have during the past month been repeatedly raised in sympathy with the foreign markets. Business in knitted goods is also satisfactory, and there is a good demand, especially for the cheaper kinds. In hosiery a fair number of orders, especially for better qualities for export, has been received. In tricots the demand is good, but prices are still depressed. As, however, the prices of yarn are steadily rising, it is confidently expected the tricots will also improve shortly.

BABCOCK & WILCOX BOILERS IN GERMANY.—Mr. Knight, the manager of the Babcock & Wilcox Company, of Glasgow, who are represented in this town by Herr L. Jahn, has made a contract with the works formerly known as Schwartzkopf & Co., of this town, under which the latter company will manufacture Babcock & Wilcox boilers on payment of a royalty. As reported a fortnight ago, these boilers were hitherto manufactured in Germany by Messrs. Schmidt, of Küstrin.

EXHIBITION OF SAFETY APPLIANCES.—It is proposed to hold next year in Berlin an exhibition of appliances for insuring safety to life and limb in manufacturing operations. One of the objects of the Exhibition is to bring about such legislative changes as will tend to the greater safety of workmen. The promoters have already organised sixteen separate committees, which will deal with the following branches of the subject: I., Safety appliances on moving machinery generally, coupling gear, winding machinery, &c.; II., appliances for use with motors and boilers; III., fire risk in artificial lighting; IV., safety appliances against poisonous gases, liquids, &c., and wearing apparel for the purpose. Committees V. to XII. deal with safety appliances to be used in the following trades; Metals, wood working, textiles, paper and leather, articles of food, chemicals, glass and pottery, mining and quarrying, and building. Committees XIII. and XIV. deal with safety appliances for traffic on land and water; XV. deals with agriculture and forestry; whilst XVI. is charged with collecting, arranging, and classifying the literature on the subject. Prospectuses and regulations may be obtained post free from the director of the Exhibition, Herr Max Schlesinger, Kochstrasse 3, Berlin. Applications for space must reach this gentleman not later than the 1st July.

VIENNA, 5TH MARCH, 1888.

THE COAL MARKET.—The coal market continues active. It is proposed to build a new railway line from Prague, *viâ* Kladno and Pilsen, and so open a short route between these towns and Bavaria and Southern Germany. This line will compete with the Western Railway of Bohemia, and it is expected by its establishment that a further impulse will be given to the Bohemian coal trade.

THE IRON MARKET.—No improvement in the condition of the crude iron market has taken place during the past week. On the one hand, Styrian works have to compete with coke-produced crude iron, which is cheaper; whilst on the other, the large stocks of the Hungarian State iron works, which have been thrown on the market, have a tendency to depress it. In Austria-Hungary there has been a greater demand this week for rolled iron and cast iron ware than has been experienced for two or three weeks. In consequence of the unfavourable season, iron for building purposes is not in very good request, and no increase in the price of girders has taken place; but some advance is expected in large sheets and tank plates. The quantity of bar iron now being sold in Bohemia is still unsatisfactory; but the demand for agricultural implements, and especially ploughshares, has increased. Large quantities of agricultural implements are being imported into Bohemia from Upper Silesia notwithstanding the import duty, and these goods compete very keenly with the same kind of articles manufactured in Styria. A fair demand exists for galvanised and tinned sheets, and also for black sheets.

TEXTILES.—In former years a good spring business has been the rule at this period; but this year everything is quiet, and orders for the spring have not yet been placed. Buyers from Hungary and Galicia are expected to come into the market during the present month, which will cause a slight revival. In cloth and millinery goods there is a tendency to copy English striped patterns. Owing to increased import tariffs, German competition in worsteds is somewhat less keen at the present moment, and Austrian makers have now a chance of increasing this trade. It is, however, somewhat unfortunate that the reputation of this article as made here is not very high, so that it is difficult to do an export trade. The war of tariffs with Roumania has almost completely paralysed the export business to that country, and to overcome this difficulty some Austrian spinners and weavers have recently sent goods to Roumania by way of Germany; but their German rivals have petitioned their Government to take steps to prevent this practice. The German Government has not interfered; but the publicity thus given has had the effect of throwing considerable difficulties in the way of Austrian exporters.

SHIPPING IN TRIESTE.—Statistics on the trade of the port of Trieste during the last year have just been published. During that year a total of 4369 sailing vessels, representing 212,785 tons, and 3664 steamers, representing 1,172,092 tons, entered the port. The total number of vessels is therefore 8033, and the total tonnage 1,384,877 tons, as compared with the previous year, when the figures were 6806 vessels, with a total tonnage of 1,151,708 tons. The majority of vessels trading from the port of Trieste sailed under the Austrian flag. Amongst these were 2685 sailing vessels, representing 88,226 tons, and 3103 steamers, representing 696,254 tons. During the year 8128 vessels cleared the port, of which 4450 were sailing vessels, and 3678 were steamers, the total tonnage amounting to 1,393,524 tons.

BRUSSELS, 6TH MARCH, 1888.

THE COAL MARKET.—There is a good sale at remunerative rates, and coke is very scarce, in consequence of the large demand on the part of blast furnaces. Coal for metallurgical purposes is firm, the time for the renewal of contracts being near. The outlook in the Charleroi district is decidedly favourable, in spite of the stoppage of canal traffic and the scarcity of railway waggons, while at Liège there is a constant demand from French sources.

THE IRON MARKET.—Foundry pig continues dear. Rolling mills and engineering works are well employed. There is a good demand for sheets and special sections in spite of the threatened war of tariffs with Italy. There is a number of orders for rails from America; but still the steel works of the Centre and Liège are not so busy as they might be. Cockerill is not supplied with constant work, and Selessin has been disturbed by an explosion. La Meuse and St. Leonard works are well supplied with orders, the former now being engaged in locomotive building. The Hoboken shipbuilding yard, near Antwerp, is busy; but M. Beer, of the Jemeppe yard, is not doing much. Contracts will shortly be given out for metallic roofing in connection with the extension of the Malines Arsenal.

TELEPHONY.—Yesterday the following means of telephonic communication were opened between Brussels and Paris: (1) Between the subscribers and exchanges on the Brussels system on the one part, and the public call offices at the Paris Exchange on the other; (2) between the subscribers and exchanges on the Paris system, and the public call offices at the Brussels Exchange; (3) between the private establishments and public offices of Brussels which have secondary wires to the exchanges on the one part, and the subscribers to the Paris Exchange at Paris on the other. Experience has shown the necessity of using a complete metallic circuit at Brussels in order to obtain satisfactory communication with Paris.

THE VAN RYSSELBERGHE TELEPHONE SYSTEM.—This system is to be adopted for a number of lines in Japan, and an order has been received by Messrs. Mourlon Frères, of Brussels, for all the material necessary to fit up one of the principal telegraph lines in that country for telephonic communication. A similar order has been given to the same firm by the Bolivian Government. The railways of Greece are also going to apply the system for communication between the various signal boxes on their lines.

THE EXHIBITION.—The buildings of the English section are being rapidly erected, and occupy about 50,000 sq. ft. The machinery section only requires to be covered in, and the annexes will be immediately commenced. In the latter case material from the Antwerp Exhibition will be used. The masonry of the horseshoe building is finished, and the iron work is being proceeded with. The frost has delayed work a good deal, and should it continue the date of opening will have to be postponed. The machinery section will be comparatively unimportant, and metallurgical works will be poorly represented. One of the most interesting portions of the Exhibition will be the electrical department.

GAS LIGHTING.—The Society of Belgian Gas Engineers are raising funds for a permanent exhibition of gas lighting and heating appliances, which will be on a larger scale than that which was promoted by the town. It is proposed that experiments should be made with new inventions; but as the arrangements are in the hands of a certain ring, it is doubtful whether this portion of the scheme will prove a success, as inventors and makers of special apparatus may not care to submit their productions to the judgment of possible rivals. A new gas lamp is being introduced here which consists of the following parts: A regenerator carrying the burner and distributing the hot air both inside and outside the flame, a burner of the Argand type connected with the gas supply pipe, the frame work of the lamp carrying the chimney, and a globe which is fastened to the regenerator so as to prevent the admission of cold air from outside. This lamp is not influenced by currents of air, and gives a white and agreeable light. It is claimed for it that its efficiency is higher than that of regenerative lamps with inverted flame.

DÜSSELDORF, 5TH MARCH, 1888.

THE IRON MARKET.—The external aspect of the iron market remains unaltered. Pig iron of all sorts is in brisk demand, and prices are very firm. But if we search beneath the surface, we find influences at work to bring to a speedy end the period of activity through which we have been passing. The extreme animation of the market has been largely due to speculative buying occasioned by the syndicating of the trade, and the consequent successive and easily foreseen advances in the prices of all classes of iron goods. The high level to which prices have now been forced begins to tell so heavily upon the demand for consumption, both at home and abroad, that speculators

Digitized by Google

are not likely to push their operations much further. The production of pig iron has nearly reached the highest attainable point, and though hitherto the demand has kept pace with the supply, it is, partly for the reason just stated, and partly owing to the constant shrinkage of the export trade, likely to decrease soon. The make of pig in January averaged 11,192 tons a day, against 11,608 tons in December. This falling off has, however, no significance, being attributable to the New Year holiday season. The tendency of business to shrink in the immediate future is indicated by the languor in merchant bars which is beginning to show itself in the trade. The full capacity of the works may be assumed at a monthly output of 24,000 tons, but the fresh orders booked in the first two months of the year scarcely exceeded 20,000 tons. The blast furnace owners have under consideration a proposal to sell pig at a reduced rate to makers of finished iron and steel who can show that it is required for the execution of foreign orders. To such straits has the artificial system of syndicates brought us! What relief this will afford remains to be seen.

Migration of the Crude Iron Industry.—A recent article appeared in *Industries* directing attention to the fact that under the present conditions of smelting it is advantageous to transport the fuel rather than the ore. The same idea has taken root here in a scheme for transferring the blast furnace industry of the Lower Rhine and Westphalia to Lorraine, the "Minette" ore district, whence the furnaces now derive their supplies of ore. Efforts are being made to obtain a reduction in the railway rates for the carriage of this ore; but it is urged in support of the new scheme that as about two tons of ore are needed to yield one ton of pig, it would be advantageous to carry one ton or less of coke to furnaces erected at the iron mines. A simple calculation shows that the cost of transporting the coke to the mines and conveying the pig iron back to the Rhenish-Westphalian finished iron works would amount to only about three-fourths of the present cost.

The Yarn Market.—The demand for tow yarns continues brisk for all numbers. Flax yarns are more inquired after; but though important dealings in the latter have taken place within the past few days, spinners still complain of the insufficiency of demand. Prices are moreover at too low a level.

LILLE, 6th March, 1888.

Textile Manufactures.—The failure of the negotiations with Italy, and the prospect of a war of tariffs between that country and France, has considerably disturbed the textile manufacturing industries of this locality. The loss of the Italian markets must seriously curtail our export trade, and delay the revival which seemed about to take place. The influence of this untoward event has damped the spirit of the woollen market at Roubaix, and occasioned little short of a panic in the silk goods trade of Lyons. The outlook is discouraging, and for the moment a tone of despondency prevails. These depressing influences apart, the situation shows some improvement. There is more activity in linen goods, and a better demand is springing up for cotton fabrics. The spinning industry is getting upon a better footing. Cotton yarns are in fairly strong demand, at the more remunerative prices which are now current, and flax spinners have plenty of work in hand. The wool spring trade is in a very unsatisfactory state.

Flax and Yarn Markets.—The demand for home grown flax is unabated, but the supply is running short. This circumstance has given an upward tendency to prices. The low rate of exchange has led to large purchases of Russian flax. Tows are quiet for home consumption; but some heavy dealings have taken place for export. Linen yarns are still in good demand, prices being very firm. Jute yarns are still much sought after. The Ghent markets are less active, both for raw flax and for yarns; but prices have not given way.

The Iron Market.—The iron market has developed no new feature since my last report. A steady progress towards recovery is being made. Business has been hindered by the wintry weather of the past two weeks, but there is no lack of fresh orders. The demand for plates continues very brisk. Perfect unity of aim and action having been established between the manufacturers of this locality and those of the Centre, prices now rest upon a firm basis.

WINTERTHUR, 5th March, 1888.

Engineering Trades.—Messrs. Sulzer Brothers, of this town, have turned out their thousandth valve engine. These engines were first made here twenty years ago, from the designs of an English engineer, Mr. Brown, and have since found a very ready sale. Messrs. Sulzer have lately used them largely in combination with the Linde refrigerating machines made by them, in which they do an export trade to Africa, Asia, and South America. Messrs. Escher, Wyss, & Co., Zürich, are also making a specialty of refrigerators on the Windhausen system. In this machine the working fluid is carbonic acid.

Paper Making.—A new kind of paper for packing meat, butter, cheese, and other provisions, has been brought out by Messrs. Robert Bareiss & Co., of Balsthal, Solothurn, under the name of parchment paper. It is made from chemically prepared fibres, without any admixture of chlorine or other bleaching compound, or of any colouring matter. The paper is not weighted, and is to a great extent impermeable to water and oil. It neither sticks to the substance which it envelopes, changes its colour, nor leaves any smell.

A Works for the Manufacture of Preserves.—A fruit and vegetable preserving works is to be established at Lucerne, with a capital of £10,000. It appears from the Customs statistics that the annual imports of dried fruits have risen during the past twenty years from 220 tons to 3100 tons. The annual value of the imports, three-quarters of which come from Germany and Austria, is £80,000, and of the exports only £3,200, so that the new establishment will experience no difficulty in finding a market for its products.

MILAN, 5th March, 1888.

Italy's Foreign Trade.—Statistics giving the value of the imports and exports during the past year have recently been issued. The total value of the imports during 1887 was about £63,000,000, being an increase of £6,000,000 as compared with 1886. The exports during the past year are valued at only £39,000,000, showing a decrease of £5,500,000 as compared with 1886. The large difference of £24,000,000 between imports and exports is partly due to the fact that towards the latter end of the year importers found it prudent, in view of the new Customs tariff which came into force on the 1st January, to considerably increase their stocks beyond immediate requirements. The greatest activity in imports was shown in chemicals, linen yarns, raw cotton, and cotton piece goods; also in woollen cloth and silk piece goods. The effect of the new protective policy is very plainly seen in a rise of prices, varying for different commodities from 5 to 20 per cent., as compared with the ruling rates in December.

Electrical Engineering.—A contract has just been concluded between the Oerlikon works and a large woollen goods manufacturer near this town for the erection of an electrical plant capable of transmitting 250 h.p. over a distance of 550 yards, with a guaranteed efficiency of 78 per cent. Power is supplied by turbines at the generating station, where it will be used to actuate two Oerlikon dynamos coupled in series, and the current will be sent to the mill by three wires to the two motors at the mill in the same manner as was adopted in the Kriegstetten installation. The makers of the plant are confident that of the 250 h.p. transmitted to the spindles of the dynamos, 200 h.p. will be actually available at the mill.—Some trouble has been experienced in Milan with the Edison tubes. Owing to settlements in the ground and to the heavy traffic these were frequently broken, causing considerable leakage of current. The Electric Lighting Company are therefore taking up all the Edison tubes, and are re-laying the conductor in wooden troughs with insulation.

MADRID, 5th March, 1888.

Railways.—Tenders are invited for a line to connect Algeciras with the Andalusian railway system, the last day for receiving the same being 14th May. A subvention of about £440,000 is offered by the Government, and the business is almost certain to fall into the hands of an English company, the promoters of which have already made preliminary surveys. In this case, as in most other Spanish railways, there should be a profit, provided that the cost of construction is kept within reasonable limits, and that the financing of the scheme is sound. A concession is asked from the Government for the construction of a one-metre gauge railway from Oviedo to Infiesto, Asturias. The length of line will be thirty miles, and the estimated cost of construction £83,000. It is expected to pay a dividend of 10 per cent.

The Barcelona Exhibition.—This Exhibition now seems likely to be successful. Applications have been received for more space than is available, and the work is being rapidly pushed forward.

Spanish Shipbuilding.—There are at least two shipbuilding yards to be established at Bilbao—one by Señor Martinez de las Rivas in connection with Sir Charles Palmer, and the other in connection with the new company registered in London, with which Lord Brassey is associated. Great interest is manifested in marine and industrial circles as to which of the two will receive the first contracts from the Government. As far as the three cruisers are concerned, I should say they will be placed with that yard which is the more Spanish in its constitution. The chances appear to be in favour of the former of the two, owing to the high reputation of Señor Martinez de las Rivas as a man of business, and to Sir Charles Palmer being well known as a shipbuilder. Very little is expected from a third yard which is to be established by La Viscaya Blast Furnace Company in connection with the French Gironde Company.

NEW YORK, 25th February, 1888.

The Iron and Steel Market.—The settlement of the miners' strike, though advantageous for the company and the miners, will have a depressing influence both on the coal and the iron trade. The Wyoming district has been sending into the market as much coal as was sent last year from all the anthracite coal fields. Some furnaces will now be able to make cheaper and better iron; but the demand is not likely to rise, and the fact that customers could buy their iron with no advance in price while the strike was on will make them feel now it is over that they certainly ought to have some reduction. As sellers are beginning to feel anxious for business, there is but little chance of a firm market. In the pig iron market at present the supply is greater than the demand, and the rates are sure to come down. With the exception of a few large orders, business in manufactured iron is dull. Prices are nominally 2 cents per lb., but for important orders discounts amounting from 10 to 15 cents per 100lb. are given. Some mills are closed entirely, while the majority are running about three-quarters time. The steel rail market continues firm, and the prospects for an increasing demand are very good. A liberal amount of orders has been entered during the past week with nothing below $31·50 per ton at the mill.

The Metal Market.—The copper market has been dull, with no change in price. The tin market is very quiet. There have been only a few inquiries for lead, except for speculation, and it is doubtful if the present prices will hold unless the demand increases.

The Nail Trade.—The effects of the great nail makers' combination in the East is making itself felt in the Western district. The estimated production throughout the States is nearly 1,000,000 kegs, of which 550,000 are made by the Eastern Association, and 340,000 by the Western Association.

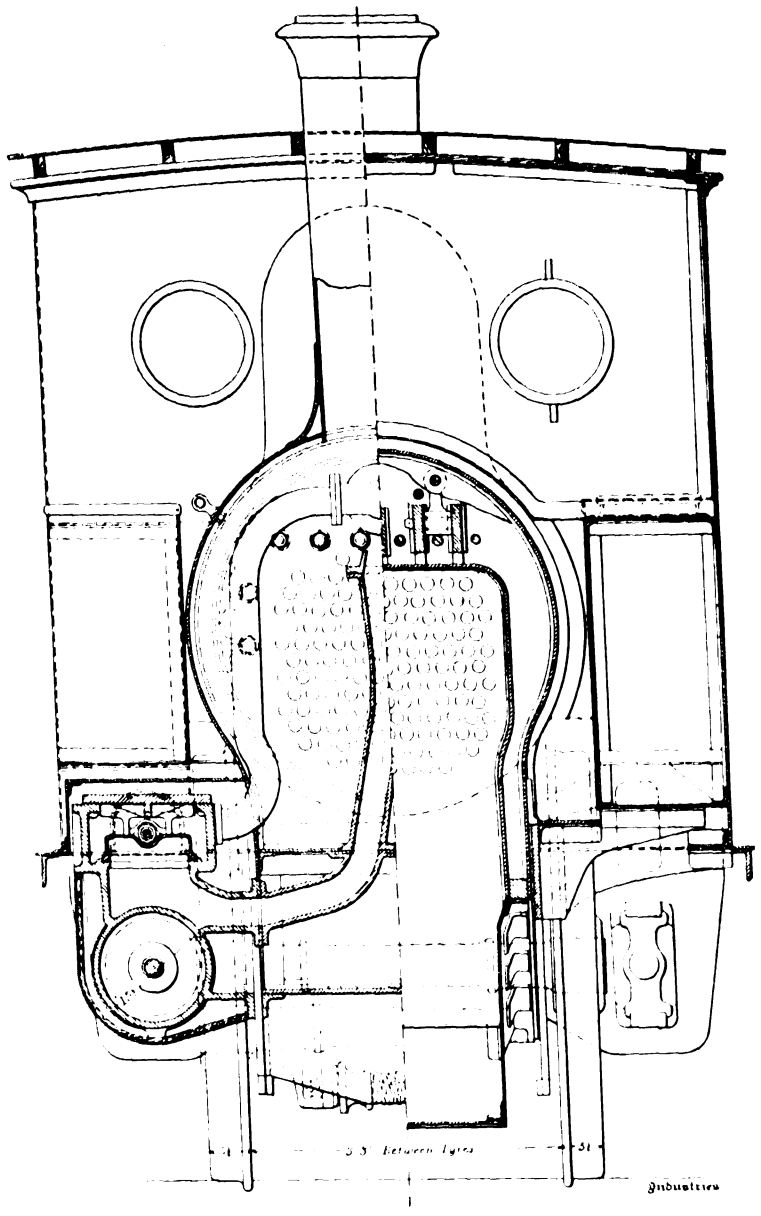
Electromotors.—The use of electromotors, where considerable power is required, is becoming more common, and the demand exceeds the supply for motors to replace steam or gas engines in the smaller manufacturing establishments. Until within the last few months, Messrs. Van den Houten & Co., of New York, have used a 10 h.p. steam engine to drive the presses in their printing establishment. The steam was supplied by the mains, but the service was so bad that it was determined to try electricity. A 7½ h.p. (rated) Sprague motor was procured, and has been doing all the work required without interruption. It drives four large Gordon cylinder presses, and three Gordon job presses, with ease.

Lighthouse Lens.—The largest lens ever brought to this country will be placed in the Sandyhook Lighthouse. It has been made in Paris, at a cost of £3,000, and is 15ft. in height, the internal diameter being 8ft. It is of the hyper-radiant type.

Cast Steel Gun.—The boring of the new large cast steel gun has now been completed. A flat drill, which had to be sharpened after every 9in. bored, was used. The total distance bored was 193·5in. The grain of the steel has been found to be remarkably uniform. The gun will now be turned on the outside, after which it will be sent to Washington to be rifled and tested. About 1200lb. of cuttings have been bored out by the drill.

PHILADELPHIA, 25th February, 1888.

Tunnel Lighting by Electricity.—Workmen are *engaged* in putting the Westinghouse converter system of electric lighting into the Hoosac Tunnel. Owing to frost, the work of laying the wires has been considerably delayed. The conduits are of ¾in. Canadian pine, seasoned three years, soaked in a composition of tar and oil, and painted with tar outside, before laying in the trench. About sixty miles of wire will be used for mains and lamp connections. There are to be 1250 25-c.p. lamps fixed to the side walls of the tunnel, 6ft. above the top of the rails. Metallic parts on the lamps are avoided as much as possible, or securely protected from the bad effects of the sulphurous gases and moisture. It will be some time before the work is finished, although the time stipulated in the contract is already past.



Steel Car Wheels.—The Pittsburg Steel Casting Company has been making some steel car wheels by a new process. While the metal is cooling the moulds are quickly rotated to compress the material in the rim, and so strengthen it. The wheels are said to be very strong and durable, and much lighter than the paper wheels. They are selling at 4 cents per lb., which makes them more expensive than cast iron, but still very much cheaper than paper or built up steel wheels. After the wheels are cast they are re-heated, and rolled on the tread and flange until perfectly round, which process hardens the surface and reduces the wear on wheel and rails. The wheels successfully stand the test required by the Pennsylvania road.

Shipbuilding.—The steamer "Puritan," now being built at Chester, Pennsylvania, for the Fall River Line at a cost of £300,000, will be the largest vessel of her class afloat. The hull is of steel, 420ft. over all; 404ft. on the water line; beam, 52ft., and 91ft. over the guards. She will draw 12ft. of water. Her gross tonnage is estimated at 4650, and displacement 4200 tons. The engines are to be vertical beam compound, with cylinders 75in. by 9ft., and 110in. by 14ft. The boilers are to be of steel, of the return tubular type, to stand 110lb. per square inch. The horse power is to be 7500. Feathering paddles, 35ft. diam., are expected to drive the vessel at twenty-one miles per hour, by making twenty-four revolutions per minute.

Railway Bridges.—The necessity of governmental supervision of bridges is shown in a report of the Massachusetts Railroad Commission. The State law requires that plans of all such structures should be submitted to the commission; but it was found that many companies had no plans or strain sheets of many of their bridges, nor any definite knowledge of their condition. Unsuspected weakness was discovered on many of the roads, and steps are being taken to remedy the defects.

TANK LOCOMOTIVE FOR THE JAPANESE RAILWAYS.

END ELEVATION.

TANK LOCOMOTIVE FOR THE JAPANESE GOVERNMENT RAILWAYS.

We give above and on our two-page supplement for this week, and also on page 244, illustrations of one of a series of eight-wheel tank locomotives, built by Messrs. Nasmyth, Wilson, & Co., Limited, engineers, Patricroft, near Manchester, from the designs of Mr. F. H. Trevithick, M.Inst.C.E., locomotive superintendent for the Japanese Government Railways. It will be seen from our illustrations that the cylinders are 13½in. diam., and the stroke 20in. The coupled wheels are 51in. diam.—when the tyres are half worn—and carry a load of 17 tons 8¾cwt. when the engine is in full working order. The tractive force per pound of mean effective cylinder pressure is $\frac{13{\cdot}5^2 \times 20}{51} = 71{\cdot}5$lb., and the boiler pressure is 140lb. per square inch. The leading and trailing wheels are fitted with Mr. Webb's well known radial arrangement, by means of which the rigid wheel base is reduced to 7ft. 6in.—the distance between the centres of the coupled wheels. We understand that these engines have given great satisfaction both as regards steadiness of running and general capability for work.

THE TASMANIAN RAILWAYS.

The island of Tasmania, or Van Dieman's Land as it was formerly called, lies to the extreme south of Australia, between 40° 15′ and 43° 45′ south latitude, and between 144° 45′ and 148° 30′ east longitude. It is separated from Australia by Bass Strait, 120 miles wide; but it is in telegraphic communication with the Australian continent, and therefore with Europe, the Tasmanian and Victoria submarine telegraph being worked by the Eastern Extension Telegraph Company upon a guarantee from the Tasmanian Government. The greatest length of the island is 230 miles, and its greatest width 190 miles. Its surface is estimated at 26,215 square miles, or about 6000 square miles less than Ireland. The total area, exclusive of islands and lakes, is 15,571,500 acres, or inclusive of these, 16,778,000 acres. The population at the last census in 1881 was 115,705, and it is estimated to be now close on 140,000 persons. Tasmania is a mountainous country, having hills ranging from 1000ft. to 6000ft. in height. It has several extensive lakes on the high central tableland, and these form the sources of the chief rivers, of which there are several. The climate of Tasmania is very salubrious, and the island is recommended as a sanatorium for invalids, the hot north winds of Australia being tempered by the 120 miles of sea at Bass Strait. The chief products are tin and gold, wool, wheat, oats, barley, potatoes, timber, hops, fruit, jam, and whale oil. The Government of Tasmania, with a view to encourage special manufacturing industries, have offered bonuses from time to time, of which the following are yet unclaimed.

Sugar from beet or other products grown in the colony, bonus £2,000; 200 tons to be manufactured in one year.

Salt.—On 300 tons being manufactured in one year, a bonus of 10s. per ton for the first hundred tons, and 5s. per ton for the second and third hundred.

Corn Sacks or Woolpacks.—Bonus £1,000. The quantity of sacking suitable for working up into those articles turned out in one year to be 40,000 yards.

Up to about four years ago Tasmania was considered a sleepy colony, and was dependent upon Australia and England for the supply of most articles of general consumption. Now the country has awakened; trade is developing and railways are extending in various directions. During the past three years no less than 27 jetties have been erected. Better vessels are visiting the ports of the colony, and large and handsome warehouses and business establishments are being erected in the chief towns.

The first line constructed in Tasmania was the Launceston and Western Railway, connecting Launceston with Deloraine, 45 miles to the west. It was originally constructed by a private company, but eventually it fell into the hands of the Government. It is a substantial line, 5ft. 3in. gauge, and equipped in a superior manner. The other Government lines being all of 3ft. 6in. gauge, it was decided to mix the gauges, and a third line of rails was laid down about three years ago, and practically all traffic is now conducted over the 3ft. 6in. gauge. An extension was made on the 3ft. 6in. gauge from Deloraine to the river Mersey, a distance of 37 miles on the North-west Coast, passing through a mineral and agricultural country. The cost of construction to the end of 1885, including the Mersey extension, was £658,012, whilst the net revenue for the same year was £66,424. The main artery of communication through the colony runs nearly north and south, from sea to sea. It is known as the Tasmanian Main Line Railway, and is the property of a British company, and constructed under a Government guarantee of 5 per cent. per annum upon a capital of £650,000. This main line connects Hobart Town on the South Coast with Launceston on the North Coast, a distance of 133 miles. At Evandale the Main Line Railway has a junction with the Launceston and Western Railway, and with running powers over it. The cost of construction and equipment of the Main Line Railway was £1,182,352.

The other Government lines completed or in course of construction are: (1) The Fingal Railway, from Corners Station on the main line to St. Mary's on the East Coast, a distance of 47 miles. This line passes through an agricultural country, and opens up the coal fields of Mount Nicholas in the vicinity of St. Mary's. (2) The Parattah and Oatlands Railway, 4¼ miles long, connecting the township of Oatlands with the main line. The cost of construction was £10,249. This railway belongs to the class of light lines, and is worked by a single engine and carriage. (3) The Derwent Valley line, 24¼ miles long, from Bridgewater, near Hobart, to Glenora. The estimated cost is £140,000. The contract for its construction was let to Mr. J. Falkingham, of Melbourne. In consequence, however, of the unsatisfactory rate of progress, the contract was terminated by mutual consent, and the work completed by the Government. In connection with this railway, it was decided that the whole of the wrought iron cylinders and girders required for the large bridge over the river Derwent should be manufactured locally. The engineer, in reporting upon the progress of the work, stated that it was an advantage so far as encouragement was given to local enterprise; but he regretted the loss in time and money, which would otherwise have been avoided. (4) The Scottsdale line, from Launceston to Scottsdale, 47 miles long. The estimated cost is £300,000, and the contractors are Messrs. Boland & Scott, of Launceston. (5) The Tullery Extension Railway, from Deloraine to Formby, 37¼ miles long. This railway it is proposed to extend to Ulverston, and ultimately as far as Emu Bay, and there join the Van Dieman Company's line.

The Van Dieman's Land Company's Railway or the Emu Bay Railway is a private line, and runs from Emu Bay, on the North Coast, to the Mount Bischoff Company's tin mines, 48 miles in the interior. The gauge is 3ft. 6in., the same as on the standard Government lines. This line runs through a densely timbered country, and has some sharp curves and steep inclines. Formerly it was merely a tramway for conveying tin from the mines to the coast. The rolling stock has been mostly constructed by the Bristol Waggon Company. The locomotives are adapted to burn wood, and are of the American type, and built by the Hunslet Engineering Company, Leeds. Besides the lines opened and in course of construction, the Government have sanctioned the Green Ponds Railway from Brighton Station, on the Main Line Railway, to Apsley, at an estimated cost of £106,500; the Sorell Railway, on the South Coast, from Bellerive to Sorell, at a cost of £61,800; the Chudleigh Railway, being a continuation of the Launceston and Deloraine line, from Chudleigh Road Station to Mole Creek, to cost £30,000; and the North-Western Railway from Formby to Ulverston, referred to above, which is estimated to cost £69,700. The Government have also authorised surveys for further lines, viz., from Kimberley's Ford *viâ* Sheffield to the Western Railway, 18 miles long, on the North-west Coast; Ulverston to Emu Bay, 17 miles long, already mentioned, from Tunack to Parattah station on the Main Line; Autill Ponds, to Cressy and Longford; Lower Piper branch, Scottsdale Railway, 14 miles; Glenora to the Ouse, 21 miles; Scottsdale to Upper Ringarooma, 23½ miles. The amount authorised for these surveys is £7,500, and according to the report of the engineer-in-chief (Mr. J. Fincham, M.Inst.C.E.), a good deal of the surveying work is already done, and the plans, sections, and working drawings necessary for contract, with lithographic copies of same, are nearly complete. Specifications and bills of quantities are prepared as far as possible, whilst particulars for contracts for rails have been prepared, and now are

Digitized by Google

in the hands of the Agent General in London. From the above it will be seen that the Government of Tasmania has a good deal of railway work either in hand or in prospect; and as railways are after all only a means for serving the trade of a country, it would seem that the Government is confident of a considerable expansion of the general trade of Tasmania. British manufacturers will, therefore, do well not to lose sight of what is being done in this small but relatively busy colony. Nearly the whole of the railway work now in hand has been initiated by the last Government, under the Premiership of the Hon. A. D. Douglass, Q.C., the former Agent General in England, and the Hon. Nicholas J. Brown, Minister of Public Works. The rails, locomotives, carriages, and other railway material were obtained from England.

SHIPBUILDING NOTES.

The lightest draught stern wheel passenger steamer ever built on the Mersey was launched from Messrs. James Taylor & Co.'s yard at Birkenhead, on the 29th ult. The "San Fernando" has been built to the order of Messrs. Japp & Kirby, of Liverpool, and has been specially designed for inland navigation in South America. The engines work at a steam pressure of 160lb. with an early cut-off, and the boiler is of very large proportions to suit the combustion of wood as fuel. The load draught of water is 18in.; the speed, 12 miles an hour; and the revolutions of the paddle, 62 per minute. The vessel is built entirely of steel, in segments for shipment; the length is 100ft.; breadth, 13ft. 6in.; depth of hold, 4ft.

On the 29th ult., Messrs. S. P. Austin & Son, Sunderland, launched a sailing vessel of the following dimensions; Length between perpendiculars, 235ft.; breadth moulded, 37ft.; depth of hold, 22ft. The vessel is constructed of Siemens-Martin steel, and will be fitted up with the latest improvements. It was built on speculation, and has been recently sold as a foreign order.

The Belgian Government has contracted for the construction of a second fast steamer for the mail traffic between Dover and Ostend. The steamer is to be built by Messrs. Denny & Brothers, Dumbarton, who have now in course of construction the first of the new fleet which the Belgian Government have determined to place on the English mail route.

On Tuesday afternoon was launched from the yard of the builders, Messrs. Raylton, Dixon, & Co., Middlesbrough, the steel screw steamer "Fulford," built to the order of Messrs. J. M. Lennard & Sons, of Middlesbrough. She is of the following dimensions: Length, 267ft.; breadth, 36ft.; and depth, 19ft. 6in.; and she will carry a dead weight of over 2500 tons. She is built on the well deck principle, with long bridge deck extending to foremast, and is in many respects a great improvement upon the last vessel built for the same firm, for whom Messrs. Raylton, Dixon, & Co. have already built six steamers. She will be fitted with triple expansion engines on the latest improved principle by Messrs. Blair & Co., Limited, Stockton.

On Tuesday last, Messrs. W. Gray & Co., West Hartlepool, launched a fine steel screw steamer of the following dimensions: 300ft. over all, 38ft. beam, and 22ft. 2in. depth, of 3500 tons dead weight capacity, built to the order of Messrs. T. Appleby & Co., West Hartlepool, and classed 100 A1 at Lloyd's. The vessel is of the well decked type, with poop aft, containing saloon and cabins for officers and a few passengers, long raised quarter deck, long bridge of extra strength right up to fore hatch, and containing comfortable quarters for the crew. The usual topgallant forecastle is fitted forward with Emerson, Walker, & Co.'s windlass. The hull is built on the web frame principle, dispensing with hold beams, and giving a clear hold for working cargo; five hatches are fitted, four steam winches, steam steering gear, and two donkey boilers; with double bottom under the holds for water ballast. The boats are carried on beams overhead. The vessel will in every respect be well equipped for general trading. The engines, which are on the three-cylinder triple expansion principle, are being supplied by Messrs. Blair & Co., Limited, Stockton-on-Tees. The vessel has been superintended during construction by Captain Baker, on behalf of the owners, and is the eighth vessel owned by Messrs. Appleby & Co. which has been built by W. Gray & Co.

On the 28th ult., Mr. James Laing, Deptford Shipyard, Sunderland, launched the finely modelled screw steamer "Ben Clune," built to the order of Messrs. John Morrison & Son, North Shields. The vessel has been constructed of Siemens-Martin steel, and has a raised quarterdeck, hurricane house from after end of engine room to foremast, and topgallant forecastle. Bracket frames are fitted in the lower holds. The principal dimensions are: Length between perpendiculars, 275ft.; breadth moulded, 38ft.; depth of hold, 20ft. 6in.; and the deadweight capacity, 3000 tons on a light draught. The vessel will be schooner rigged, and fitted with triple expansion engines of 180 n.h.p. by Mr. George Clark, Southwick Engine Works. This is the eleventh vessel constructed by Mr. James Laing for the same firm of ship owners.

TRAFFIC RETURNS.—The following are the receipts of the Great Northern Telegraph Company: February, 1888, £20,400; 1st January to 29th February, 1888, £41,800; corresponding months, 1887, £39,600; 1886, £38,680.

Notices of Meetings.

THIS WEEK.

SOCIETY OF ARTS.—Saturday, 10th March, 3 p.m. Dr. Mann lecture on the "Protection of Buildings from Lightning," by Professor Oliver J. Lodge, D.Sc., F.R.S.

PHYSICAL SOCIETY.—Saturday, 10th March, 3 p.m. Papers to be read on "A Reflecting Galvanometer," by Mr. G. L. Addenbroke, and on "A Theory Concerning the Sudden Loss of Magnetic Properties in Iron and Nickel at a High Temperature," by Mr. Herbert Tomlinson.

NEXT WEEK.

SOCIETY OF ARTS.—Monday, 12th March, 8 p.m. Cantor lecture on "Alloys," by Professor Chandler Roberts-Austen, F.R.S. —Wednesday, 14th March, 8 p.m. Ordinary meeting. Paper to be read on "Technical Instruction in Agriculture," by Professor John Wrightson.—Friday, 16th March, 8 p.m. Indian Section. Paper to be read on "The Origin, Progress, and Influence of Universities in India," by F. J. Mouat, M.D.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 13th March, 8 p.m. Ordinary meeting. Paper to be read with a view to discussion, "Economy Trials of a Non-condensing Steam Engine—Simple, Compound, and Triple," by Mr. P. W. Willans, M.Inst.C.E.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—Wednesday, 14th March, 8 p.m. Paper to be read on "The Construction and Use of the Hopper Dredger," by Mr. A. C. Schönberg, M.Inst.C.E.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Wednesday, 14th March, 7-30 p.m. Ordinary meeting. Discussion on Mr. J. T. Milton's Paper on "Slide Valve Gears." Paper to be read on "Stockless Anchors and Fittings," by Mr. G. W. Sivewright.

ROYAL INSTITUTION OF GREAT BRITAIN.—Thursday, 15th March, 8 p.m. Lecture on "Microscopical Work on the Least and Simplest Forms of Life," by the Rev. W. H. Dollinger. —Friday, 16th March, 9 p.m. Lecture on "Coral Reefs and Islands," by Mr. John Murray.

ARCHITECTURAL ASSOCIATION.—Friday, 16th March, 7-30 p.m. Ordinary meeting. Paper to be read by Mr. A. Oliver.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 16th March, 3 p.m. Paper to be read on "The History of the Native Army of Bombay from 1837 to 1887: its Constitution, Equipment, and Interior Economy," by Major-General W. E. Macleod.

THE SOUTH STAFFORDSHIRE INSTITUTE ON IRON AND STEEL WORKS' MANAGERS.—Saturday, 10th March, 6-30 p.m. Ordinary meeting. Paper to be read by Mr. Thomas Turner, Assoc.R.S.M., on "Notes on American Foundry Iron," by Mr. W. J. Keep, C.E., Superintendent of the Michigan Stove Company, Detroit, Michigan, U.S.A., and Mr. T. Turner.

PRICES CURRENT, 8TH MARCH.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—The copper market is gaining in strength as the arrangements of the French syndicate are being widened and strengthened. An arrangement has now been made with nearly all the English smelters, by which they are included in the operation. Prices for manufactured copper will now be steadied, as there is scarcely any chance of underselling, and the present price of "strong" is a low one relatively to the market price of raw copper. Chili bars are quoted at from £81. 15s. to £82, whilst the price of strong copper is £90. It is expected, therefore, that orders for manufactured copper, so long withheld, will now be brought out, and that the copper trade will be in a healthier condition.

TIN.—Quotations for Straits keep steady at about £166 per ton for spot parcels. Stocks are well held, and prices show no signs of giving way at present.

LEAD is again a trifle easier. Spanish is quoted £14. 15s. to £14. 17s. 6d.

SPELTER.—We have no change to report.

THE "DEFLECTOR" MINERS' SAFETY LAMP.—Mr. Andrew Howat, of Manchester, has lately designed a new miners' safety lamp which is an improvement on the Mueseler and Marsaut lamps. The leading feature of novelty is the use of a flanged ring of metal fitted tightly between the outer metal bonnet and the outer gauze cylinder, and fixed upon the rods of the lamp frame at a convenient distance above the air inlet. This flanged ring acts as a deflector, and by it the whole of the air admitted for combustion near the bottom of the bonnet is deflected downwards, passing through the gauze into the burner portion of the lamp. The light burns brilliantly, and there is no danger of the flame travelling through the gauze.

HOME INDUSTRIES.

MANCHESTER, 8TH MARCH, 1888.

THE IRON TRADE.—The iron trade in this district is passing through a period of stagnation. There are several large parcels of iron to be ordered, but buyers expect a further fall in quotations, and act accordingly. The chronic congestion in pig iron stocks prevents any advance in price. Bar iron is in the same condition as pig, and although makers profess to be very firm there is a decided weakness in quotations, common bars being purchasable at £5 per ton. Steel is a little firmer than iron, and a considerable quantity of plates and bars are being sold. Girders and constructional wrought iron work are selling very slowly. It is generally expected, however, that when prices have settled down all classes of iron will be bought much more freely than at present.

THE ENGINEERING TRADES.—There is very little change in the position of engineers in the district, but the tendency is decidedly towards improvement. A few days ago the wages question created new difficulties at Blackburn. A partial strike occurred, which has ended in an advance of wages of 2s. per week, half of the advance to take place at once, and the remaining half in June. Boiler makers continue to be well employed, and are receiving many new orders; and, generally speaking millwrights are doing well. Tool makers are also obtaining a greater number of orders. Machinists continue to be busy, and are in a condition which is highly satisfactory with regard to everything except that of prices. It is again stated that the premises lately occupied by the Junction Iron Works Company, at Miles Platting, have been purchased by Mr. Samuel Brooks, who intends to manufacture carding engines and roving frames. Loom makers are all busy, and in the bulk of cases are sold well forward; but the quotations for plain calico looms are now very low. Gas engine makers are moderately employed; but we understand that the new form of gas engine manufactured by Messrs. Andrews & Co., Limited, of Stockport, is being freely sold, having been lately much simplified by the removal of the slides.

A NEW PATENT COTTON OPENER.—Messrs. Crighton and Son, of Manchester, have just put in the market a new form of cotton opener which embodies many improvements. The grids are altered in design, so that the cotton is driven by the beater arms into recesses of such a shape that the cotton can remain motionless until the beater has passed. The bottom of the recesses are open, and the effect is that while the material is in the recess any dirt, leaf, or seed can readily fall. The defect observable in the ordinary type is that the leaf and seed in being forced through the grids carry a portion of the fibre with them, and this is entirely obviated in the new patented machine of Messrs. Crighton. The cleaning is more perfect than in the ordinary machine, while the amount of extra cotton passed through, which was formerly wasted, is from 1½ to 2 per cent.

LONDON, 8TH MARCH, 1888.

THE MONEY MARKET.—The demand for money is only moderate, but rates are harder than they have been for weeks past, for the supply is rather short. On Monday those who had borrowed from the Bank for a week for settlement purposes were not able to relieve themselves from their obligations to the Bank, as there was not enough money outside, and a considerable proportion of the loans had to be renewed. The discount rates for long bills remain easy. The stock markets are still quiet, there being exceedingly little business to transact. There are consequently but few alterations in prices, except where speculative dealings affect the market. Diamond shares are the favourite medium for speculation just at present, and there seems no limit to the extent to which the shares of the South African diamond mines can be driven up. The tone in foreign securities is firmer, and copper shares look healthier again, if there can be real health where the strength is at best artificial. The improvement is due to the conclusion of arrangements between smelters and the syndicate. The fears of the embodiment of a conversion scheme in the Budget still tends to depress the market for British funds.

COMPANIES.—The following new companies have been registered since our last report: The Union Cement Company, Limited, with a capital of £25,000; Lofts' Patent Stove Company, Limited, with a capital of £10,000; Taylor's Eagle Brewery, Limited, with a capital of £140,000; the Bournemouth Electric Light and Power Company, Limited, with a capital of £4,000; Gold King, Limited, with a capital of £350,000, to work mines in the United States; the Gas Patents Syndicate, Limited, with a capital of £25,000; the Gülcher (New) Electric Light and Power Company, Limited, with a capital of £70,000; the Comstock Mining Company, Limited (United States), with a capital of £250,000; the Ship Canal Lock Company, with a capital of £300,000; James Chambers & Co., Limited, with a capital of £20,000, to carry on the business of soap manufacturers; Flower & Son, Limited, with a capital of £350,000, to carry on business as brewers; the African Mines Development Company, Limited, with a capital of £20,000; the Union Dairy Company, Limited, with a capital of £100,000; the British Gas Meter Company, Limited, with a capital of £10,000; the South-Western of Venezuela (Barquisimeto) Railway Company, Limited, with a capital of £240,000; The Paper Fibre Company, Limited, with a capital of £60,000; Jagersfontein and South African Diamond Mining Association, Limited, with a capital of £250,000; the South Tokatea Gold Mine, Limited (New Zealand), with a capital of £95,000; the Castlecarry Fireclay Company, Limited, with a capital of £10,000; the Scandinavian Stove Company, Limited, with a capital of £5,000; the Magnetic Iron Mountains Smelting Company, Limited, with a capital of £200,000; the Crow's Nest Gold Mining Company, Limited (Nova Scotia), with a capital of £100,000; the Old Lout Mining Company, Limited (United States), with a capital of £105,000; the Ticket Punch and Register Company, Limited, with a capital of £50,000, to carry on the business of mechanical and electrical engineers; New San Acasio Mine and Freehold Land Company, Limited (Mexico), with a capital of £400,000; the Adamant Cement Company, Limited, with a capital of £50,000; and the Llwyd-Coed Slate Quarry Syndicate, Limited, with a capital of £16,000. During February 233 companies were registered, with a total capital of £17,755,235.

METALS.—The stocks of copper in England and France at the close of February are stated by Messrs. H. R. Merton & Co. at 44,943 tons, while 6600 tons are advised from Chili, and 1050 from Australia, making a total of 52,593 tons, as compared with 45,492 tons at the close of January, and 59,546 tons at the end of February last year. It is stated that the principal lead merchants of the United States have made an arrangement with the European lead producers for the "call" of their output for three years at £16 per ton. If this be correct, a rise in lead may be anticipated.

THE NAVY.—In the memorandum explanatory of the Navy Estimates, issued by the First Lord of the Admiralty, it is stated that a year ago it was anticipated that during the financial year 1887-88 twenty-five ships, with an aggregate displacement tonnage of over 90,000 tons, would be completed. This programme has been nearly realised. Six armoured ships have been completed, one completed with the exception of having her guns on board, and three will be ready in a few months. Fifteen protected and unprotected vessels will also be added before the close of the financial year. In addition, rapid progress is being made with the armoured ships "Camperdown," "Anson," and "Immortalité," and the protected cruiser "Forth." Work on the "Trafalgar" and "Nile" is well advanced.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 26th February, amounted to £1,063,955, on 15,831¾ miles; as compared with £1,106,437 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 122¾ miles, or 0·7 per cent., and a decrease in the receipts of 3·8 per cent. The Betchworth Tunnel, on the London and Brighton Railway Company's line, near Dorking, which has been closed since last July, when the roofing fell in, was re-opened for traffic last week. A new line was opened on the London and South-Western system, on Tuesday, between Brockenhurst and Christchurch, which considerably shortens the journey between London and Bournemouth. The line is between ten and eleven miles in length.

THE ITALIAN TARIFF.—The British Chargé d'Affaires at Rome informs the Foreign Office that the new Italian Customs tariff will be applied at once to all foreign imports except French goods, on which differential duties will be levied. Except in the case of goods imported direct from British ports, certificates of origin will be demanded in the case of all imports.

GLASGOW, 8TH MARCH, 1888.

STOCK EXCHANGE.—At a meeting of the members of the Stock Exchange, held last Friday, it was resolved to reduce the charges for commission on the purchase and sale of stocks. The rates upon certain classes of stocks are reduced 50 per cent. During the past week the market has fluctuated slightly, showing a hardening tendency in some securities.

COPPER SMELTING IN SPAIN.—The decree of the Spanish Government prohibiting open air smelting has caused some interest in Glasgow, owing to the large copper interests here. The prohibition, following upon the consolidation of the copper syndicate, is likely to have some effect in maintaining the advanced price.

SHIPBUILDING.—Messrs. T. B. Seath & Co., of Rutherglen, have received instructions from the North British Railway Company to build a paddle saloon steamer for their Clyde coast traffic. The new vessel is to be 200ft. long by 21ft. beam. The engines and boilers will be made by Messrs. Hutson & Corbett, Glasgow. An order has been placed by Messrs. Hermann, Stursberg, & Co., New York, with Messrs. Russell & Co., Greenock, for a steel screw steamer to carry 3500 tons of oil. The dimensions of the vessel will be: Length, 310ft.; breadth, 39ft.; depth, 25ft.

THE ADMIRALTY AND SCOTCH COAL.—H.M.S. "Devastation," now lying in the Forth at Queensferry, has been supplied with a quantity of Scotch coal. It will be remembered that representations were made some time ago as to the needlessness of bringing Welsh coal round by steamer for the use of the guardship.

ELECTRIC LIGHTING OF MUNICIPAL BUILDINGS.—At the monthly meeting of the Town Council, held on March 1st, the recommendation of the Committee on the New Municipal Buildings as to electric lighting was adopted. The Council decided to accept the offer made to them by Messrs. Muir, Mavor, & Coulson, for the supply of an electric current from their central station in Miller-street. The contractors will supply a current at a potential of 100 volts for 600 16 c.p. lamps, at a rate chargeable by meter of 5s. per 100 ampère hours. A minimum charge of £250 is to be made, a discount of 20 per cent. being allowed on charges above this. The contract is fixed for three years, with an option on the part of the Corporation to extend it should they think fit.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.—At a meeting of this society, Mr. Maclean, President, in the chair, Mr. Thomas Gray, B.Sc., exhibited and described an improved apparatus for the determination of the intensity of the horizontal component of the earth's magnetic field. A magnetometer, consisting of a small magnetic needle, about 1 cm. in length, mounted in a light aluminium frame, carrying a small mirror suspended in a vertical glass tube, fixed to a wooden base plate, is supported on a light but rigid wooden frame, which is capable of turning round a vertical axis. Two deflector magnets, mounted on suitable stands, are carried by a strip of thick glass which turns round the same vertical axis in such a way that the deflectors are always on opposite sides, and at equal distances from the magnetometer needle. The method is, in principle, the same as that of Gauss, and the apparatus is a more perfect form of that described by Mr. Gray in the "Phil. Mag." for December, 1885, the *sine* method being adopted in this case instead of the *tangent* method, as described in the paper just referred to.

(From our own Correspondents.)

LIVERPOOL, 7TH MARCH, 1888.

NEW INDUSTRY FOR BEBINGTON.—On account of the ship canal works interfering with the soap works of Messrs. Lever Bros. of Warrington, they have purchased land at Bebington adjoining the Bromborough Pool, and have now commenced the erection of very extensive works, which, when completed, will cover nearly 3 acres. The buildings will be all fire proof, and will be divided into departments, each specially constructed for the different operations, and will consist of soapery, frame room, drying room, stamping room, offices, workmen's dining room, mechanics' and joiners' shops. There will be a railway shed, and a loading pier for the steamers of the firm, which will have easy access into the Mersey from the Pool outside the Liverpool Docks and Harbour Board estate, thus avoiding all dues. The amount saved on tallow for master porterage, railway carriage, dock and town dues, will be about 8s. 7d. per ton. Electric light is to be provided, and there will be a tower 90ft. high, with a capacious tank for fire extinguishing and other purposes. The foundation stone was laid on Saturday last.

THE TIMBER TRADE.—There has been very little import of Quebec pine during the last month, while the consumption has been larger than either of the previous two years in February, and if the present consumption continues the market will soon be empty. The present stock consists of about 144,000 cub. ft. square, and 148,000 cub. ft. waney. The imports of pitch pine have been 28,000 cub. ft. hewn timber, and 2000 cub. ft. planks; the consumption has been 76,000 cub. ft. hewn, 157,000 cub. ft. sawn, and 5000 cub. ft. planks; the present stock amounting to about 360,000 cub. ft. total, 78,000 cub. ft. of which is sawn. About 1000 cub. ft. of red pine have been consumed, a similar quantity now remaining in stock. During the past month there has been a large consumption of N.B. and N.S. spruce and pine deals. 115,000 cub. ft. of oak have been imported, the consumption having been 96,000 cub. ft.; the present stock is very large, amounting to 221,000 cub. ft. Honduras mahogany is in good request, and early supplies of Tabasco should command good prices. The last cargo of Minatitlan was sold by auction on the 27th ult., at full prices.

SHEFFIELD, 7TH MARCH, 1888.

THE HEAVY TRADES.—The output of Bessemer and crucible steel is very great, and the former particularly is growing in demand. Springs, tyres, axles, and other railway material are on order both for home and Colonial railways; and one firm in the locality is busy on best sections of rails for Continental use. The engineers are busy, chiefly for foreign customers; and China is ordering heavy manufacturing materials. At the rolling mills work is plentiful, and for ship plates there is a moderate call. Crucible cast steel castings are on extensive order, and the noted firms, who have made this branch a specialty, are well off for work.

LIGHT BRANCHES.—A fairly satisfactory trade is being done in cutlery and electro-plate. Travellers on the Continent report an increasing demand for general hardware, and orders for best descriptions of cutlery are more numerous.

LEAD.—Considerable interest has been aroused by the statement that a lead "corner" is being formed. If such turns out to be the case some of the Yorkshire and Derbyshire dales, rich in stores of lead, should be benefited. For years lead has been at such a price that it has scarcely paid for the getting. But with a prospect of higher quotations, and the promise of the Midland Company to construct a railway from Dore to Chinley, the mine owners of the Peak of Derbyshire may find that their opportunity is at hand.

Digitized by Google

LEEDS, 7TH MARCH, 1888.

IRON AND STEEL.—Purchases of iron and steel have not been quite so extensive within the past few days, owing to rather firmer prices. Buyers are waiting, most of them being under the impression that quotations, in view of the keen competition, will fall again. Nevertheless, the demand for heavy material continues brisk. The makers of hydraulic machinery, and various descriptions of shipbuilding material, are very busy; and there is a good market for boilers, small engines, and some kinds of colliery plant. Railway material is also in request; and though orders for locomotives on home and foreign account are not so plentiful as they might be, still makers are sanguine that the steady development of railway enterprise must benefit them before long. It has been suggested that a railway on the Lartigue system should be made from Leeds to Roundhay Park. For station roofing, fencing, and similar work there are good orders on hand, and engineers' tools and cut nails are selling well.

TEXTILES.—Owing to the prolonged winter and the delay in the spring demand, many houses are only doing a quiet trade. Some firms are still busy with heavy woollens. The ready made clothing factories are working hard in anticipation of an extensive spring and summer demand. There has been a flutter in some quarters of Leeds about Lord Dunraven's inquiry into the sweating system in the East End. Many foreigners are employed in the ready made clothing departments of Yorkshire towns; and it is not unlikely that the sphere of the inquiry may be extended to the provinces.

NORTH STAFFORDSHIRE, 7TH MARCH, 1888.

STEEL WORKS.—The preparations of the Shelton Iron and Steel Company for the production of steel are now approaching completion, and the company hope to have their metal in the market in a short time. The progress of this new departure in local trade has been watched with much interest in the district, and its further successful development is awaited.

STAFFORDSHIRE CHAMBER OF AGRICULTURE.—At a well attended meeting of this chamber, held at Stafford on Saturday last, Mr. T. Carrington Smith, the chairman, introduced a discussion on the recommendations contained in the report of the Department Commission for the promotion of agricultural education by the establishment of farming or dairy schools, and he alluded to the generally prevalent desire throughout the country for some system of technical education. Mr. Smith briefly reviewed the principal suggestions of the committee in connection with agriculture, these being: (1) That increased facilities should be offered for the study of its principles in rural elementary schools, and that gardens, allotments, and farms should be encouraged in connection therewith; (2) that intermediate schools should be founded for this purpose; and (3) that a central school of agriculture should be established for Great Britain, probably at Rugby. The Railway Rates Bill now before Parliament was also discussed, and the following resolution unanimously passed: "That this chamber urges Her Majesty's Government to amend their Bill dealing with railway rates, so that such Bill should prohibit railway companies from charging preferential rates for foreign manufactured goods or imported produce."

BIRMINGHAM, 7TH MARCH, 1888.

THE HARDWARE TRADES.—Business in these industries is by no means so brisk as it was at the beginning of the quarter. This state of things is directly traceable to the speculative advance in the price of metals. By the action of the syndicate metals have been forced up to a position quite out of all relation to the demand for finished goods. Some manufacturers who were well stocked before the rise can do business at present prices with a profit, and they are underselling those who were not so fortunate or so shrewd. The orders for spring goods that are now coming in are certainly disappointing, this being, however, due to the bad weather, which is the chief factor in causing the briskness which exists among manufacturers of heating appliances, stoves, fenders, and similar goods. In brass tubes and sheets there is little doing, but for steel tubes and steel and iron locomotive and general railway appliances there is a fair demand for the Indian, Colonial, and other foreign markets.

THE WATER COMMUNICATION SCHEMES.—The committee appointed by the Birmingham Corporation to examine the various proposed schemes for establishing improved water routes between the Midlands and the sea coast have, it is understood, decided to report in favour either of the route *viâ* the Trent Valley to Hull or of the London scheme. Communication with Liverpool they consider equally important, but there is at present no definite proposal for a waterway in this direction. They are in favour of the work being undertaken by a public trust, and recommend that the Government should be asked to insert clauses in the Railway and Canal Traffic Bill empowering local bodies to deal with canal trusts.

SOUTH WALES, 7TH MARCH, 1888.

BARRY AND CADOXTON GAS WORKS—The directors of this company report that they hope to have the works ready to supply the district by the coming autumn. £2,232 had been expended up to 31st December, leaving a balance on the called up capital of £3,898.

THE WELL'S LIGHT.—Messrs. Cross Brothers, of Cardiff, have been exhibiting at the Hayes this economical form of "Lucigen." It is claimed that one lamp can produce a light of 2000 to 3000 candle power, at a cost of about 3d. per hour, and, no doubt, it will be found invaluable by contractors and for night work in large open spaces.

IRON PYRITES.—La Société Commerciale d'Affrétements and de Commission of Swansea and London are introducing an exceedingly pure ore almost wholly composed of iron and sulphur, which they are importing from Spain, and from which a very pure acid is obtained. Some lots recently imported are said to have given satisfaction, but the price, about £1 per ton f.o.b., militates against its extensive use.

BARROW-IN-FURNESS, 7TH MARCH, 1888.

GENERAL TRADE IMPROVEMENT.—The general increased confidence which has followed the resuscitation of the shipbuilding trade at Barrow, and the acquirement of the large yard of the Barrow Shipbuilding Company by the Naval Construction and Armaments Company, Limited, is showing itself in a variety of ways. Shop property which has been tenantless for years, is being taken up by tradesmen anxious to avail themselves of an improved trade which has yet to come, and the doleful hopes which were at one time entertained in reference to the commercial state of the town have given way to brighter anticipations for the future.

IRON AND STEEL.—There is no change to note in the iron and steel trades. Orders are freely offered for pig iron, but prices are at a very low point, and makers still decline to recognise the prices at which hematite warrants are changing hands, but quote 43s. 6d. to 44s. per ton net f.o.b. for mixed parcels of Bessemer iron, and at these rates some of the best brands have been sold. Stocks in the hands of merchants and speculators are large, and there is reason to believe that the production is too large. Steel rails are brisk at £3. 18s. 6d. for heavy sections. There is less inquiry for plates and angles, but makers are fully sold. Blooms, billets, hoops, and bars are brisk; but other classes of steel are slow of sale. There is a better tone in the shipbuilding, engineering, and ironfounding trades. Iron ore is quiet at late rates. Shipping in the district is fairly well employed.

MIDDLESBROUGH, 7TH MARCH, 1888.

PIG IRON.—The iron masters' returns for February have been a surprise. It was known that Connal's stores had been diminishing for some time, but few suspected the amount of decrease over the whole of the stocks. The 12,179 tons to which the decrease amounts should have its effect upon prices. The market, however, is more than ever in the hands of speculators. Makers are not doing much in the meantime, as they do not care to accept current prices, which are nominally 31s. 6d. for early, and 31s. 9d. for April-June delivery for No. 3 G.M.B. Warrants are 31s. 1½d. per ton cash for Connal's No. 3 G.M.B., and 42s. nominally for Connal's hematite. Makers' hematite being quoted at from 32s. to 34s.

SHIPMENTS OF PIG IRON.—These still continue to be favourable. Notwithstanding the boisterous weather the shipments for February exceed those of January by 5490 tons, and those of February last year by 14,170 tons.

FINISHED IRON AND STEEL.—The great activity in the finished iron trade has caused a scarcity of forge iron, which consequently has advanced in price so much that more has been given for forge than for No. 3—31s. 9d. and even 32s. having been paid under the pressure. In finished steel the pressure is chiefly on the plate departments. The steel rail trade is not so active, and very low prices are mentioned as having been accepted. There is still a very heavy turn-out of steel sleepers, and the docks are crowded with them, being shipped off to India and elsewhere.

SUNDERLAND, 7TH MARCH, 1888.

IRON WORKS.—There is now an activity in the local rolling mills and forges which has been unknown for years. Messrs. S. Tysack & Co., of the Fulwell Iron Works, have all their puddling furnaces in operation. The forges of Mr. Thomas Ray, Messrs. J. L. Thompson & Sons, and Messrs. Calvert & Co., are especially well supplied with work. Messrs. Lumsden & Co., Limited, of the Strand Iron Works, have also been successful in securing a number of orders for anchors and chain cables from local shipbuilders.

COAL SHIPMENTS.—The coal trade returns for last week are more favourable than for the previous one, 77,500 tons being shipped, 59,200 tons coastwise, and 18,300 tons to foreign ports. In the corresponding week of last year the total shipments were 69,917 tons; 950 tons of patent fuel, and 580 tons of coke were also shipped during the last week.

SUNDERLAND SHIP OWNERS' SOCIETY.—At the last meeting of the local Ship Owners' Society, it was reported that a communication had been received from Mr. B. Waymouth, secretary to Lloyd's Register, stating that the representation of out-ports was amended as recently as 1883, and that the committee saw no reason for increasing the number of representatives for Sunderland and other out-ports. After some discussion, in which regret was expressed that the Liverpool Underwriters' Registry no longer existed, the formation of a new opposition classification society was advocated, and it was ultimately agreed to communicate with the Clyde and Newcastle Associations to endeavour to arrange for further joint agitation.

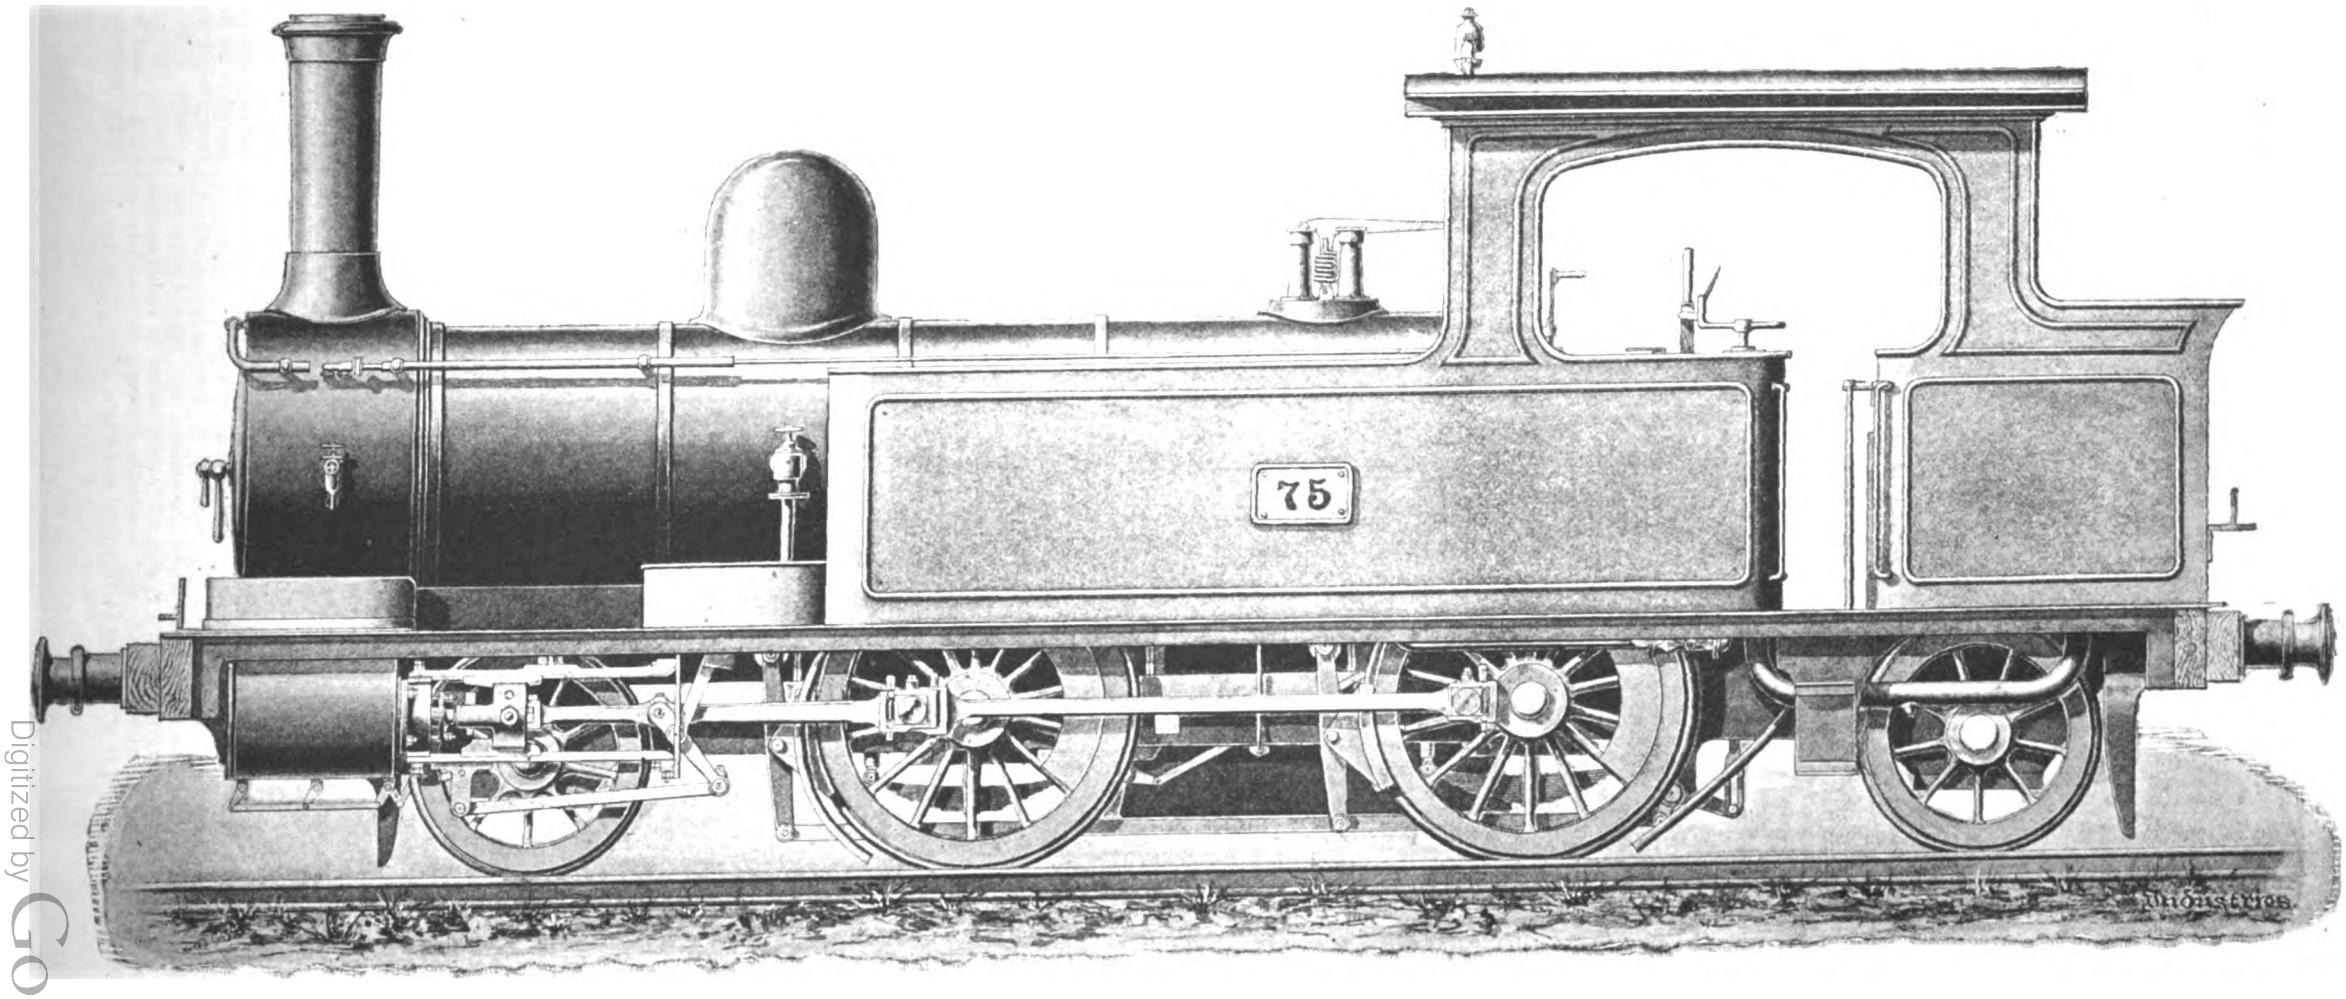
NEWCASTLE, 7TH MARCH, 1888.

SHIPBUILDING.—Judging by the appearance of the yards the shipbuilding industry in this district is now in almost as satisfactory a condition as it was at the height of the busy period which terminated in 1884. The most notable event which has recently occured in connection with the industry, is the re-opening of Messrs. Palmer's Howdon yard, which took place towards the close of last week. The keel for a vessel of the largest class is now being laid in one of the berths, and arrangements are in progress for the laying down of several other keels immediately. It is estimated that by midsummer at least 1000 hands will be employed at this establishment, which has been unproductive for the past four years; and there is reason to believe that its re-opening has not, on the present occasion, been resorted to as a mere temporary expedient to work off pressing orders, but that the firm intend to keep it permanently going in the future. At the Jarrow yard belonging to the firm there are seven vessels, representing over 20,000 tons carrying capacity, on the stocks, and other large vessels are to be laid down as soon as berths are ready for them. Messrs. Hawthorn & Leslie have put down keels for four vessels lately, and two others are being plated and framed. Messrs. Armstrong, Mitchell, & Co. are commencing the construction of three large vessels at their Low Walker yard, while two others are in frame, and a sixth (intended for the petroleum trade) is being prepared for launching. Messrs. W. Richardson & Co. have just put down two keels, which, with the vessels in progress, make five berths occupied. The firm have ordered from a Sunderland boat builder thirteen boats (eight of them lifeboats) for a large mail steamer they are about to launch, and which, it is understood, has been sold to a Spanish company. Messrs. Swan & Hunter have on the stocks four large vessels, one of which will shortly be launched; and Messrs. Schlesinger & Davis, who at present have only two berths occupied, will shortly have double that number in use, as they have just secured orders for two vessels. The Tyne Shipbuilding Company are busily pushing on the work of three large vessels ordered by local owners, and they have other important orders on their books. Messrs. Readhead and Messrs. Dobson have all their berths occupied, and Messrs. R. Stephenson & Co. have three keels laid, besides a vessel in course of plating.

ENGINEERING.—Every large marine engineering establishment on the river is now quite full of work, but, as in other departments of the engineering industry, trade is not so brisk, and nothing like a scarcity of hands has yet been experienced. Messrs. Hawthorn & Leslie are now engining the second of the Chinese passenger steamers lately launched from their Hebburn yard. In the locomotive branch business is not particularly good, and some establishments, which formerly made this class of work their exclusive specialty, are now largely engaged in marine work. The ordnance works at Elswick are scarcely so busy as they were a few months ago, and a gradual reduction of hands has been taking place for some time past. The brassfounding department of Messrs. Watson & Son's establishment, High Bridge, Newcastle, is especially brisk at present, and they have a great many orders for their special pumps for steamship use. This firm are about to introduce a new "mechanical lubricator," the invention of Mr. J. R. Fothergill, of Hartlepool. The makers have formed very high expectations regarding the success of this invention, and their confidence appears to be well grounded, seeing that in a recent trial at sea, extending over a period of two months, it proved admirably adapted to the purpose intended. It may be stated that it gives a constant sight feed, and appears to be quite free from the objections known to exist in condensing lubricators. Messrs. Noble & Lund, machine tool makers, Forth Banks, have been very busy for some time past, and have still several orders to execute for machine tools of various descriptions.

BELFAST, 7TH MARCH, 1888.

SHIPBUILDING.—Great activity is still the rule in the various yards, and the stocks are rapidly filled up with vessels of large tonnage. During the past fortnight Messrs. McIlwaine & Lewis launched a large steel screw steamer named "Titanic," for Messrs. H. & J. Scott, of Belfast; and Messrs. Workman, Clark, & Co., Limited, launched the first of the two caissons for H.M. Dockyard at Haulbowline. Messrs. Harland & Wolff are reported to have received an order for a large screw steamer, one of four just placed with various builders by a Liverpool firm for their Atlantic, Mediterranean, and Danube trades. This firm has also completed and handed over the s.s. "Oceana," the latest addition to the Pacific and Oriental Company. This fine vessel was entirely built, engined, and equipped at Belfast. Repairs are more numerous than earlier in the winter, and several cross Channel steamers are at present undergoing their annual overhaul.



MINING.—Two important discoveries have been made in the North and South of Ireland. Syenite of the finest quality and of a rich emerald green colour has been found by Mr. Joseph Weir, Rosstrevor, in one of the hills of the Mourne range, which was already known to contain red and grey granite. Gold has also been found near Dunmanus Bay, County Cork; several samples of the quartz have been assayed, and have been found rich in gold. The lode is said to be about 1¼ mile long by 6ft. wide.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Offices for Publication:
22, Wellington-street, Strand, London, W.C.
70, Market-street, Manchester.
62, St. Vincent-street, Glasgow.

FRIDAY, 9TH MARCH, 1888.

THE PARIS EXHIBITION.

IT is gratifying to learn, from the proceedings which took place at the Mansion House on the 29th ult., that the unfriendly attitude assumed by our Government towards the great French Exhibition of 1889 will not have the baneful influence on British industry which at one time seemed inevitable. The question, hitherto obscured and distorted by political animosities, begins to offer itself in another and a truer aspect. Viewing it in this new light, we are disposed to regard with wonder the spectacle of our rulers, and others in exalted stations, holding aloof from an undertaking of this character on the ground of a coincidence of dates, that seemed to impart to it political significance. The anarchist party in France has striven to connect this Exhibition with the centenary commemoration of the Great Revolution. But for the great majority of persons it is but a repetition of the scientific, industrial, and artistic show held in Paris in 1878. Its character is mainly industrial. It is designed to exhibit the progress made within the last eleven years, and to afford an opportunity to manufacturers to ascertain their relative position in the industrial world, and to buyers to inform themselves concerning the actual state of industry and trade. It would ill become us, who pride ourselves on our practical good sense, to refuse to take part in an exhibition of this nature on mere sentimental grounds. Happily this folly is not likely to be committed. The spirit of independence which animates our manufacturers has been aroused, and a vigorous effort is being made to repair the mischief done. After all the attitude of the Government is not wholly to be regretted. Individual enterprise has been stimulated to action, and British manufacturers, left to their own resources, have found the occasion one in which they may dispose of their affairs in the way most conducive to their interests. The co-operation of the Government in past times has not been productive of unmixed good. Unpleasant recollections gather round what is known as the "South Kensington ring." It is not our business to seek out the grounds of this discontent; it is enough that it exists. Clearly, with this distrust on the one side, and irritation on the other, there could be no sympathy between the representatives of the Government and those in whose interests they were deputed to act. As matters now promise to shape themselves, there is hope of obtaining efficient representation through an organisation composed of chosen members, and subject to control. Thanks largely to the initiative of M. Berger, and the hearty co-operation of the Lord Mayor, a movement has been set on foot to promote this object. Already their efforts in this direction have borne fruit in the appointment of a Provisional Committee and the formation of the nucleus of a fund for carrying the project of a complete Executive Committee into effect. This committee will allot space to exhibitors, make and collect such charges as may be necessary to cover the costs of the British Section, and generally look after the interests of the parties concerned. The influential character of the Provisional Committee is a guarantee of success; it now remains for intending exhibitors to second the efforts made on their behalf by responding promptly to the invitation.

No argument is needed to force home the obvious truth that British industry must be amply represented at Paris in 1889. The occasion will be one of perhaps unparalleled importance. Place and time are favourable to the event. Paris is a peculiarly suitable spot for an exhibition of this sort, being easily accessible from all parts of the Continent, and a centre to which men from all parts of the world seem naturally to gravitate. The period, if only peace be preserved in Europe, is likely to be one of brisk, if not thriving, trade. In such circumstances, absence, or what would perhaps be worse than absence, an imperfect and mean exhibit on our part, would amount to a confession of weakness very damaging to our reputation. It would be to relinquish to our rivals all the advantages of the situation. The time has gone by when we could treat our customers in this masterful fashion. We have already lost heavily from our unwillingness to admit the possibility of a rival becoming formidable. Year by year competition grows keener, and in 1889 the Champ de Mars will become an arena in which the struggle for supremacy will be very fiercely engaged in. What the United States Government thinks of the opportunity is sufficiently shown by its grant of £40,000 to insure a fitting representation of its manufactures. Besides the United States, and the Central and South American Republics, Switzerland, Greece, Servia, and Japan will be officially represented. The countries which will be unofficially but probably largely represented are Great Britain, Belgium, Holland, Italy, Spain, Portugal, and Turkey. Executive committees are being organised at Vienna, Buda-Pesth, St. Petersburg, and Warsaw. England and Germany are the only countries where no National Committee has been formed; but the latter country now seems disposed to abandon the attitude of reserve hitherto maintained. Of our colonies, New South Wales, South Australia, Victoria, and New Zealand will be strongly represented. The Canadian Government is disposed to aid any of its subjects who wish to exhibit, and arrangements are being made to give prominence to Indian produce. To mention these facts is to show the impossibility of abstention on our part.

An important question for intending exhibitors is that of cost. In this matter the French Government promises to deal liberally with its guests. Space in the Exhibition will be allotted free, but a charge will be made to cover the cost of flooring, partitions, decoration, and general supervision. These items will together amount to a sum varying from £1 to £1. 10s. per square metre of flooring. The total space reserved for the British Section is about 5500 square metres. It will be well to warn intending exhibitors that gangway space will be deducted; that is to say, of 100 square metres applied for, only about 50 or 60 square metres may be available for stands. Here the proposed Executive Committee will confer advantage by economising expenses, and acting as intermediary between the French authorities and the exhibitor. Stands and glass cases and covers for the exposition of goods will be received and returned duty free, as in 1878. The cost of installation in the case of machinery in motion will depend on the magnitude of the works required for foundations. The aggregate of the costs in the agricultural section will scarcely exceed 15s. per square metre. An important consideration is the cost of transport. This has been reduced to a minimum by the generous con-

Digitized by Google

cession of 50 per cent. on the ordinary rates charged by the French railway companies for all goods conveyed to and from the Exhibition, except works of art and specially valuable articles. A uniform charge of 10 francs a ton will be made for the conveyance of goods from the railway station to the Exhibition building. The French authorities are careful to point out that the whole of the material required for the fitting up and decorating of the British Section may be worked up in England and imported duty free at these reduced rates. The representatives of the London, Chatham, & Dover, and the South-Eastern lines present at the Mansion House on the 29th, expressed their willingness to afford exhibitors every facility for the transport of goods. The Lord Mayor says he is acting with the full approval and concurrence of the Government. There should, therefore, be no insuperable difficulty in the way of carrying out the project which he has undertaken to promote. The way has been cleared, and it now rests with the manufacturers themselves to evince their interest in the matter by contributing their share in the furtherance of the scheme.

ELECTRIC LIGHT LEGISLATION.

Lord Thurlow's Electric Light Act Amendment Bill was read a second time in the House of Lords on Monday last. The arguments brought forward in support of the Bill, and the discussion which followed, did not materially differ from what took place in the House of Lords about a year ago. At that time everybody was agreed that the Electric Lighting Act of 1882 should be amended, and yet owing to political complications nothing could be done in the interval. We referred to this question in our issue of the 11th March, 1887, and the arguments we then used in support of the Bill are still valid, but since that time they have acquired additional force. A year ago the distribution of electricity by alternating currents and transformers was just beginning to make headway in the United States. At the present moment this system forms one of the most important industries in that country; and to judge by the rate at which it has come into favour, a further and much larger development of it will doubtless take place within the present year. Well might English electricians cast envious glances upon their successful American rivals, who, instead of having to wait for the removal of restrictive legislation, can devote all their energies to actual practical work, and do a large business, which benefits not only themselves but also their customers. Lord Thurlow, in introducing the Bill, pointed out that since the passing of the Electric Lighting Act of 1882, fifty-nine provisional orders and five licenses had been granted to companies, and fifteen provisional orders and two licenses to local authorities. We need hardly remind our readers that in nearly all these cases these powers were obtained not with a view to immediately begin work, but simply for the purpose to hold the field against possible rivals, who might otherwise have later on acquired the right of supplying electricity to the districts concerned. The companies and local authorities who applied for licenses or provisional orders had at the time of their application no very distinct idea how to set about for doing the work; but they thought it prudent to take such a legal position as would enable them at any future time, when they could elaborate a definite scheme, to carry this into execution. Unfortunately, this time had not arrived when the provisional orders lapsed, and most of these enterprises may now be regarded as finally shelved. The position of the electric lighting industry in this country may therefore be truly described as anomalous. Notwithstanding the fact that England was first in developing the dynamo machine, the storage battery, the glow lamp, the transformer, and various systems of distribution on a scientific basis, we have hardly any large central stations for the public supply of electricity, whereas in the United States there are, according to Lord Thurlow, 120 electric light companies, paying dividends of from 6 to 14 per cent., and in Germany there are 604 companies supplying electricity. Even in a country like Italy, which we are apt to regard as being backward in modern improvements, the electric light is making rapid headway in all the large towns. Viewed in the light of these facts, insufficiency of apparatus cannot be pleaded as the reason for the absence of progress in this country, and we must look for the causes to legislative restrictions, and the timidity of capitalists. We are assured by Lord Thurlow that about one hundred millions worth of capital could find useful employment if the legislative restrictions to electric lighting were removed. This figure, though very large, does not seem excessive if we consider that the estimated capital of American electric lighting undertakings has already reached about forty millions.

Now what are the legislative restrictions which prevent the useful employment of this capital and a proportionate amount of labour? First and foremost it is the clause providing for the compulsory purchase of the central station by the local authorities at the expiration of twenty-one years. Lord Thurlow in his Bill last year suggested that if compulsory purchase without making any allowance for goodwill was to remain a provision of the Bill, this purchase should not take place before the expiration of fifty years, or at least forty-two years; but on the whole he should prefer to shorten the preferential term, and provide for a system of purchase under which the station would be taken over as a going concern, with a fair allowance for the goodwill of the business. In the present Bill the term of compulsory purchase is settled at forty-two years, and we think no reasonable objection can be urged against the clause. To object to compulsory purchase after forty-two years on the ground that the electric light contractors would during that period not have had sufficient opportunity for recouping themselves for their outlay, would be tantamount to a confession that the supply of electricity must be a losing business, and such a proposition must of necessity prevent capitalists from investing money in electric light undertakings. If American companies find it possible to earn a dividend of from 6 to 14 per cent. within a few years of establishing their stations, there is no reason why English companies should not do the same. That the price of gas is less in England than in America can hardly influence the dividends of electric light contractors. We know perfectly well that at present we cannot supply the electric light as cheaply as gas light, but then the electric light is an article of luxury for which consumers will gladly pay two or three times what they now pay for gas. On the other hand, it is probable that, with improvements in the manufacture of incandescent lamps, the cost of lighting will yet be considerably reduced. We have lately heard of a new glow lamp brought out in Berlin, which requires only 2·25 watts per candle power. Compared with the usual incandescent lamp, this is a reduction of about 40 per cent. in the energy required to produce a given amount of light. Dynamos, storage batteries, and transformers are all being continuously improved, so that it is not unreasonable to expect that within the next few years the cost of supplying the electric light will be considerably less than what it is now. Hence, if it be possible for a central station at present to earn a dividend, when these improvements come into use the profits must naturally increase, so that a station started now may, with good management, count upon earning a very substantial dividend for the next forty-two years, after which the proprietors may well afford to sell the plant at its ordinary market value, without any allowance for goodwill. In order to work at a profit it is, however, absolutely necessary that contractors should have a limited monopoly. The supply of electricity, like that of gas and water, is in itself of such a nature that it cannot be carried on profitably except on a large scale, and to do this it is evidently important to prevent indiscriminate competition. The hardships sometimes inflicted by water companies on consumers are frequently cited as a warning why we should not allow electric light companies to obtain any monopoly; but it must not be forgotten that the two cases are totally different. Water is an absolute necessity of life. If a water company refuses to supply certain persons in a district, except at exorbitant charges, they not only prejudice the health of the persons so treated, but that of the whole district. On the other hand, if an electric lighting company were to refuse to supply certain persons in a district, these could always fall back upon gas or some other means of illumination, without suffering in health to anything like the extent which would result from their failing to obtain water, whilst the sanitary condition of the other consumers in the district would of course not be affected in the slightest degree. The objection to a monopoly is therefore not based on sanitary grounds, but is simply a commercial question. This objection may therefore be met by stipulating a fixed maximum charge for current, or by a sliding scale; but even if the charge for current were left an open question, to be settled by an agreement between the electric light company and their customers, no great difficulty could arise. Electric light companies have to meet the competition of other illuminants, and of electricity itself. At present large establishments in London are lighted electrically, the current being supplied by machinery on the premises; and it will obviously be to the advantage of the central station to induce these large establishments to become customers. It is therefore necessary that the company's charges to these large customers should not exceed the cost of producing electricity on their own premises, and if a clause were inserted into the Bill rendering any preferential treatment of large customers illegal, small customers would secure a supply on equally favourable terms.

Whilst we thus see no reason to object to giving electric light companies a monopoly for the supply of electricity, we think a clause should be added to Lord Thurlow's Bill prohibiting the use of overhead electric light wires. At present the only large central station in London—that of the Grosvenor Gallery—distributes electricity by wires stretched over the house tops and crossing the streets in all possible directions. These wires are of necessity a source of danger, not only because they are themselves liable to break and fall into the street, but also on account of the telephone and telegraph wires with which they might become entangled. Only a few weeks ago a case happened in New York, when a telephone wire snapped and fell across an electric light wire. A horse was entangled by the telephone wire and killed by the shock, whilst the driver, who went to disentangle his horse, was fortunately pulled back by a bystander, and thus escaped the same fate. Accidents of this nature are almost sure to happen if we allow high tension overhead wires to multiply indefinitely, and we hope that a clause will be inserted before the Bill becomes law under which no electric light wire of any description whatever will be allowed to be placed overhead.

PROSPECTS OF BRITISH AND GERMAN TRADE WITH ITALY.

The failure of the negotiations for the renewal of the treaty of commerce between Italy and France has directed attention to the commercial relations existing between those two countries. Interest in the question, already strong from its important bearing on the trade of Europe, has been intensified by the attitude of resistance and retaliation assumed by the French. A war of tariffs is threatened, an event that must necessarily modify in no inconsiderable degree some of the conditions under which commercial intercourse is now carried on. Italy and France, naturally bound together by the ties of race, have hitherto been closely allied in trade. Their mutual dependance, preponderating, indeed, largely on the side of the former, is strikingly apparent in the statistics of trade for the year 1886, the latest complete issue. From these we learn that the Italians sent one-half of their exports of all sorts to France, while one-third of all their imports was made up of the commodities received from the latter country. The total value of this trade amounted to £33,120,000, of which sum the exports make up £19,280,000 and the imports £13,840,000. The Italian goods purchased by French consumers consist principally of raw silk, wine, oil, cattle, and food stuffs. The French goods sold to Italian customers are chiefly the products of manufacturing industries. Of late years a certain degree of estrangement has arisen between the two peoples. Political jealousies have contributed something towards this antipathetic feeling, and something more has resulted from the agitation got up in France against the employment of Italian workmen. A consequence has been a gradually increasing loss of trade to France. The latest and not the least potent event tending to engender unfriendly sentiments, is the refusal of the Italian Government to continue to their Gallic neighbours the favour accorded them by the treaty which expired with the year 1887. This refusal has given rise to some bitterness of feeling among the French, who show their resentment by threatening to impose heavy additional duties on all goods of Italian origin. Already steps have been taken to carry this threat into effect, and a war of tariffs, which thus seems probable, must very seriously derange the commercial relations now existing between the two countries, and occasion a diversion of trade in several directions. Here arises the interest felt strongly by the Germans, and in a scarcely less degree by ourselves. The French hope to obtain a sufficient supply of the commodities hitherto derived from Italy, from Spain, Hungary, Algeria, and Tunis. But it will not be so easy to find equivalent outlets for their own goods. In this respect the Italians have the advantage. They can easily enough supply all their wants from Germany and England, and extend their export trade at the same time to Switzerland, Germany, and Belgium. Obviously, then, the changes which are taking place will be favourable to German and to British trade.

The course of political events in recent times having brought about community of interests between Italy and Germany, friendly relations have been established, resulting in close intercourse, and a transference to the latter country of a portion of the trade formerly possessed by France. These changes in the current of trade were rendered possible by the creation of better means of communication between Germany and Italy. The opening of the St. Gothard Railway in 1881 supplied what was wanting for extensive commercial intercourse, and marks the beginning of that remarkable growth of trade which has profoundly disturbed the industrial situation in France, and awakened apprehensions for British commerce with the Italian peninsula. The statistics of German

Digitized by Google

trade with Italy afford instructive reading, and it would be hard to find a parallel case of rapid growth. In the five years ending with 1886, the declared value of the German exports rose from £2,640,000 to £5,160,000—that is, it was practically doubled in half a decade. The value of the French exports shrank in the same time from £14,400,000 to £13,840,000. The increase is general; but it is chiefly observable in the commodities which form the bulk of British trade. The progress recorded in some of these is startling. Thus we find such rates of increase as the following: Coal and iron, from £440,000 to £1,280,000; woollen goods, from £360,000 to £520,000; cotton goods, from £240,000 to £320,000; colonial wares, from £320,000 to £400,000; chemical products, from £80,000 to £240,000; leather and leathern goods, from £160,000 to £240,000; glass ware, from £80,000 to £240,000; and silk goods, from £100,000 to £200,000. We have in these figures unquestionable evidence of vigorous life, and an indication of what that life may develop into in the future. If changes of this magnitude could take place under the conditions which have prevailed in the past, we may reasonably anticipate further progress when a war of tariffs between France and Italy shall have more profoundly disturbed the relations hitherto existing.

These events and tendencies claim the earnest attention of British traders. New influences are at work and changes are in progress which will affect for good or for evil—according as we bear ourselves in the matter—our position in the industrial world. If we are content to remain supine in the midst of these changes—to let events take their course without an effort to direct them, then all the advantages of the situation will be acquired by our more enterprising rivals, the Germans. But if by prompt and decisive action judiciously directed, we bring our superior influences to bear, we may turn to our own profit the opportunity afforded by these altered circumstances. We showed on a former occasion how the new traffic will tend to expand our trade with Italy in coal and pig iron to the detriment of Germany. This advantage is ours without seeking it. But to make advantages in other directions against German competition, to turn to account the present and prospective relations of France to Italy, there is need to bestir ourselves. Our trade has hitherto not shown the same vitality that distinguishes that of our rival. The total declared value of our exports to Italy amounted in 1882 to £6,480,000. In the following year this value increased to £7,122,000, from which point it gradually declined to £6,092,000 in 1886. It is true that last year it expanded to £7,794,000, an increase of £1,702,000 in one year. But we must not delude ourselves into the belief that this represents a genuine growth of trade. In part it is doubtless real. Thus we have an increase of £84,666 in coal and £136,869 in pig iron, which may be considered permanent gains. But in the main the augmentation is to be attributed to speculative dealings entered into in anticipation of the new tariff. The direction in which we may hope to gain by the conjuncture of events under consideration is chiefly that of textile goods. The products of French mills exported in 1887 to Italy amounted in value, for woollen cloth and stuffs, to £688,000, and for the heavier classes of cotton goods to £144,000. Raw wool to the value of upwards of £235,000 was also exported in the same year. Whatever shrinkage occurs in this trade must be made up by additional purchases from German and British manufactures. Add a growing consumption, and we have a fair prospect of expanding trade. But whether—and this is the point to which we wish particularly to direct attention—the advantage is to accrue mainly to German industries, or is to be largely shared by our own, is a matter that depends wholly upon ourselves. The times call for energetic action and a display of tact on our part. For this reason it is to be regretted that events have occurred, and are still in progress, of a character calculated to prejudice our interests with our Italian customers. We allude to the action which some ship owners have taken in the matter of freights to Genoa. Insufficient accommodation in that port has occasioned delays in unloading that have provoked British ship owners to retaliate with greatly increased freights. This obviously is playing into the hands of our rivals. The Chambers of Shipping and of Commerce may find a profitable occupation in seeking a less objectionable means of facilitating the discharge of cargo in Italian ports.

THE RAILWAY COMPANIES AND THE CARRIAGE OF FISH.

Under the auspices of the National Sea Fisheries Protection Association, and of Sir E. Birkbeck, its chairman, a short Bill has been introduced into Parliament to secure one uniform scale of through railway rates and charges—which may be unhampered by terminals—for the carriage of the common kinds of fish by the various railway companies of the United Kingdom. The provisions of the Bill are directed to relieving the congested state of our central wholesale markets, by obtaining reasonably cheap and rapid transport for the common kinds of sea fish, in quantities of 1cwt. and upwards, from the coast to the various inland centres of population, and thereby securing a plentiful distribution amongst our inland towns and villages, and other impoverished centres; but they are not intended to interfere with the rates now levied for prime fish, nor with those for quantities of less than 1cwt. of common fish. At the present time the rates charged under the authority of various Acts of Parliament for the conveyance of the common kinds of fish vary under different conditions and circumstances, and are often so oppressive as to retard the development of our sea fishing industry, and to restrict the distribution and consumption of this nutritious class of food. If the measure we now refer to becomes law, it will be known as the Railway (Carriage of Common Kinds of Fish) Rates and Charges Act, 1888, and will come into operation on the 1st of January, 1889. It will govern the charges for conveyance of forty-one different kinds of fish, the trade in some fourteen of which is already a large one, and may be expected to receive a considerable impetus. The revision of the existing rates proposed by the Bill is certainly of a drastic character, amounting in some instances to a reduction of over 100 per cent.; but having regard to the general circumstances of this industry, to some of which we propose to allude, and to the increase which may be anticipated to result in the volume of traffic, we are of opinion that, while conferring an inestimable benefit on the poorer classes, it would not detrimentally affect the revenues of the companies concerned. In this connection, however, some means should be contrived to insure the benefit of the proposed revision in the rates reaching the consumers, and not finding its way simply into the pockets of the retailer. This point we commend to the attention of the Conference of representatives of the sea fishing industry to be held in London during the present month.

At some of the large works and institutions of our industrial centres, quantities of the common kinds of fish are regularly purchased direct from the sea ports, and disposed of amongst employés and dependants at a price sufficient to cover the prime cost, carriage, and incidental expenses, which should average all round something under 3d. per pound. It may, perhaps, be necessary to guard here against any possible misconception of the expression "common kinds of fish." It embraces those genera of a popular character, such as cod, herrings, mackerel, shrimps, &c., as opposed to what are recognised as "prime fish," such as salmon and soles, and does not in any way touch the question of quality. The Bill also provides for the return of empty packages used in the conveyance of common kinds of fish at a charge which shall in no case exceed half the prescribed rate for the same package if it were full, and the charge is to be calculated on its actual weight as delivered to the railway company.

This is not an unfitting opportunity to direct public attention to the lack of practical results from the "Fisheries" Exhibition, which was held in London several years ago, and to the vast importance of promoting a better acquaintance with the existing conditions of our British fishing industry. In 1886, Sir E. Birkbeck obtained the assent of Mr. Mundella, as representing the Government, to his motion for the establishment of a central department, to be charged with the care and control of all the fisheries; but, owing to the exigencies of Parliamentary business, the matter has since been shelved. While the German Government carry on considerable and detailed investigations in connection with their fisheries, while statistical returns are annually published by the Norwegian Government, while the United States and Canada collect every possible information as to the productiveness and value of their fisheries, and while the Scotch Fishery Board is doing a work of great utility, England alone, though so largely dependent upon this industry as a source of food supply, and as a field of occupation, not only is without a special State Department in this connection, but actually publishes no reliable information indicative of the true condition of our fisheries, and showing whether their productiveness is increasing or decreasing. In consequence of the division of authority in fishing matters amongst different departments, the spasmodic investigations and reports of Royal Commissions have been practically fruitless. Salmon and fresh water fish that do not migrate to the sea come under the supervision of the Home Office; oysters and bait fisheries are looked after by the Board of Trade; other sea fisheries, if in English territorial waters, also come under the control of the Board of Trade, but if outside that limit, under the Foreign Office and the Admiralty; while fish landed in English ports fall under the purview of the Customs. Under such conditions it is not a matter for surprise that information obtainable with regard to our fisheries is meagre and unreliable. And yet there would seem great advantages to be derived from a regular publication of statistics of the take of fish, the time of the appearance of fish, the different conditions of temperature, wind, tide, and weather under which fish is taken, the abnormal or normal appearance of fish, and such like information. That the industry in question is of no mean importance may be gathered from the fact that the value of fish which is annually cured in Great Britain reaches a sum of £5,000,000 sterling; and there can be no doubt that a considerable development would follow from the adoption of regulations drawn up as a result of careful investigations by a central authority. Considerations of space will only permit us to give two instances to demonstrate the value of careful inquiry in this connection. Taking the herring fisheries of Scotland, about half a century ago the estuary of the Moray Firth was most sought after, and shoals of fine plump herrings, with their usual accompaniment of whales, porpoises, and dogfish, found their way up as far as Cromarty. There were large curing establishments on both sides the Firth, and for some years the fishery was abundant, when, in an unaccountable manner, the herrings suddenly disappeared, and were found only about the entrance of the Firth and on the Caithness side. It was not until 1877 that a successful beginning was made at the Shetland fisheries, and in the following year 120 boats were engaged on that ground. In 1885 there were as many as 830 boats, and the quantity of herrings caught was equal to one-half the total supply from the coasts of the mainland. In 1886, however, this fishery proved a comparative failure.

Before concluding our remarks we would again direct attention to the Bill before Parliament for promoting a better distribution of the common kinds of fish throughout the whole country, and we cannot better show the necessity of special facilities than by referring to the fact that, in cases of large catches, herrings have had to be thrown by thousands into the sea or sold to farmers for manure.

Letters to the Editor.

THE PHYSICAL SOCIETY.

To the Editor of "Industries."

Sir,—In the otherwise adequate report (on page 214) of some words of mine spoken at a meeting of the Physical Society, on the 25th ult., there occurs a slip of some importance. What I said was, that if there were a want of symmetry *both* in the armature *and* in the field magnet poles of an alternate current dynamo, there would result an inequality in the e.m.f. of a period equal to that of the rotation of the machine, though *neither* departure from symmetry if existing separately would occasion such an inequality. Your reporter has made it appear that dissymmetry in either case would have this result.

Yours &c.,
Silvanus P. Thompson.

City and Guilds Technical College,
Finsbury, London, 3rd March, 1888.

PROPOSED LEGISLATION FOR STEAM BOILERS.

To the Editor of "Industries."

Sir,—Mr. Powis Bale's anxiety in his recent letter to convince your readers that he is such a competent authority, that his experience is so great, and his position so "perfectly independent and unprejudiced," is somewhat amusing; but "he doth protest too much."

In his first letter to you, he asserted "that thousands of boilers are in use that ought to have been on the scrap heap long ago;" but, under correction, these "thousands of boilers" have dwindled miserably down to "many such boilers are in use" in his letter in your last week's issue. This may be taken as a sample of the facts he offers for our consideration; but I am sorry to see that he has not yet grasped the fact that "(1) inspection by Board of Trade officials and (2) inspection by boiler insurance companies under Board of Trade direction" are simply synonymous and convertible terms—"six of one and half a dozen of the other." This will no doubt be self evident to the rest of your readers. The proposed Bill speaks of the boiler inspecting societies as delegate societies, and the Board of Trade reserve to themselves, by the proposed Bill, the power to make, rescind, and vary rules with respect to the survey of steam boilers, and will only appoint as delegate societies such societies, companies, or body of persons whose rules for the time being are approved by the Board of Trade officials. Let Mr. Powis Bale explain where the preference lies.

In your issue of the 17th ult. he states, "I have long advocated that all boiler attendants should possess a certificate of competency that they are capable of undertaking the work," and he thinks that a Bill to that effect should be passed. A sufficient knowledge of the subject would have shown him that this opinion is exploded, and that it is no longer put forward by experts. The annual reports of the Assistant Secretary to the Board of Trade would, I think, be ample to show him how completely unnecessary and uncalled for such a piece of legislation would be. By referring to these reports, he will find that Mr. Thomas Gray, the Assistant Secretary, in his first report upon the working of the Boiler Explosions Act, 1882, dated 17th October, 1883, states that "there is no reason for yet assuming that any material diminution in the number of explosions may be expected to result from the systematic examination of and granting certificates to the men employed in working the boilers."

Again, the Assistant Secretary to the Board of Trade reports in September, 1884, that, "as the explosion can be attributed to neglect or ignorance on the part of the boiler attendant in three cases only, or four at the most, there is still no reason for assum-

Digitized by Google

ing that any material diminution in the number of explosions may be expected to result from the systematic examination of, and granting certificates to the men employed in working, the boilers." And again the Assistant Secretary reports in October, 1885: "The smallness of the number of explosions (four) due to ignorance on the part of the boiler attendant still bears out the conclusions arrived at in previous reports, and shows that the risk of explosions generally would not be materially lessened by the introduction of a system making it compulsory for attendants to hold certificates of their fitness for the work entrusted to them." The Assistant Secretary to the Board of Trade reports on the 31st August, 1886, and finally in his last report for the year ending 30th June, 1887, that after an experience of five years of explosions, he has seen no reason to alter these conclusions.

It is evident from these repeated and extremely definite expressions of opinion on the part of the Board of Trade, that the question of certificating attendants may be dismissed from consideration, whatever Mr. Powis Bale and your other correspondents think or state to the contrary. It is unnecessary to add further evidence on the point. It is well known to those who have carefully studied the question that this matter was thoroughly and carefully investigated before the Board of Trade took up the question, and the same decision arrived at.

The recent article in your contemporary, *The Engineer*, simply confirms in the most positive terms the position I have taken up, and says: "There is no approach to a popular demand for Government inspection of steam boilers. The feeling is all the other way. The relations of the Board of Trade with ship owners on all that concerns marine boilers are so unhappy, *that no one acquainted with the facts wishes to see the authority of the Board extended to our factories or our railways.* . . . For ourselves we may repeat what we have often said before, viz., that we are flatly opposed to the idea of Government interference in the matter of boiler inspection." The italics are mine; these quotations will show what assistance your contemporary offers to Mr. Powis Bale and his views. His reference to the article is somewhat curious in view of the fact that boiler attendants are never even mentioned in it. I have now shown what ground Mr. Powis Bale had for his last assertions.

Let me again refer to the annual reports of the Assistant Secretary to the Board of Trade, and we shall then be able to follow the course taken by the Board of Trade with relation to the working of the Boiler Explosions Act of 1882, and the plan which has been adopted to render it nugatory and ineffectual, so that further legislation might be forced upon the country upon that very plea. The first report, issued on the 17th October, 1883, states: "Provision is made in the Act for an inquiry of a more expensive and formal character, but no case has arisen during the year raising any complex or difficult question that an engineer inspector could not deal with, and therefore inquiries of the more formal and more expensive character have not been ordered." This in face of Mr. Carlisle's report, No. 29, so scathingly criticised by your correspondent "Boiler" in your last issue, where the only conclusion "an engineer inspector" could arrive at as to the cause of an explosion was that it was caused by "the excessive strain thrown on the seams, and the flattening tendency of the top of the furnace caused by the sudden contraction of the top of the furnace and flue in consequence of the furnace door being open for a period of from five to ten minutes whilst the furnace was being cleaned, the dampers being open at the same time."

Surely, so far at least as the "engineer inspector" was concerned, a complex and difficult question had arisen, and a "more formal and more expensive" inquiry was undoubtedly required and should have been made. In the Assistant Secretary's report for September, 1884, he again states: "Provision is made in the Act for an inquiry of a more expensive and formal character; but no case has arisen during the year raising any complex or difficult question that an engineer inspector could not deal with, and therefore such inquiries have not been ordered." In October, 1885, he states: "No formal inquiry of the kind provided for by Section 6, sub-section 2, has been held during the year, the preliminary investigation having been found fully sufficient to trace the explosions to their true cause." Again on August 31st, 1886, he remarks: "It has not been found necessary either to institute a formal investigation in any case which has occurred during the year, or to take legal proceedings of any kind under the Boiler Explosions Act;" and, lastly, in the report for the year ending 30th June, 1887, he states that "no formal investigation has been held during the year, the preliminary inquiry having in each case been found quite sufficient to determine the cause of the explosion. This has also been the case in each of the preceding years during which the Act has been in operation; and in some respects it is of course satisfactory that the causes of all the explosions reported upon should have been ascertained without in any instance necessitating the increased expense which a formal investigation before two commissioners would have involved. But, on the other hand, this fact has been attended by one serious disadvantage. By the terms of the Act a court of formal investigation has power to order the costs and expenses of inquiries or investigations, or any part thereof, including therein the remuneration of persons holding such inquiry or investigation, to be paid by any person summoned before it, or by the Board of Trade; but no provision of this kind is made in cases in which only a preliminary inquiry is held. The consequence is that, however gross may have been the neglect or mismanagement of the person responsible for the explosion, there are no means of enforcing payment of any part of the expenses incurred in connection with the preliminary inquiries. These have to be borne by the Government, while the person really to blame finds himself exempt from all liability as regards the costs." Anyone not familiar with the provisions of the Boiler Explosions Act, 1882, might suppose from the manner in which the Assistant Secretary to the Board of Trade harps—in every report he has written—upon the string that "the preliminary inquiry in each case has been found quite sufficient to determine the cause of explosion," that the Board of Trade had no power in such a case to order a formal inquiry, whereas the Bill distinctly states: "If it appears to the Board of Trade, *either upon or without such preliminary inquiry*, that a formal investigation of the causes and circumstances attending the explosion is expedient, the Board of Trade may direct a formal investigation to be held."

Apart from the fact that the conclusions of the engineer inspector not being in many cases either in accordance with the facts or common sense, or at all reasonable to a professional mind—as shown in the case of Report No. 29, for example—and therefore directly at variance with the Assistant Secretary's statements, there is the undisputed fact that many of the explosions were of such a character that it was desirable, from a punitive point of view, to hold a formal investigation, and to saddle the careless owner with the costs.

Had this plain, straightforward, common-sense course been adopted, the number of explosions would have fallen to those which can only be considered as accidental and inevitable. The mere dread of an inquiry of any sort, without fear of fine or punishment, has reduced the number of explosions during the operation of the Act since 1882 no less than 40 per cent. Had the powers of the Act been brought into action, as they ought to have been, the subject would now have been settled, and preventable explosions practically a thing of the past. The question arises—Why have the officials of the Board of Trade not carried into action the provisions of the Act of 1882, and why, instead of instituting ineffectual criminal actions against poor engine drivers, did they not in the many gross cases of neglect and wanton disregard of all precaution, make formal investigations? Formal investigations should be held in every case where blame could be fairly laid to the owner or user of the boiler. That could be often easily decided, without the necessity of a preliminary inquiry; for in many of the cases ample evidence is at once forthcoming. The official mind would know how to make this "more expensive" process so costly that a single experience of its action would send the offender into the bankruptcy court, and his fate would be a sufficient warning to others. The Board of Trade have further powers under the Boiler Explosions Act, 1882, to "cause every such report to be made public in such manner as it thinks fit." This power enables the Board of Trade to publish in the journals of the district where the explosion occurred a short report, with their observations upon the cause. It is a power that has never once been put in force, although it would have had a great and powerful effect, as the infamy that would attach to any reckless, parsimonious owner would have been amply sufficient to warn and deter others. Writing in October, 1885, the Assistant Secretary states that, "There is reason to believe that the publication of the Reports of these investigations is proving of considerable utility. From the frequency of the applications made for them by persons interested in legal proceedings arising out of the explosions, it is evident that they are being generally used in civil actions; and in this way it is likely that the impartial investigations provided for by the Act will tend ultimately to render steam users more careful, and thus to reduce the number of explosions arising from their neglect." For some inscrutable reason, or perhaps for the want of reason, these Reports are not issued until months after the explosion to which they relate. Take the last four, issued simultaneously about the 20th of last month. No. 244 occurred on the 22nd November, 1887; No. 245 on the 25th October, 1887; No. 246 on the 9th November, 1887; and No. 247 on the 26th October, 1887, or about three and four months after the date of the explosion. In many cases this unnecessary delay would entirely destroy their value, and under the most favourable circumstances seriously reduce their value. There would appear to be no reason why such Reports should not be issued within a fortnight of the date of the explosion, if the examinations were conducted and reported upon by capable men, who could of their own knowledge and experience decide as to the cause of the explosion without reference or assistance. A short *résumé* and statement of the cause should then, in such cases as desirable, be published in such papers as might be found desirable, and another powerful agent for the prevention of boiler explosions set in action. If such a report were published, and the costs of a formal investigation cast upon a boiler owner who had been contributory to an explosion, there is little doubt that the Board of Trade would seldom have an opportunity, if ever, of again inflicting such a punishment.

Why have the Board of Trade officials smothered the Act of 1882, and never put its powers in force? What are the objects the permanent officials have in view? Is it the benefit of the steam user, the boiler maker, or the public? Would it be unkind to endorse the opinion of your correspondent "Pro Bono Publico," that it is, to use his own words, "an unwarrantable plot to foist upon the nation a new department, with additional berths for place-seeking officials, in direct opposition to the deliberate opinion of the Select Committee of 1871, and in the absence of any public agitation or demand for such a step"?

Let the steam using public of this realm awake! If they allow the inspection of their steam boilers to pass under the control of the Board of Trade, it will involve an expenditure of £50,000,000, and, at 3 per cent., an annual charge of £1,500,000, independent of the cost of carrying on the inspection, which may be fairly taken at another £500,000. Harassing interference when laying down new plant, and with the working of old, with all the irritation and annoyance due to dictatorial supervision and interference, will be some of the minor troubles that will flow from want of firmness at this crisis. Let your representatives know what your opinions are, and let there be no doubt as to the result.

Yours, &c.,

Manchester, 5th March, 1888. ECONOMISER.

TO THE EDITOR OF "INDUSTRIES."

SIR,—When Mr. Powis Bale advocates the desirability of granting certificates of competency to those entrusted with the care of steam boilers, he only expresses the opinion of many others, myself included. That there are many so-called "cheap men" put in charge of steam boilers, and that they daily jeopardise the lives of thousands, can hardly be denied. The following is an advertisement cut from a leading London daily paper: "Youth, 16, intelligent, abstainer, seeks employment; look after engine and boiler, or any like capacity; no experience." When it is possible for such an advertisement to appear, the wonder to me is that more serious accidents do not occur; but of course we hear nothing of the vast number of narrow escapes which daily take place. If it is necessary for an engineer at sea to have a certificate of competency, why should not a modified one be in vogue on land. It could harm no one, would add to the longevity of the boiler, lessen the coal bill, increase public safety, and improve the status of the men.

Yours, &c.,

A. C.

London, 6th March, 1888.

BOILER EXPLOSION NEAR BURNS' COTTAGE.

ON the 1st inst., about three p.m., a small boiler, which had been erected outside a smithy fronting the road near Burns' cottage, at Alloway, near Ayr, belonging to Mr. William Thomson, exploded. It supplied steam to an engine used to drive lathes, and for other purposes, in the smithy. The boiler, which appears to have been bought second hand, is about 2ft. in diameter, 5ft. 9in. in length, and is plain cylindrical in form, with cambered ends flanged in. The shell is $\frac{5}{16}$in. thick, riveted with one seam running the whole length. There was an unstrengthened manhole 14in. by 10in. It was provided with a safety valve, 2in. diam., loaded to about 48lb. per square inch, a glass water gauge, and other mountings. The boiler was torn in two pieces through the solid plate, close to the one longitudinal seam. No serious injury to any person occurred; but two children who were looking in at the smithy door, and two others who were playing at the back of the smithy, were somewhat cut and bruised. The boiler was not under inspection or insurance. Between the smithy and Burns' cottage a two storeyed house has lately been built, and the upper part of the boiler was thrown over it—rising to a height of about 60ft.—and fell upon the roof of the stable of Burns' cottage 70 yards distant, while the lower half was found in a garden 30 yards away. A hay stack at the back of the smithy was set on fire. The part of the stable nearest the smithy was completely wrecked, and the room where Burns was born, which adjoins the other end, had a narrow escape, as the upper half of the boiler fell through the roof of the bedroom of the keeper of the cottage, which adjoins the well known kitchen. It is only about eighteen months since Burns' cottage was in much risk of being destroyed by fire, owing to the accidental burning of an adjoining house.

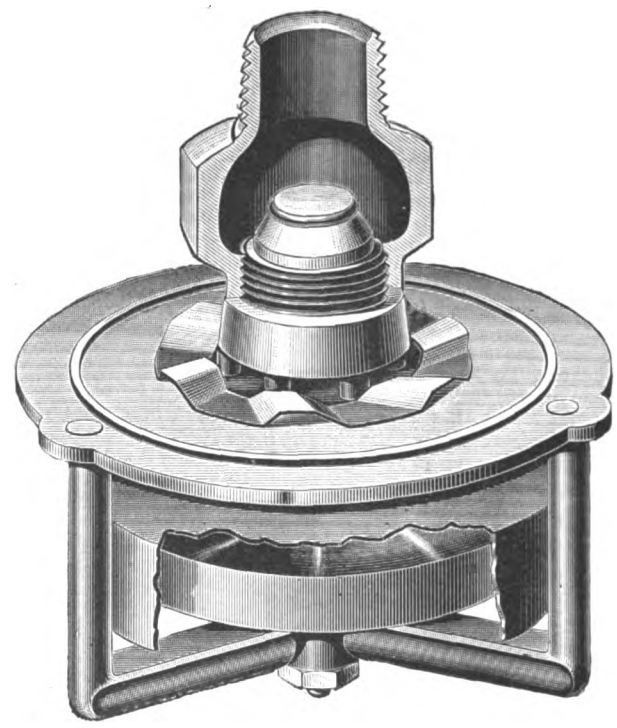
Reviews.

TEXT BOOKS OF COMMERCE: (1) Natural History of Commerce; (2) Technical History of Commerce; (3) Growth and Vicissitudes of Commerce; (4) Recent and Existing Commerce. By John Yeats, LL.D. Third edition, revised and much enlarged. London: GEORGE PHILIP & SON. 1887.

This re-issue of Dr. Yeats' valuable text books of commerce comes at a very opportune time, when the minds of commercial men are being stirred about the necessity for improved commercial education, as there are



Digitized by Google

few better calculated to aid in the creation and development of sound, healthy opinions on the subject. The author gives as a preface to the volumes some extracts from a letter he published in the "Journal of the Society of Arts," showing a few of the difficulties that retard the progress of higher commercial education, and prevent the study of commerce as a science in England, which ought to be carefully studied by all who are interested in the subject. He shows that indifference is the greatest difficulty, and misapprehension of our true position causes it; and he then discusses the various objections which are made to a systematic course of commercial training, and points out that there is really no novelty or specialty in the education of commercial men, beyond what is required in every other calling and profession, and he indicates that the "Science of Commerce" comprises an acquaintance with commercial history and geography, social and political economy, mercantile occupations, goods in all varieties, currencies, weights and measures, bullion and exchanges, transit and transport, insurance and securities of all kinds, consular duties, chambers of commerce, &c., and further, that an efficient commercial man must be an adept in correspondence in several languages, general commercial law, accounts, wages in different countries, international obligations, and means of communication. Dr. Yeats' books do not pretend to include all those subjects; but we have no hesitation in saying that their contents should be known to every commercial man, and we have much pleasure in recommending them, especially to those of our readers who have anything to do with the management of schools. The "Natural History of Commerce" treats of each substance wherever it originates, above ground or beneath the surface, shows what is done with it to make it useful, and indicates where it is bought, sold, or largely consumed. In arranging the subject, the simplest divisions have been adopted—those of the mineral, vegetable, and animal kingdoms; in each of these the products are classified, and scientific terms are attached for wider reference. The "Technical History of Commerce" not only gives a record of economic progress, but furnishes material standards of comparison between nations, and enables us mentally to estimate results; and it shows that with nations, as with individuals, only three conditions are possible for all—they must go forward, retrograde, or perish. A state of balance may perhaps be maintained during the early stages of existence, but not when environments are constantly changing. In the "Growth and Vicissitudes of Commerce," students have opportunities of learning the lessons which are taught by the rise and progress and the fall of nations, and it lays open a wide field for historic and antiquarian investigation. The volume which is likely to be read with the greatest amount of interest is that on "Recent and Existing Commerce," as it appeals most directly to everyday wants, as it shows the merchant where and when what he wants can best be had, and where that which he offers is most likely to be introduced with advantage. It contains a brief review of British industry and trade, a survey of our colonial and foreign relations, a retrospect of the commercial policy of 1840-87, and a section on the natural divisions of commerce, based upon similarity of produce and seasons of shipment, and set forth within well known geographical limits or trade areas. The volume is intended to be a picture of universal industry, in which the most important factors are selected as objects for study and comparison. On the whole we scarcely know of any other four books which will give the merchant more correct ideas regarding what should be his aims and methods than those which we have been very shortly considering.

A Course of Lectures on Electricity. By George Forbes. London: Longmans, Green, & Co.

At a time when we are being inundated with books treating of electrical subjects, we are apt to be somewhat hypercritical, and to judge the latest literary production in this field with greater severity than would be the case if such books were few and far between. Considering the glut in electrical literature, it is a somewhat bold undertaking for a scientist of Professor Forbes' standing to come forward with what is practically a text book on electricity. We have already many text books, and they are all very much alike. We find in them described the same experiments, the same theoretical explanations, and, in many cases, almost the same illustrations. But Professor Forbes' book is an exception, and notwithstanding our objection to the multiplication of electrical books, we are glad he has written this work, because it is eminently adapted to popularise the science with intelligent readers who are not trained electricians. The great fault in many so-called popular books is their scientific inaccuracy. The writers of such books either have themselves not sufficient scientific knowledge, or if they be well up in the subject, they seem to labour under the delusion that nothing like vigorous scientific treatment is admissible in a popular work. In the book under review, all this is different. Not only is the author a thorough master of the science, but he has the wish and the ability to transmit what he knows to his readers in lucid and simple language. The book is the outcome of a series of lectures delivered by Professor Forbes, in the spring of 1886, at the Society of Arts; but he has added to the five lectures one which he delivered in 1884 at the Electrical Exhibition in Philadelphia. Regarding this addition, we will at once say that the book, in our opinion, would be better without it. Certain portions of the last chapter which contains this lecture are practically repetitions of general principles and experiments treated in the previous chapters, whilst the more practical parts referring to dynamo machines, and which are not repetitions, are at the present moment obsolete. It is of very little value to bring forward at the present time such machines as the Alliance, the Wilde, the first Siemens, and the original Gramme machine. During the last four years the science and practice of dynamo construction have far outgrown these early attempts, and if the author considered a chapter on dynamos necessary, he would have done better to re-write it entirely, giving due prominence to modern machines. The rest of the book is, however, excellent. It is divided into five chapters or lectures, with the following titles: Potential and Electromotive Force, Electric Current and Resistance, Magnetism, Electromagnetism, and Electromagnetic Induction. The most interesting part of the first chapter is that where the author deals with the mechanical strains occurring in a dielectric under the action of an electric potential, and the beautiful experiment to show how the strain affects luminiferous ether. When dealing with thermo currents in the second chapter a very neat experiment is given by which a drop of water is frozen under the Peltier effect. In the chapter on magnetism we would specially draw the reader's attention to a quotation from Dr. Scoresby, who in 1824 had already conceived the idea of the chain of magnetic molecules in almost the same manner as Weber and Hughes have done in our time. The rotation of the plan of vibration of a beam of light is also shown by a most elegant experiment with two Nicol prisms and an electromagnet. The illustration, however, is somewhat misleading, because no coils of wire are shown round the magnet, which thus appears to be a permanent steel magnet. In the subsequent chapters the author explains the mechanical inter-action between electric currents and magnets, the electromagnetic induction, the telephone, the Arago disc experiments, and kindred matters. The book can be thoroughly recommended for the general reader in preference to the orthodox text books.

THE HETHERINGTON-DRAPER SPRINKLER.

During the past few years the use of automatic sprinklers for the purposes of fire extinction has become very general. In most cases they are constructed either with a valve or a cap, which is held in position by a bar fastened by means of solder of such a composition that it fuses at a certain temperature. As soon as the fusion of the solder takes place the sprinkler opens and the water is freely poured upon the fire. All sealed sprinklers of this type suffer, however, from one defect, viz., that once opened they cannot be closed until the water is emptied out of the pipes to which they are connected, thereby using more water than is required to put out the fire; and the damage done by this excess of water is often considerable, as in one case the loss from fire was only one-sixth of that arising from the damage done by the water. Our illustration shows an improved sprinkler of American origin, which is being manufactured by Messrs. Hetherington & Co., of Manchester, and which, it is claimed, overcomes this defect. The orifice from which the water is discharged consists of a flat circular seat, on to which a button or mushroom valve is forced by the pressure of the water. The valve has a shank passing downwards, and screwed at its lower end. Just below this orifice a corrugated brass washer is placed, which revolves rapidly when a jet of water falls upon it, thereby distributing the water over a large surface. A short hermetically sealed cylinder made of brass is fitted in its centre with a tube, through which the shank of the valve passes, and lock nuts are placed above and below the cylinder referred to. The latter contains a volatile fluid which readily expands when heated.

The action of the apparatus is as follows: In fixing the sprinkler, it is necessary to determine the temperature —about 140°F.—at which it is to act. The lock nuts on the shank of the valve are accordingly set in such a manner as to lift the valve as soon as the sprinkler has attained the temperature decided upon. The liquid in the cylinder is expanded by the increase of temperature, and the convex covers, which are held at the sides, are forced outwards, thereby actuating the valve through which the water is discharged. The amount of lift of the valve is regulated by the lock nuts. In order to prevent the cylinder from being cooled by the water, a brass shield is placed a little way above it, surrounding the cylinder on all sides, but allowing the air to circulate freely round it. This shield protects the cylinder not only from the water discharged from its own sprinkler, but also from adjacent ones. As soon as the temperature of the air falls below the point at which the sprinkler is set to act, the liquid inside the cylinder begins to resume its original bulk, and the pressure of the water on the top of the valve closes it. As soon as the valve is closed, the apparatus is quite ready to act again if required, which is an important improvement in this design. In some tests made with shavings, arranged in such a manner as to allow the flames to spread only slowly, the fire was extinguished and the discharge of water stopped in three minutes from the time of kindling. A quantity of straw soaked with paraffin, lighted at one point, was extinguished and the water cut off in 2½ minutes, the portion burnt being about 12ft. in diameter. We have already referred to the advantage of cutting off the water as soon as the fire is extinguished; and with the additional advantage of being simple in construction and very strongly made, this sprinkler should prove a very efficient means of putting out fires before they can become serious.

FARM HOMESTEADS OF ENGLAND.

By Professor T. J. Elliot.

This is a subject of great importance, both to the land owners and the land occupiers of England. For without buildings the former could not let his land; and unless the homestead is well designed and suitable for the purposes of the farm, the tenant will find it a difficult matter to carry on successfully the various operations of farming. It is, therefore, a necessity to both. Years ago—say some twelve or fifteen—the homesteads of England had the most careful attention paid to them by some of our best architects and agricultural engineers. But those were days of prosperity, when, owing to keen competitions, farms were not only let well, but in many cases fictitious rents were easily obtained. The landlords receiving high rents were in a position to spend money in the erection of large, and in some instances expensive, farm homesteadings. Now, however, times have changed, and the change has been of such a radical character that the landlord's income barely provides him with the means for living, much less allowing him a margin to spend on new buildings, or even in the repairs of old ones. And for the last few years little attention has been paid to their condition.

The matter thus turns upon the questions: (1) What are the considerations, so far as economy with efficiency is concerned, which must guide the agricultural builder in designing and erecting new homesteadings; and (2) from what source in future can the impoverished landlord of the present day obtain the means for supplying his tenants with necessary building accommodation? Before answering these questions it will be well to understand distinctly what agriculture really is. Let us then look into it. In the ordinary course of farming we find that it is necessary, in order to maintain the proper chemical and physical condition—or, in other words, the fertility—of the soil, to grow a succession of crops differing not only in their character and bulk, but also in the means required for their profitable conversion. Nature, through its vast store room, the soil, aided by artificial means, supplies the agriculturist with the raw material in the form of plant food. But before this plant food can be used for the benefit of the farmer, several acts of husbandry are required for its profitable utilisation. And again, the produce thus obtained requires further preparation before it can be realised, viz., in dressing or preparing the corn for market, and in the conversion of the hay, root, and green crops into meat. We thus see, therefore, that the art of agriculture is neither more nor less than the manufacture of raw materials into food for man and beast. In other words, agriculture is a manufacturing business, and agricultural homesteadings are the factories belonging to the trade of farming.

We are now in a position to answer the first question by saying it will be the duty of the architect or agricultural engineer to supply the farm with buildings in the simple form of a factory; and if he takes for his guide the class and style of buildings used in manufacturing trades other than that of agriculture, he will find by comparison that they are less pretentious as regards design, although equally sufficient for the purposes for which they are erected. There has always been a tendency to introduce a great deal of unnecessary display into the designs for farm buildings. Some would say, "But all this is necessary, seeing that they are so much exposed to the criticisms of passers by, and if ugly ones were built, they would mar the beauty of the surrounding country." The answers to these observations are: (1) Place your farm on a site not at all conspicuous; and (2) should such a site be impossible to obtain, build them neatly and plainly, and relieve them by a little judicious planting of trees near them.

The architect having done his part by reducing to a minimum the cost of the homesteading, it devolves upon the owner—assuming he is a poor man—to look around and see what are the helps at his disposal so as to obtain the amount of capital required. These may be enumerated as follows: (1) He may raise money by means of a mortgage on the freehold of his property; (2) he may apply for assistance to such societies as the General Land Drainage and Improvement Company, who, by a private Act of Parliament, are authorised to advance money for improvements of this sort, and can if necessary make a rent charge on the freehold of the estate extending over a period of thirty-one years; (3) should the estate be entailed, the owner may make use of Earl Cairns' Settled Land Act, by which a portion of the estate may be sold for the improvement and benefit of the remainder. In conclusion, it may be of interest to many if I can show the proportion of rent per acre per annum received by the landlord for his land, and how much of the annual rent is swallowed up by the homesteading.

Assume a farm of mixed arable and pasture land of two hundred acres, worth 30s. per acre. Two hundred acres at 30s. equals a rent of £300 per annum, allowing about 7 per cent. of the rent to be required annually for repairs, and that the value of land is at "par"—or equivalent in value to consols. The fee simple value of the farm would be worth 28·5 years' purchase on the rent. Thus £300 × 28·5 years = fee simple value of holding, £8,550. A house, a set of buildings, and three cottages would be required, and would cost £1,500; making roads, fencing, and water supply would cost £400; total, £1,900. The value in fee simple of land taken by itself = £6,650. Land in its natural state, without being chargeable with repairs of buildings, is worth 33½ years' purchase. Therefore £6,650 (fee simple value) divided by 33½ years' purchase is equal to £199. 10s. net rent per annum, or nearly 20s. per acre over the two hundred acre farm. The land therefore produces to the landlord 20s. per acre; the buildings swallow up 10s. per acre; making the rental value 30s. In a future article I will endeavour to show that the landlord gets more in comparison for his land per acre as the size of the farm increases. I will also compare the loss per acre which the landlord sustains on the buildings, with the amount he would be charged for an advance made to him by any of the loan societies for the purpose.

MANGANESE STEEL AND ITS PROPERTIES.

At the ordinary meeting of the Institution of Civil Engineers, held on the 28th ult., the President being in the chair, two papers were read on Manganese Steel, viz.: (1) "Manganese in its Application to Metallurgy," and (2) "Some Novel Properties of Iron and Manganese," both by Mr. Robert Abbott Hadfield, Assoc.M.Inst.C.E.

The first paper commenced with a statement that Hadfield's Steel Foundry Company, Sheffield, was, some time ago, in search of a material suitable for making castings which should possess hardness and toughness, as ordinary steel castings did not combine these qualities. Cast steel, unlike cast iron, could not be "chilled;" this was a great disadvantage, for although steel castings of ordinary temper might be exceedingly tough, as soon as hardness was reached, by an addition of carbon or other elements, the toughness rapidly decreased, the material became brittle, and did not possess the intense hardness of chilled iron. Even cast steel with more than 2 per cent. of carbon was comparatively soft; and whilst chilled iron cylinders, 0·79in. in diam. by 1in. long, remained unaltered under a load of 100 tons per square inch, cast or forged steel cylinders, if unhardened, shortened from 15 to 40 per cent., according to temper. If molten steel of any temper, as hitherto made, was run into an iron mould used for making "chilled rolls," when cold the grain of the casting would be somewhat closer than if cast in sand, but still quite soft, easily indented, and the metal might be turned in ordinary lathes. The same article made from cast iron of suitable mixtures would be intensely hard on the surface. Here, then, was a drawback to cast steel, as although it might be hardened when immersed in water or oil, this application was impracticable to the many irregular forms dealt with by steel founders; besides, the intense strains brought to bear by such hardening process would cause the articles to crack and break into pieces. It had therefore been thought that an account of the results noticed in connection with the material termed "manganese steel," might prove of interest to the Institution of Civil Engineers, particularly as it offered advantages over ordinary steel in some points. Moreover, it seemed to afford new fields for investigation in metallurgy, since many of the results noted in its production were contrary to general experience. Laws, hitherto accepted and considered to be well defined, were apparently set on one side, and it was possible therefore, by the facts being discussed, to throw light upon the subject. The field for investigation and extension in the knowledge of the alloys of iron was very wide, but as yet comparatively little had been done. The knowledge of steel had so far been principally confined to carbon steel or alloys of iron and carbon, about nine-tenths of the steel made being of this class. The first paper principally dealt with and described the experiments; the physical properties noticed in the material, and the conclusions to be drawn therefrom being more particularly defined in the following one. Special attention was drawn to what essentially constituted the peculiarity of manganese steel. Whilst the belief hitherto held, that steel became brittle and comparatively worthless when the manganese exceeded 2·75 per cent. was correct, it had now been proved that by adding more of the same metal, so as to obtain in the material under treatment not less than about 7 per cent. manganese, the result was a new metal. The apparent paradox thus took place, that whilst manganese alloyed with iron, if present in the proportion of not less than 2·75 and up to about 7 per cent., gave a very brittle product; when its proportion was increased to not less than 7 and up to about 20 per cent., the result was a material possessing peculiar and extraordinary strength and toughness. The brittleness of the cast material seemed to partake more of the nature of glass, or other similar substance, than of a metal such as steel. Cast bars, about 2⅝in. square in cross section, 30in. long, were supported upon bearings 2ft. apart, and broken under hydraulic pressure, the breaking load being carefully noticed in each case. One of these specimens, containing 0·37 per cent. carbon and 4·45 per cent. manganese, was fractured under a pressure of 3¾ tons; whilst a bar of ordinary cast iron stood 12 tons, and the higher percentages of manganese, 17 and 20 per cent. respectively, stood 29½ and 38 tons. Another instance was afforded by a bar casting, containing 4·73 per cent. manganese, being dropped from a height of 3ft. to 4ft. on a floor paved with cast iron, when fracture occurred in two or three parts of the bar at the same time, showing its extraordinary fragility. Pieces from another specimen, containing 0·48 per cent. carbon and 4·9 per cent. manganese, though exceedingly ductile when hot, in the cast state when cold could be reduced by a hand hammer to fine powder, no cohesion seeming to exist between the particles. On the other hand, a specimen of forged material, containing 13·75 per cent. manganese and 0·85 per cent. carbon, when water toughened, had a tensile strength of 65 tons per square inch, with 50·7 per cent. elongation; and another specimen, 69 tons and 46 per cent. respectively. In the latter case, the tensile load, calculated on the area of the bar at the moment of fracture, was equal to 102 tons per square inch. The combination of hardness and toughness found in this material led to experiments as to whether edge tools could be cast from it. These tools, whilst not equal to those made of forged, hardened, and tempered steel, had afforded some remarkable results. The author exhibited some castings as they left the moulds, the cutting edges merely being ground up, and neither hardened nor tempered. These included a cast axe, which had chopped through cold iron, along with the pieces of iron cut through. Another axe of the same quality, which had been used for over two years, readily shaved off the hair on the back of the hand; and cast razors had been made which, whilst not equal to those of ordinary steel, had done fairly well. A cast adze and chisel for wood were also shown, both of which had been constantly in use for over two years, and had cut through the hardest knots and hard wood. Manganese steel possessed toughness to resist severe usage, and hardness to prevent permanent set without bending or buckling. Some of the tests showed that the material had these qualities in a most remarkable degree. The tests were made with an ordinary drop tup, sliding between steel rails fastened to strong timber supports, which was allowed to fall on Browning's coupler castings. The tup weighed 2321lb., and the drop could be varied from 1ft. to 27ft. Each casting was placed vertically, and the tup allowed to fall upon the jaws, the permanent set being carefully measured after each blow. Exact particulars of the remarkable results obtained from the manganese steel were given. The couplers tested were an American malleable iron casting; a manganese steel casting, containing 9·37 per cent. manganese, tested just as cast; a tough mild steel casting, containing 0·25 per cent. carbon, having a breaking strength of 32 tons per square inch, with an elongation of 30 per cent. on 2in.; also two manganese steel castings, water toughened, containing respectively 9·75 and 14·25 per cent. manganese, which were unbroken, notwithstanding that the latter had more than 300 foot-tons of energy expended upon it. The author directed attention to the peculiar hardness of this steel, both in its cast and in its forged condition. The specimens were so exceedingly hard that it was scarcely possible to machine any of them on a practical scale; the hardness was most intense in the cast material containing 5 to 6 per cent. manganese, which no tool would face or touch. A gradual decrease then occurred, and when about 10 per cent. was reached the softest condition was attained. Then an increase again took place, and at 22 per cent. it was very hard, still not so much so as in the 5 per cent. specimens. After passing 22 per cent. the cause of hardness became more complicated, owing to the presence of more carbon, 2 per cent. and upwards; in fact, the material began to partake more of the nature of cast iron, but it had greater transverse strength. A test bar, with 14 per cent. manganese, which elongated 44·5 per cent. without fracture, and had a tensile strength of 67 tons, was put under a double geared 18in. drill. Over an hour was occupied in drilling one hole ½in. in diameter by ⅝in. deep, during which time fifteen to twenty holes of the same size could have been easily drilled in mild steel. Similar results from specimens sent to different engineering firms confirmed the above, yet this specimen could be indented by an ordinary hand hammer. Although, when being turned, it appeared harder than chilled iron, its softness was particularly noticeable when testing the material for compression. Specimens of 10 per cent. manganese steel, 1in. long by 0·79in. in diameter, notwithstanding they required several days' preparation in the lathe owing to their hardness, yet under a compression load of 100 tons per square inch shortened 0·25in., and the harder kind 0·1in. to 0·13in. Chilled iron or hardened steel would stand this test without any alteration. Attention was also directed to the fact that a load of 27 tons per square inch, which in ordinary mild steel would cause fracture, and an elongation of 30 per cent on 8in., only elongated manganese steel 0·53 per cent. on the same length. A hammered manganese steel bar was compared with a best quality steel railway axle of the same diameter as the manganese steel bar. The results of the tests showed that on the manganese steel bar or axle an energy of 498 foot-tons produced total deflections of only 39½in.; whereas on the special steel axle an energy of 348 foot-tons produced total deflections of 105¼ inches. Assuming the manganese steel to have been capable of resistance without fracture, and the deflections to have continued in the same proportion, an enegy of no less than 1360 foot-tons would have been required to effect the same deflections that 348 foot-tons produced on the special or carbon steel axle. The peculiarly combined toughness, hardness, and stiffness of manganese steel, either cast or forged, were very clearly brought out in these tests. The material therefore seemed well adapted to resist severe stress before fracture, and yet at the same time to show very slight alteration under stress. The author stated that the results having been often anomalous as compared with ordinary steel, special care had been taken to thoroughly verify each experiment. If contradiction sometimes occurred, it might be partly explained by the want of knowledge requisite in dealing with a new material. In conclusion the author referred to the inadequacy of the explanations offered with reference to some of the peculiarities noticed in manganese steel. His remarks were therefore in many instances offered only in the nature of suggestions for the consideration of scientific and metallurgical authorities. The field for investigation was very wide, and his object had been to describe the experiments made with care and exactitude.

In the second paper considerations were offered as to the causes of the results noticed in the previous one; but before proceeding to these the author remarked that some decision ought to be arrived at upon the exact meaning of the word "steel." Numerous combinations or alloys were being manufactured to which this term was given. It had hitherto been applied to malleable alloys or mixtures of iron and carbon, and the author pointed out some peculiar features in alloys or compounds of iron and manganese which also possessed a steel-like nature. In some correspondence with the author, Mr. R. Mushet wrote: "Your material is really not steel, but an alloy in certain proportions of iron and metallic manganese containing

Digitized by Google

also carbon, but as little of that as you can help. Your alloy possesses some of the properties of steel, and it is to a certain extent a substitute for steel, just as brass, which is not copper, is nevertheless a substitute for copper." Whilst there was much to be said for this view, it was open to consideration whether iron formed actual compounds or mere mixtures or alloys. Steel had been defined by Bresson as "a particular state of iron produced by its union with bodies the nature of which can vary. There are three classes: first, steels composed of iron and carbon; second, those of iron, carbon, and a third body; third, those formed of iron and another body which is not carbon." It would be seen from the properties of manganese steel that this view was correct, and that bodies other than carbon could play a constituent part in the conversion of iron into steel; in fact, Faraday, long ago, was reported to have made an alloy of iridium and iron which possessed steel-like properties, although no carbon was present. When plunged in water the behaviour of manganese steel was quite different to that of ordinary carbon steel, no hardening action taking place. Water certainly caused the material to become stiffer, but in a different degree to hardened carbon steel; for a piece of manganese steel after such treatment was slightly more easily touched by a file; therefore the process was termed water toughening. The increase in stiffness was marked, the tensile strength rising from 40 to 60 and in some cases over 70 tons per square inch; but this was not a mere stiffening or hardening effect in the ordinary sense of the term, for in carbon steel such rise was invariably accompanied, when the cooling medium was water, by a considerable decrease in the ductility or elongation, whereas, in manganese steel, just the opposite effect was produced. When, however, the samples contained below about 7 per cent. manganese, this treatment seemed to exercise little or no influence, and the material was comparatively valueless where toughness was requisite. After a large number of tests on the action of heat and sudden cooling upon this material, it had been found, generally speaking, that the higher the heat of the piece treated, and the more sudden and rapid the cooling, the higher would be its breaking load and the greater its toughness or elongation. This was very apparent from the results of six bars which were heated as uniformly as possible to a yellow heat, and plunged into water of 72°F., which gave breaking loads varying from 57 to 63 tons per square inch, and elongations of 30·8 per cent. to 50 per cent. For comparison, another test bar of the same material was heated in precisely the same way and degree, but plunged into water at a temperature of 202°F., when the results were only 53 tons and 32·8 per cent. The more rapid cooling of the other test bars was evidently the cause of their superiority, the chemical composition of all being the same. It was also thought that sulphuric acid, being a rapid conductor of heat, might give good results as a cooling medium. The experiment was therefore made with a bath consisting of equal volumes of water and sulphuric acid, and on 8in. the extraordinary elongation of 50·7 per cent. was reached with a breaking load of 65 tons, the bar being thus drawn cold 4½in. before fracture. Another specimen on a 4in. length gave 56·75 per cent. Various experiments were made to show the influence of manganese upon forged iron, the former varying from 0·83 to 21·69 per cent. under different modes of treatment. It was found that oil had a beneficial effect on the metal, but not equal to either water or sulphuric acid; this no doubt was due to its lower conductivity. It was also noticed that the operation of merely heating the forged test bar to a yellow heat and cooling it in air had a very beneficial effect, the elongation in most instances being increased to 15 and 20 per cent., the tensile strength also rising 8 or 10 tons per square inch. It was not easy to understand the action of the water quenching process. As explained by Chernoff, the effect of oil tempering on ordinary steel was to produce a metal of fine grain, which possessed much greater strength than open, coarse grained steel. If, however, forged manganese steel possessed any difference of structure after being heated and water toughened, it was rather in the direction of a more open than a closer grain. But the most puzzling case in the author's experience was that of cast toughened specimens containing 9 per cent. manganese, at which percentage the crystallisation was very peculiar. An ingot 2½in. square in cross section and 2ft. long was cast in an iron mould. When cold, a piece was broken off under four blows of a steam hammer. The fracture showed the usual peculiar form of the 9 per cent. material, a form which to outward appearance was unchanged by any heats short of the melting point. The other piece was re-heated to a yellow heat and water quenched. In this the toughness was increased in a remarkable manner, ten blows of the steam hammer being required to break the bar, although the appearance of fracture was unchanged. This material possessed the peculiar property of being almost entirely non-magnetic, which was curious, seeing that iron was present in amounts eight or nine times greater than the manganese. An approximate idea of the amount of manganese contained in steel might be formed by passing a magnet over specimens; as the percentage of manganese increased, the effect of the magnet diminished. Upon reaching about 8 per cent. there was no attraction in the bulk, though fine drillings were influenced; but when 20 per cent. was reached, a magnet capable of lifting 30lb. of ordinary steel or iron would only lift pieces weighing a few milligrams. No advantage was gained in ordinary steel by adding more than 1·5 to 1·75 per cent. of carbon, an amount above this not producing steel with any greater degree of hardness. Hence, the analysis of the majority of Sheffield carbon tool steels showed not more than 1¼ to 1½ per cent. carbon; at these tempers the point of saturation, so to speak, seemed to have been reached, so that carbon itself could hardly be the sole cause of hardness. The question, therefore, of the crystallisation or structure became of great importance. No one could well mistake the difference of fracture in wrought iron and in mild steel, though both might give by analysis the same percentage of iron; in fact, wrought iron might even contain more carbon than mild steel, and yet the structure in no way resemble that of the latter. It was apparent, therefore, that iron did vary its form or structure. This was noticed by steel-casting manufacturers, who by judicious treatment could increase the elongation of steel as cast from 8 or 10 per cent. up to 30 per cent. Professor Barrett had noticed another point of difference between this and carbon steel. Manganese steel, when cooling, did not give any "after-glow." A Sheffield firm also reported that in rolling a length of 800ft. in one piece of this wire, the finer it became the more it seemed to retain the heat—in fact it appeared to gather heat in the process. In conclusion, the author again contended that some understanding should be arrived at as to the meaning of the term "steel." In the past this word had sufficed well enough for an alloy or compound of iron and carbon; but the latter was in many instances now being replaced by other elements, such as manganese, chromium, silicon, or tungsten. The author held that steel was but a particular state of iron produced by the union of that metal with bodies the nature of which might vary.

The papers were illustrated by an extensive collection of samples of manganese steel, and of ordinary steels, which will remain on view at the Institution for a few days. The discussion on these papers was resumed on Tuesday last.

THE CHEMISTRY OF THE LEADEN CHAMBER.

Recent investigations upon the action of sulphurous acid on nitrous acid, and on the compounds derived from sulphuric acid and containing nitrogen, have tended to clear up the chemical changes which take place in the leaden chamber in the process of the manufacture of sulphuric acid; but we are as yet far from a complete solution of this complicated problem. For many years past, there has been considerable discussion and much experimental investigation on the nature of the so-called crystals of the leaden chamber, and the part played by the oxides of nitrogen in the formation of sulphuric acid. Until comparatively recently it was believed that nitric acid was the only substance capable of converting the sulphurous acid gas into sulphuric acid, and that the nitric peroxide formed in this change subsequently underwent decomposition with the water or steam present in the chamber, re-forming nitric acid and nitric oxide, which in presence of air was immediately oxidised to nitric peroxide again. These changes can be represented by the following chemical equations:—

$$SO_2 + 2\left.\begin{matrix}NO_2\\H\end{matrix}\right\} O = \left.\begin{matrix}SO_2\\H_2\end{matrix}\right\} O_2 + 2NO_2 \quad \ldots\ldots(1)$$

$$3NO_2 + \left.\begin{matrix}H\\H\end{matrix}\right\} O = 2\left.\begin{matrix}NO_2\\H\end{matrix}\right\} O + NO \quad \ldots\ldots(2)$$

$$NO + O = NO_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots(3)$$

Winkler subsequently brought forward evidence to show that in presence of sulphuric acid nitric oxide was not oxidised to nitric peroxide, but that nitrous anhydride N_2O_3 was produced, and agreed with the explanation of the change first suggested by Weber, that the sulphurous acid was oxidised by the nitric acid, forming at the same time nitrous anhydride, which was able to convert another portion of sulphurous acid to the higher oxide, becoming thereby reduced to nitric oxide. The nitric oxide, according to him, was then oxidised by the air to nitrous anhydride, which was then capable of again reacting with a fresh quantity of sulphurous acid. These changes may be summed up in the equations:—

$$2SO_2 + 2\left.\begin{matrix}NO_2\\H\end{matrix}\right\} O + H_2O = 2\left.\begin{matrix}SO_2\\H_2\end{matrix}\right\} O_2 + N_2O_3 \ldots\ldots(1)$$

$$SO_2 + N_2O_3 + H_2O = \left.\begin{matrix}SO_2\\H_2\end{matrix}\right\} O_2 + 2NO \ldots\ldots(2)$$

$$2NO + O = N_2O_3 \quad \ldots\ldots\ldots\ldots(3)$$

The crystals which form in the leaden chambers where there is an insufficient quantity of steam or water present are believed by many chemists to be an intermediate product of the change, and they have been examined from time to time, and prepared in different ways, with a view of throwing some light on this question. Weltzien, many years ago, proved that a white crystalline compound was formed when nitrous anhydride was passed into sulphuric acid, and that its composition might be expressed by the formula $H(NO)SO_4$. Nitric peroxide also yields a similar crystalline compound with sulphuric acid of the formula $2H_2O.3SO_32NO_2$. De La Provostaye found that liquid sulphurous acid and nitric peroxide also yield a crystalline compound $SO_3.SO_2.2NO_2$, and Brüning, from his analysis of the chamber crystals, attributed to them the formula $N_2O_32SO_3$. They have also been produced when red and fuming nitric acid is added to concentrated sulphuric acid, when a mixture of nitric oxide and air is passed through sulphuric acid, and when sulphurous acid gas is allowed to act upon concentrated nitric acid, or a mixture of nitric and sulphuric acids.

From the experiments of Ramsay and Cundall, it seems probable that nitrous anhydride cannot exist in the gaseous state under the conditions given in the leaden chamber, but that it must be regarded as a mixture of nitric oxide and nitric peroxide; while Professor Lunge maintains that nitrous anhydride in passing into the state of gas is only partially dissociated. Lunge further contends that oxygen with an excess of nitric oxide forms mostly nitrous anhydride; but when excess of oxygen is present and both gases are dry, nitric peroxide is the only compound formed. In the presence of water, nitric oxide with an excess of oxygen, according to the same investigator, is altogether converted into nitric acid, while when nitric oxide and oxygen meet in presence of concentrated sulphuric acid no nitric acid or nitric peroxide is formed, but nitrosyl sulphuric according to the equation:—

$$2SO_2(HO)_2 + 2NO + O = 2SO_2(HO)(NO_2) + H_2O.$$

Lunge and Naef have also shown that under ordinary conditions the back chambers contain N_2O_3 and not NO_2, and they are of opinion that nitrous anhydride and not nitric oxide is the oxygen carrier in the vitriol chamber process. The reactions expressing the change, according to them, will be

$$2SO_2 + N_2O_3 + O_2 + H_2O = 2SO_2(OH)(NO_2) \ldots.(1)$$

$$2SO_2(OH)(NO_2) + H_2O = 2SO_2(OH)_2 + N_2O_3 \ldots(2)$$

These reactions, Professor Lunge considers, are modified in the first part of the chambers by the excess of sulphurous acid which is there present, and in the last part, where there is little or no sulphurous acid. The amount of water present also affects the changes which take place. He is also of opinion that no nitric peroxide can be present in the chambers when worked under normal conditions, and that any theory as to the reactions which take place, based on this assumption, is erroneous. In dry places nitric peroxide may be formed, and nitric acid if water is present; and the latter will then convert sulphurous acid directly into nitrosyl sulphate, thus:—

$$SO_2 + NO_2OH = SO_2(OH)(NO_2).$$

Lunge also considers that a considerable amount of nitric oxide is formed in the earlier chambers, owing to the denitration of the nitrosyl sulphuric acid by excess of sulphurous acid, thus:—

$$2SO_2(OH)(NO_2) + SO_2 + 2H_2O = 3SO_4H_2 + 2NO$$

and that the nitric oxide at once reacts with the sulphurous acid forming a further quantity of nitrosyl sulphate in the following way:—

$$4SO_2 + 4NO + 3O_2 + 2H_2O = 4SO_2(OH)(NO_2)$$

No nitric peroxide is thus formed, so that the principal changes which take place consist in a condensation of nitrous anhydride, water, sulphurous acid, and oxygen, to nitrosyl sulphate, or of nitric oxide, water, sulphurous acid, and oxygen, to the same compound. Nitrous anhydride is then again formed by the action of water on the nitrosyl sulphate. In the discussion which followed the reading of this paper at the Chemical Society, Dr. Wright stated that he was inclined to believe that sulphurous acid was capable of reducing the higher oxides of nitrogen to a lower state than nitric oxide, and that nitrous oxide and possibly nitrogen itself were also produced. Hjelt was the first to point out that the loss of nitric acid during the manufacture of sulphuric acid was due in a great measure to the presence of arsenic in the pyrites employed, and that in the Gay-Lussac tower, part of the nitrous acid is reduced by the arsenic in the sulphuric acid to nitric oxide. Some other cause than this must occasion loss, as when brimstone or other non-arsenical sulphur is used there is still a necessity for replenishing the chamber with nitric acid vapours; and Lunge, in his paper "Zur Theorie des Blei-Kammer Prozesses," recently communicated to the German Chemical Society, affirms that sulphurous acid does reduce nitric oxide to nitrous oxide both in the chamber and in the Gay-Lussac tower. A considerable loss of oxides of nitrogen is also caused when too much nitre is employed, as then a much larger proportion of nitric peroxide is formed; and when there is a deficiency in the amount of nitre employed, nitrous oxide, nitric oxide, and nitric acid are formed, and loss is occasioned.

Raschig has recently investigated the action of sulphurous acid on nitrous acid, and has shown that when neutral solutions of a nitrite and sulphite be mixed, a salt, which he terms a nitrilo-sulphonate, is formed, and thus on boiling with water is decomposed, forming an amido-sulphonate. The nitrilo-sulphonate also in presence of dilute sulphuric acid yields a salt which can be looked upon as an imido-sulphonate. Hydroxylamine also reacts with sulphurous acid, forming the same amido-sulphonic acid; and H. Raschig considers that some of these nitrogen sulphuric acids may be formed, when free nitrous and sulphurous acids mix with one another; they may therefore be intermediate compounds in the chemical changes which occur in the leaden chamber. He has not obtained any direct evidence in support of his views, and Professor Lunge, although admitting that nitrous oxide is formed by the reduction of nitric oxide by sulphurous acid, does not consider that these compounds of Raschig play any part in the change. Professor Lunge, in the paper already alluded to, draws attention to the fact that any light thrown on the chemistry of these complicated changes cannot be expected to materially benefit the vitriol manufacturer, as the practical conditions for obtaining the best yields are now known, so that there is only a theoretical interest attached to the points which are now under discussion.

ENGLISH CHINA, OR TENDER PORCELAIN.*

The Chinese as a nation long possessed the secret of manufacturing a species of pottery differing from all other kinds in being semi-transparent. The secret of its production, however, was not discovered by Europeans until the beginning of the eighteenth century, when Böttcher, of Meissen, made the first European porcelain, and founded the manufacture of Dresden china. But England was not far behind in the solution of the problem, and a few decades later we find the manufacture of translucent pottery an established industry at Bow, whence the process was removed to Derby, ever since then renowned as a seat of china making. The methods discovered and adopted by the two nations are, perhaps, good examples of their characteristic qualities. By the employment of laborious research and unflagging application, Böttcher, after innumerable trials, imitated the Chinese, and made an article in every respect similar to theirs. The English potters, however, proceeded by original methods, and arrived by one happy stroke of genius at a material having the same translucency as true Oriental porcelain, whilst at the same time possessed of properties that have enabled our native potters to lavish upon it great beauty of finish and wealth of ornament. The single discovery whereby vessels of porcelain were made almost at a bound accessible to the poorest classes was the employment of bone ash, which, when added in due proportion to kaolin and ground china stone, imparts, under the influence of fire, the semi-transparency characteristic of porcelain ware. The effect thus gained, independently of chemistry, by the use of bone earth, has ever since remained to a great extent unexplained, or, at any rate, little understood by the writers of the few works on pottery manufactures, and we find it stated that the "phosphoric acid of the bone ash diffuses itself at a high temperature through all the materials, uniting them into a translucent enamel, which, being less apt to shrink and lose its form than the hard china body, may be baked in larger kilns, and with less risk of loss to the manufacturer;" and again, it is stated that "English china is rendered translucent by the addition to a pure plastic clay of a considerable proportion of glass forming materials, but the proportion is so regulated that, although the ware does not require excessive heat for its firing, its plasticity is sufficient to facilitate manipulation; moreover, the balance of fusibility and plasticity is so adjusted as to allow the introduction of sufficient calcic phosphate to reduce the shrinkage of the ware to a minimum, and at the same time greatly to add to its brilliancy. . . . The translucency of English china is due to the fusion of the felspar contained in the Cornish stone. The calcic phosphate performs many useful functions. In addition to reducing shrinkage, and enhancing the whiteness of the ware, it enables it by its infusibility to stand the fire requisite for the vitrification of the felspar, and adds lightness without materially affecting transparency." Here then we find calcic phosphate and bone ash used almost, if not quite, as synonymous terms; in the first case the phosphate is said to "diffuse itself," forming an "enamel" with the other ingredients; in the second it is said to impart infusibility, lessened shrinkage, and greater lightness to the ware, and the translucency is attributed to the felspar. The writers appear to have overlooked the double part which bone ash plays in the fabrication of porcelain. Very simple experiments will show that bone ash and phosphate of calcium (lime) are two very different materials when regarded from the potter's standpoint. Experiments made in a biscuit oven by the author, with the kind permission of Mr. John Hudson (Messrs W. Hudson & Co.), of Longton, throw considerable light upon the function of bone ash in china making. A number of mixtures were submitted to the oven during ordinary firings: (1) Bone ash, 7 parts; china stone, 4½ parts; kaolin, 4 parts. This, which represents the usual china mass, was mixed with water and moulded into a small article, and after drying it was fired. The result was a good translucent specimen of china. (2) In another experiment the following ingredients were used: 7 parts of pure calcium phosphate, with kaolin and china stone as before. The outcome was now a sample of white stone ware, quite devoid of transparency, which result effectually demolishes the theory of diffusibility and enamel formation on the part of the phosphate. (3) In this instance 5 parts of calcium phosphate were employed, with the addition of 2 parts of calcium carbonate (equal to $1\frac{1}{10}$ parts of calcium oxide or lime), and the same proportions of clay and stone as before. The product was true semi-transparent china, equal in all respects to ordinary china, as far as could be judged from the small specimen. Trial No. 2 therefore seems to show clearly that china does not owe its transparency, to any preponderating extent, to the china stone, although of course the stone must have some effect in this direction. Experiment No. 3, on the other hand, establishes the great effect exerted by the lime in bone ash in producing translucency.

The function of calcium phosphate still required elucidation, and much light was thrown upon the subject by similar trials in the biscuit kiln, using phosphate of aluminium instead of phosphate of calcium. Pure phosphate of aluminium, prepared without the use of alkaline salts, behaves exactly like pure calcium phosphate in the blow pipe flame and biscuit oven, being apparently quite unaffected. Either of these substances made by precipitation with sodium phosphate fuses readily, even after considerable washing, the liquefaction being produced by small traces of alkali obstinately retained by the precipitate. The fusibility of bone ash cannot be so explained, and is doubtless due to the silica. This constituent is not present in the original bones, but is derived from the mill stones and other sources; it is frequently present to the extent of 5 per cent., or even more, in potter's bone ash, with which the experiments were made. Using pure phosphate of alumina 7 parts, clay and stone as before, there was obtained neither porcelain nor stone ware, but a semi-fused and distorted object, translucent in an inferior degree, and very far from possessing the necessary rigidity in the fire. When 5 parts of phosphate of aluminium and 2 parts of calcium carbonate (equal to $1\frac{1}{10}$ parts lime) were substituted for the 7 parts of aluminium phosphate, the result was the same, but the translucency was a little greater, and the fusibility still more apparent. Evidently, then, aluminium phosphate cannot be employed in place of calcium phosphate, and the effect of the latter upon china must be due to other properties than its infusibility and non-liability to shrinkage, although these may be of advantage. The key to the mystery is readily found. Every experienced analyst knows how difficult it is to make a separation of phosphoric acid from calcium by dry reactions, even by fusion with such powerful agents as alkaline carbonates, and how comparatively easy it is to decompose aluminium phosphate by fluxing with alkalies in presence of silica. Hence we may conclude that in the indecomposable nature of calcium phosphate, under circumstances analogous to those of the alkaline separation, lies the potency of phosphate of calcium for the operations of the potter. In other words, this phosphate remains unattached and isolated, and being infusible at the heat of the oven, affords a support to the glassy substances formed by the mutual action of the alkali of the china stone, the lime of the bone ash, and the silica and alumina of the remaining ingredients. The calcium phosphate therefore acts as a backbone, and enables the English potter to employ a high percentage of vitrifying ingredients, and thus obtain the required translucency at a lower temperature than is possible in the manufacture of true china by the Oriental and German methods, and with less distortion and loss in firing. It appeared possible that if aluminium phosphate were mixed with its equivalent of calcium carbonate, together with clay and stone, the result might be formation of calcium phosphate and alumina, in which case a refractory china would be produced. Experiments, however, proved that this is not the case, the trials emerged from the biscuit oven semi-fritted and opaque. The capacity of calcium phosphate, therefore, does not appear to lie so much in its stability of formation at great heats, so to speak, as in its inertness when present from the beginning. With regard to its effect upon transparency, the author suggested that the relations between the indices of refraction of the calcium phosphate and of the glassy materials might not be without influence.

* Abstract of paper read by Thomas Bayley, before the Birmingham Section of the Society of Chemical Industry, on the 7th inst.

CHEMICAL REAGENTS FOR TEXTILE FABRICS.

Various reagents are now in use for the identification of the materials employed for the manufacture of textile fabrics, and recently the processes for the rapid detection of the presence of animal fibres in vegetable tissues and the converse have been much simplified. Animal fibres can be primarily distinguished from those of plant origin by their solubility in strong soda or other alkaline solvent, while the mineral acids char vegetable fibres, and have little or no action upon those derived from animals. Silk and cellulose are soluble in the blue ammoniacal copper solutions, from which the silk is re-precipitated by dilute acids, and the cellulose by several salts. Schlossberger uses a solution of nickel oxide in ammonia for dissolving silk mixed with cotton, in which the latter is insoluble. Nitric acid also dissolves silk, and colours wool and all animal fibres yellow. A mixture of mercuric and mercurous nitrates, for a long time known as Millon's reagent, has also the property of turning fibres of animal origin a red colour. As wool contains a small but constant quantity of sulphur, the blackening of a solution of litharge in a caustic alkali identifies the presence of this substance. Silk, however, is occasionally sulphured, and will then give a similar blackening with this reagent. The amount of silk present in a sample of cloth can be estimated by a method which is based on the fact first observed by Persoz, that it differs from other textile materials in being readily soluble in a hot and strong solution of chloride of zinc. The method of procedure is as follows: The dressing is removed by a preliminary boiling in dilute hydrochloric acid, and after washing the cloth is immersed in a bath of the chloride of zinc solution, which is prepared by dissolving one hundred parts of chloride of zinc, together with four parts of the oxide, in eighty-five of water. The loss of weight after washing and drying gives the quantity of silk present in the material. The amount of wool in the same material can also be determined by taking a fresh quantity, and noticing in a similar manner the loss of weight after it has been heated to 212° F. for a quarter of an hour in a solution of caustic soda of sp. gr. 1·02. Hœhnel has noticed that mulberry and wild silks behave differently when treated with a solution of chromic acid. Wool and mulberry silk dissolve rapidly in this solvent, while wild silk is only slowly acted upon. Boiling hydrochloric acid dissolves silk rapidly, while any wool present in the fabric increases in bulk, but does not dissolve. This method is also used as a means of determining quantitatively the relative amounts of these fibres in a fabric. If a mixture of wool, cotton, pure and wild silk be present, hydrochloric acid dissolves the mulberry silk first, and finally the Jamamai silk, while the wool is dissolved from the unaltered cellulose by means of a solution of caustic soda. Molisch's method for distinguishing between animal and vegetable fibres was recently alluded to in these pages. It is based on the fact that cellulose, when warmed for some time with a mineral acid, yields a small quantity of sugar, which can then be recognised by the addition of a solution of naphthol or thymol in alcohol, mixed with an equal volume of concentrated sulphuric acid. Naphthol under these conditions gives a deep violet colouration, and thymol a vermilion tint, if vegetable fibres were present in the original cloth. Sidoff has also noted that silk is dissolved by fused oxalic acid, while cellulose (cotton) only disappears on prolonged treatment. Wool is not attacked by this reagent. Lastly, the behaviour of various dyestuffs, *e.g.*, magenta, towards the different materials present, often affords a convenient means of identifying the substance used in the manufacture of the fabric.

THE UTILISATION OF TINNED IRON SCRAP.

With the recent increase in the price of tin, the various methods which have been devised for the recovery of the tin used in coating iron in tin plate become of greater interest, and during the last year several new processes have been devised which are likely to be exceedingly remunerative if the present price of the metal can be maintained. All the processes which have been proposed may be divided into two distinct parts, the first consisting in dissolving the tin from the surface of the iron, and the second in conveniently recovering the tin in a metallic state from the solution. In 1886 a method for extracting the tin from tinned sheet metal cuttings by means of hydrochloric acid gas was patented in France and in this country. The patentees, F. Bosshardt, of Manchester, and S. Montague, of Nantes, heat the cuttings in a closed vessel by means of superheated steam to a temperature of 150°C. to 160° C., and then introduce a current of hydrochloric acid gas prepared in an adjacent generator. In this way the tin is converted into its protochloride (stannous chloride), and is finally washed away from the unaltered iron scrap by water, which is pumped into the vessel from above, and distributed by means of a rose jet. The solution of stannous chloride obtained in this manner is then treated with zinc cuttings, which cause the tin to be precipitated in a crystalline metallic form, which can subsequently be melted and cast into bars. The scrap iron remaining in the vessel can also be utilised by being worked up into bars. Their apparatus has recently been modified in such a manner as to make the process a continuous one, and this has enabled the inventors to effect a considerable saving in the amount of hydrochloric acid employed. In this improved form, a series of brick work chambers, lined with asphalt, are packed with the tin plate cuttings, and are arranged so as to permit the hydrochloric gas to circulate from one to the others, and finally the waste gases, which escape into a flue, are found to be almost free from acid. Water spray and steam are employed for removing the chloride from the iron, and the second chamber is then allowed to receive the fresh hydrochloric acid gas, while the empty one is re-filled with a second charge of tin scrap and placed last in the series. The tin is obtained from the liquors by precipitation by means of zinc, iron, or lime. When the latter is employed, a deposit is obtained which is pressed and dried, and finally treated like iron ore. In the specification of a patent taken out some time ago by Mr. Biggs, an arrangement

Digitized by Google

consisting of a revolving metal cylinder lined with asphalt is described, for containing the tin scraps to be treated. Hydrochloric acid of 17°Bé., and at a temperature of about 95°C., is stored in a cistern above this revolving cylinder, and is allowed to slowly fall on the tin scraps. The liquid runs from the cylinder into a tank beneath, and the washings are cooled to allow any lead which may be present to separate. Tubs fitted with revolving beaters have also been proposed by the same inventor in place of the rotating cylinders. E. Edwards, of London, and M. Ramos-Garcia, of Paris, have also patented a method in which the tinned iron is stripped of its coating of tin by immersion in a bath of hydrochloric acid, containing a small quantity of free nitric acid or perchloride of iron (ferric chloride). The solution of the metal is hastened by warming the bath in a current of steam, and the tin is electrolytically recovered from the solution, tin cathodes being employed upon which the metal is precipitated. When tin plate scraps are treated with hydrochloric acid, without any oxidising agent being present, the iron is also dissolved, and a mixture of ferrous and stannous chlorides is obtained in the solution. H. H. Lake, of London, and Worth & Co., of Frankfort-on-the-Main, agitate this liquid with finely divided precipitated chalk or calcium carbonate, which causes the precipitation of the tin as white oxychloride, $SnO\ SnCl_2\ 3H_2O$. This operation is conducted in closed vessels, to prevent the oxidation of the ferrous salt, which otherwise would also be precipitated with the stannous oxychloride. The closed vessel should also be filled with carbonic acid gas, in order to insure the absence of any oxygen. The precipitate of oxychloride is next filtered under pressure, and subsequently boiled with an additional quantity of carbonate of lime, which converts it into pure stannous oxide. These two changes may be represented by the equations:—

$$CaCO_3+3H_2O+2SnCl_2=SnO.\ SnCl_2.\ 3H_2O+CaCl_2+CO_2 \quad (1)$$

$$SnO.\ SnCl_2.\ 3H_2O+CaCo_3=2SnO+3H_2O+CaCl_2+CO_2 \quad (2)$$

The stannous oxide obtained can be converted into the metallic state by reduction with coal, or can be converted into pure stannous chloride by solution in hydrochloric acid. The hydrochloric acid can be recovered from the filtrate of calcium and ferrous chlorides by the addition of sulphuric acid, when calcium sulphate is precipitated, and after being allowed to settle is removed by decantation. The solution on evaporation yields sulphate of iron and hydrochloric acid, which can be utilised in the first operation.

Notes.

MACHINERY IN TURKEY.

The British Consul at Salonica states that steam flour mills are gradually spreading over the country, and that within the last two or three years several have sprung up in the interior—one at Argo-Nicola, another at Kilkitch, and one at Monaster—all being the outcome of native enterprise. The machinery and boilers are mostly of French origin, though in one or two cases they have been obtained from England. The Consul says that no doubt much more machinery of English make would be imported into Turkey if an agent of some manufacturing firm were established there. He also points out that as a rule joiners' work at Salonica is very inferior, and that it should be possible to create a good market for English wood working machinery.

METEOROLOGY.

Mr. Shaw has recently drawn up a report on the various methods employed by meteorologists for determining hygrometric constants. He has examined critically the results obtained by the saturation and chemical methods, and also the values given by the various dew point instruments. Most determinations of the pressure of water vapour in the air are indirect, and require a formula of reduction before an absolute value of the amount can be arrived at. In the formula employed in the chemical hygrometric method, which is provisionally regarded as the standard, it is assumed that Dalton's law is strictly accurate, and that it is possible to absorb all the moisture in the air by dehydrating agents. Sulphuric and phosphoric acid tubes are efficient for this purpose; but it is necessary that two tubes be employed to insure the complete absorption of the water vapour present in the air under examination. Regnault's hygrometer gives very satisfactory and concordant results after some practice; and the instrument perfected by Dines gives very easy determinations of the dew point which are within small limits of experimental error. Alluard's modification of Regnault's hygrometer and Bogen's apparatus also yield satisfactory results.

STEEL WORKS' EXTENSIONS.

Messrs. David Colville & Sons, of the Dalzell Steel Works, Motherwell, have just completed the erection of two additional open hearth steel furnaces, and the necessary gas producing plant. The furnaces are of the ordinary Siemens type, with a capacity of 25 tons each. Other alterations, involving a large outlay, are at present being made at these works, which are now capable of a monthly production of 7000 tons of finished steel. Messrs. Neilson are proceeding rapidly with their new steel works at Clyde Bridge, near Rutherglen, and manufacturing operations will shortly be commenced. The plant has been erected under the superintendence of Mr. Williamson, formerly of the Newton and Blochairn Steel Works. It consists of four fine 25-ton steel furnaces, with cogging and rolling mills for producing the heaviest class of plates and bars, all of a powerful and superior description. The other steel works in the district are all more or less engaged in alterations to enable them to meet the pressure caused by the exceptionally heavy demand for shipbuilding steel.

THE WAINWRIGHT CUPOLA.

On 30th December last we gave an illustrated description of this furnace, which burns natural gas, or producer gas, instead of coke. An experimental cupola on this principle, using natural gas, has recently been tested at Messrs. Price & Co.'s Foundry, at Pittsburg, with very satisfactory results. The bearers for supporting the charge were formed of hollow pipes, covered with fire clay tiles, their temperature being kept sufficiently low by currents of cold air constantly forced through them. A small quantity of coke was placed on the bearers, and on this the pig was charged in 2cwt. lots as fast as it melted, without any further addition of coke. The gas and air were forced into the combustion chamber by a positive rotary blower, and the molten metal was retained till required in the receiver below the charge bearers—its perfect fluidity for any length of time being insured by the intensely hot gas flame playing across its surface. Ordinary cupolas can be readily adapted for melting iron in this manner by the addition of a combustion chamber and charge bearers. Mr. Wainwright is hopeful that his furnace can also be applied to the reduction of iron ores by natural gas, with considerable saving in the cost of both fuel and plant.

WATER SUPPLY FOR 1888.

The rainfall in England during the first two months of the present year has been about 70 per cent. below the average; and unless exceptionally large quantities of moisture fall within the next three months, it seems certain that something approaching a water famine will be experienced during the coming summer. Last year, with a deficiency in the total rainfall of the British Islands of 27 per cent., the scarcity of water was severely felt, both in the country districts and large towns. This year, in the middle of February, Manchester had 2,000,000,000 gallons less water in store than at the same time last year; Liverpool had only 1,015,000,000 gallons in the reservoirs at Rivington, as against 3,700,000,000 gallons in February, 1887; while Sheffield had at that period less than half the usual quantity for the time of year. With the latter town the difficulty is further increased by the fact that dangerous lead poisoning begins to show itself among the inhabitants whenever the supply in the reservoirs falls unusually low. Manchester and Liverpool are presently engaged in gigantic water enterprises, and other towns are doing their utmost to improve their position; but few of these undertakings will be available this year; and as there is little to indicate any alteration in the prevailing meteorological conditions, the most careful husbanding of existing supplies becomes a necessity.

SHEEP SHEARING BY MACHINERY.

That labour difficulties are very often incentives to ingenuity is a fact well known to all who know anything of the history of industry, and it has just received another illustration in Australia. Strikes and the high wages demanded by sheep shearers have led to various attempts to apply machinery to the process of sheep shearing. This was long considered impossible; the first difficulty was to control the animal while being shorn, the second was the construction of the apparatus for shearing it. These difficulties have apparently been overcome by Mr. Woolseley, of New South Wales, and at a public trial a considerable number of sheep farmers and wool brokers from all the Australian Colonies united in the opinion that the machine did the work which its inventors claimed for it. It is very simple in construction, being on the same principle as the cutter of a mowing or reaping machine, and one of its chief advantages is that it does not require a highly skilled person to work it. An ordinary farm labourer can be taught its use in a couple of days, and its advocates claim a saving of fully 10 per cent. At the first public trial fifty or sixty sheep were shorn in a day of ten hours; eighty or ninety is a fair number for a good hand with a pair of shears, but in every sheep shorn by the machine there is said to be a saving of from 4oz. to 12oz. of wool. We fear, however, that except in countries where the cost of labour is high, the machine is not likely to be used to any great extent.

THE LICK OBSERVATORY.

Our American contemporary, *The Iron Age*, states that serious defects in the construction of this observatory will delay the time for fully demonstrating the power of the great telescope. The most serious is the mounting of the telescope on a hollow iron pier 30ft. high, which extra elevation, it is claimed, was not needed on a mountain 4000ft. above the level of the sea. Owing to its extremely great power, the telescope is so sensitive that the placing of a man's hand on the hollow iron pier is sufficient to throw the star entirely out of the field. This can only be obviated by the removal of the present pier, and the building of a solid one of brick or stone, or else placing the base of the instrument directly upon the summit of the mountain. Another serious fault is the removable floor for the great dome. Experience has demonstrated that instead of five it requires fifty minutes to effect the desired change of position of the floor, by which time the object of observation would, necessarily, be in a different place in the heavens.

SWISS RAILWAYS.

The Swiss Federal Council are desirous of gradually acquiring the entire Swiss railway system, and negotiations have been commenced with the North-East Railway Company, with a view to its purchase by the State. The history of this line and particulars of the negotiations form the subject of a Foreign Office report by the British Consul at Zürich, in the course of which he states that the Government consider that, for political and financial reasons, the Swiss railways ought not to be left in the hands of private companies, who in their turn are at the mercy of speculative shareholders, many of whom are foreigners. They are therefore determined to buy up all private railway companies in Switzerland, and to work the lines for the advantage of the Confederation. A majority for the first purchase, that of the North-East, is likely to be found in the Federal Chambers; but the result of the Referendum (popular vote) is at present somewhat doubtful, unless the suspicion can be thoroughly removed that the Government are going to pay too much for the line. During the spring session of 1888 the Federal Chambers will be asked to ratify the contract, which by that time will have been drawn up between the Government and the North-East Company, and the popular vote of the Swiss people will then be taken without delay.

A NEW METHOD OF PREPARING SAFRANINES.

MM. Barbier and Vignon have recently communicated to the French Académie des Sciences a new process for preparing these important dyestuffs. In an article on these colouring matters (*Industries*, Vol. II., page 123), we gave details of the ordinary method for preparing phenosafranine by the oxidation of a mixture of one molecule of paraphenylene diamine and two molecules of aniline according to the equation

$$C_6H_4(NH_2)_2+2C_6H_5NH_2HCl+4O=C_{18}H_{15}N_4Cl+4H_2O+HCl.$$

It is also well known that amidoazobenzene, under the influence of reducing agents, is converted into aniline and paraphenylene diamine, thus:—

$$C_{12}H_{11}N_3+2H_2=C_6H_4(NH_2)_2+C_6H_5NH_2.$$

In the new method, this reaction is allowed to take place in the presence of nitrobenzene, which furnishes the second molecule of aniline necessary for the formation of safranine and also the oxygen required in the subsequent oxidation. The change may be expressed by the following equation:—

$$C_{12}H_{11}N_3+C_6H_5NO_2+HCl+H_2=C_{18}H_{15}N_4Cl+2H_2O.$$

The authors use iron and hydrochloric acid for the reduction, and they find that this reaction takes place at a temperature of about 180°C. The nitrobenzene is added in slight excess, and at the end of the operation any that may be undecomposed is removed by distillation in a current of steam. The reaction takes about three hours for the complete conversion, which is indicated by the change of colour to a deep red. The colouring matter formed is dissolved in water and neutralised with ammonia, and, after filtration, is precipitated from the solution by the addition of salt. The phenosafranine is re-crystallised from hot water, and presents all the characteristics of the substance prepared by the old process. This method has also been applied to the preparation of other members of the safranine series by the substitution of amido-azo-toluol for amido-azo-benzol and other mone-nitrated aromatic hydrocarbons for nitrobenzene.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

24th February, 1888.

2741. Burton, J. D. ..... Calculating machines.
2742. Gay, R., & others..... Lifting and lowering machinery.
2746. Sugden & Binns ..... Boilers.
2756. Matthew, P. M. ..... Manufacture of water proof textile fabrics.
2765. Catlow, C..... Looms.
2767. Wright, S. H. ..... Exhaust pumps.
2774. Lake, H. H. ..... Burnishing machines (*Ross*).
2780. Butler, F. D. ..... Type writing machines.
2783. Tweddell, R. H., and others..... Hydraulic presses.
2788. Sergeant & Cook ..... Mitreing machines.
2804-5. Johnson, J. Y..... Gas engines (*La Société Salomon frères et Tenting*).

25th February, 1888.

2822. Foulds, J..... Propellers for ships.
2829. Sykes, G. W..... Looms.
2834. Jackson & Austin ..... Drilling machines.
2840. Dickie, M..... Looms.
2847. Vaughan, H..... Sheet metal box staple.
2848. Weild, E..... Opening and stretching fabrics.
2849. Hunter, A..... Valve gear for "Corliss" engines.
2850. Stitt, J. C..... Steam engines.
2859. Parr, S..... Warp beams.
2861. Unruh & Liebig..... Grain elevators.
2862. Sedgwick, J. H..... Newspaper printing machinery.
2871. Dutton, R..... Finishing piled fabrics.

27th February, 1888.

2884. Haswell, R..... Hydraulic accumulator.
2892. Hetherington and Hawarth..... Mules.
2895. Curson & Curson ..... Forcing waste steam back to boiler.
2896. Riley, J. ..... Basic hearth steel making furnaces.
2899. Riley, J. ..... Regenerative furnaces for steel making.
2903. Parsons, P. M..... Manufacture of steel.
2905. Black, J. M..... Colour printing.
2910. Lindley, L. ..... Sewing machines.
2912. Knowles & Tatham ... Carding engines.
2913. Oechelhaeuser, W. von Gas engines.
2914. Carver, J. E. ..... Sewing machines.
2915. Hamann, W. C..... Mills for grinding corn.
2916. Lane & Browne ..... Forging and rolling metals.
2922. Johnson, J. Y..... Machines for sewing knitted fabrics (*Quinquarlet, Valton, and fils*).
2928. Bell, T. H., & others... Rock drilling apparatus.
2930. Olsson, P. P..... Knitting machines.
2932. Haddan, H. J. ..... Leather smoothing machines (*Miller & Andreae*).
2936. Harper, J. ..... Screw propellers.
2937. Codling, R. B..... Machines for turning.

28th February, 1888.

2940. James, G. ..... Hydraulic presses (*Hobson*).
2944. Inskeep, J. C. ..... Boiler furnaces.
2950. McGrady, H. ..... Type writers (*Crandall*).
2953. Stokes, G. R. ..... Brake for locomotives.
2957. Lockerbie & Buchanan Brake gearing for railway carriages.
2965. Petrie & Fielden ..... Drying textile material.
2968. Smith & Cooper ..... Manufacture of cords.
2970. Craven, F. ..... Pickers for looms.
2978. Hosking, A. W. ..... Weighing machines.
2986. Higginson, J. ..... Governors.
2996. McNeill, D..... Paper making machines.
2999. Day, C. A. ..... Sewing machines (*Arnold*).
3000. Driggs & Schroeder... Breech loading ordnance.
3007. Fleury, P. A. M. D. O. de Bevelling and grinding glass.
3014. Braun, O..... Centrifugal machines.
3020. Abel, C. D. ..... Gas engines (*Gas Motoren Fabrik Deutz*).
3022. Worrall, T. D. ..... Printing in colours.

29th February, 1888.

3033. Hopkinson, J. ..... Shuttles for weaving.
3038. Bradbury, J. ..... Apparatus for weighing and pressing hay.
3039. Lee, J. F., & others..... Loom shedding motions.
3043. Richardson, C. J. ..... Textile machines.
3044. Hattersley & Hill ... Looms.
3045. Laing, W. R. ..... Spinning, doubling, and twisting frames.
3058. Yates, T. ..... Distributing printers' types.
3059. Koerner, A. C. ..... Breech mechanism of rapid-firing guns.
3069. Stebbing, J..... Rotary engines.
3080. Thornycroft, J. I..... Guns and projectiles.
3082. Fouquemberg, N..... Machinery for agglomerating fuel.
3095. Abel, C. D..... Igniting apparatus for gas engines (*Gas Motoren Fabrik Deutz*).
3098. Davis, C..... Armour plates.
3099. Gastrell, J. P. H. ..... Rotary engines.
3100. Wem, W..... Cartridge ejector mechanism.
3101. Turpin, E..... Breaking up rocks. (Ante-dated 17th February, 1888. Under International Convention.)
3104. Johnson, J. Y..... Winding yarn (*Quinquarlet and Valton*).
3105. Blacklock, J. ..... Circular knitting machines.

1st March, 1888.

3120. Koerner, A. C..... Rapid-firing guns.
3125. Newton, J. ..... Warp lace machines.
3129. Hök, W..... Steam generator.
3130. Whitehead, J..... Spinning of yarns.
3133. Sayer, R. C..... Cable tramways.
3135. Jackson & Martin ..... Type writers.
3138. Widnall, R. L. ..... Fire boxes of locomotives.
3144. Watkinson & Partington..... Brick making machine.
3147. Thompson, W. P..... Mills for grinding or pulverising (*Tixhon-Smal*).
3151. Archer, W. S..... Machines for scutching, carding, or separating fibrous materials.
3153-4. Binns, L. ..... Spinning and twisting frames.
3163. Ber, O. ..... Carriages.
3175. Sallandrouze, T., and others ..... Looms.

ELECTRICITY.

24th February, 1888.

2772. Hedges, K. W..... Electrical safety appliances.
2784. Imray, J. ..... Electrically lighting railway carriages (*Imray*).
2785. Lauckert, E. F. H. H... Electric glow lamps.
2794. McEvoy, C. A. ..... Electrical firing keys.

25th February, 1888.

2808. Joel, H. F..... Electromagnetic conductors.
2819. Nalder, F. H., & others Electrical measuring instruments.

27th February, 1888.

2876. Ward, M. R..... Electrically propelled vehicles.
2933 Haddan, H. J. ..... Regulating dynamos (*Hill*).

29th February, 1888.

3072. Rhoads & Tickhurst... Electric induction apparatus.
3075. Southey, A. W..... Electric arc lamps.
3097. Drake & Gorham ..... Secondary batteries.

1st March, 1888.

3149. Kayser, L. ..... Galvanic batteries.

CHEMISTRY.

24th February, 1888.

2777. Trickett & Noad..... Sodium oxide.
2778. Trickett & Noad..... Extraction of gold, silver, and platinum.

25th February, 1888.

2810. Tennent, R. B..... Distillation of shale.
2816. Williams, W..... Manufacture of salt chemicals.
2831. Parnell & Simpson.... Sulphuretted hydrogen.
2858. Tipping, H..... Oxygen and nitrogen.
2870. Tuthill, E..... Oil from birch tree bark.
2872. Overbeck, Baron de... Aluminium (*Hildwein and Von Schoenberger*).
2873. Overbeck, Baron de... Making alumina from clay (*Hildwein & Von Schoenberger*).
2874. Overbeck, Baron de... Manufacture of alumina from its sulphate (*Hildwein & Von Schoenberger*).

27th February, 1888.

2920. Maxwell-Lyte, F. ..... Basic lead salts.
2921. Caspers, C. J. ..... Impregnating liquids with carbonic acid.

28th February, 1888.

3004. Eckenstein, O..... Actinic light.
3016. Imray, J. ..... Yellow colouring matters (*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, & others*).
3018. Buddicom, H. W. ..... Coating metal with tin.

29th February, 1888.

3094. Merck & Memel..... Hydrargyrum compounds.

1st March, 1888.

3122. Chance, A. M..... Alkali waste.
3124. Chance & Chance ..... Treating vat waste.
3134. Chance & Chance ..... Sulphuretted hydrogen.
3146. Ostermann & Lacroix. Non-magnetic alloy.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Slide Valves.—*W. Donaldson, London.*—This invention relates to a method of opening and closing the port holes by means of a single cylindrical piston valve. The figure represents a sectional plan of the valve and the gear for operating it. In the double motor P¹ is the piston and P the piston rod, which contains the two passages F for the admission of the fluid to move the valve, and two passages G to allow the fluid to escape. The valve V is pierced by two passages Q; the passages I form the inlet ports and E the outlet exhaust ports of the cylinders. The ends of the valve chamber are put in communication with the motive fluid and the exhaust by means of the pipes J and K respectively. When

the passage F is opposite the pipe J the passage G is opposite to K. The fluid then enters the valve chamber and moves the valve, until the passages Q are opposite the inlet port I and the exhaust port E respectively. The fluid is thereby enabled to enter the cylinder through the port I, and moves the piston until the other passage Q comes opposite the other pipe J, in consequence of which the valve is moved in the opposite direction, and the actions of the parts are repeated. The inventor claims the mode of actuating the valve of a double acting motor, the motive cylinder of which is provided with inlet and exhaust ports opened by two ports in the valve by means of the direct admission and exhaust of the motive fluid through ports in the piston rod.—No. 3988. March 16th, 1887. 8d.

Combing Machines.—*J. Pickles, Bingley, and H. W. Whitehead, Leeds.*—Instead of the present construction of the steam chest of Noble's combing machines, the inventors employ a loose metallic steam chest. An additional flange is cast on the ordinary rack circle outside the rack teeth, and at the under side of the plate; a space is thus formed for the insertion of a loose square steam chest or pipe. Cross bars or spring boxes are fixed under the two flanges, and two set screws in them serve to regulate the position of the steam chest. Any required number of pulleys are placed outside the inner flange and underneath the rack circle. Each of the runners is carried on a stud, and regulating screws are provided for pressing the runners against the flange. These improvements are intended for the purpose of obtaining a greater heat to the combs, less friction on the rack circle, and a saving of oil and power. The inventors make one claim.—No. 3665. March 10th, 1887. 6d.

Mowing and Reaping Machines.—*S. B. Bamford, Uttoxeter.*—This invention introduces several improvements into the lifting arrangements and into the draught rod of the machine. On the under side of the double jointed hinge bar, at its lower end nearest to the main shoe, a double ended lever is pivoted, having a long and a short arm. The short arm rests on the bottom of the main shoe, on that side of its hinge nearest to the hinge bar, and the longer arm is jointed at its extreme end to a pin which is passed through a hole in the hinge bar, and is connected to the lifting lever by a chain and shackle. When the lever for lifting the hinge bar is used by the driver of the machine, the chain is tightened and the longer end of the double ended lever is lifted upwards, causing its shorter end to press on the main shoe sufficiently to prevent the outer end of the finger bar from dropping when it is lifted off the ground. The lower end of the draught rod is usually bent in the form of a hook, and connected to the hinge bar. Over the hook the inventor places a shield which slides on the draught rod and answers the double purpose of preventing the lodgment of grass, and of acting as a lock on the hook to prevent its opening out or giving way in case of strain. The inventor makes three claims.—No. 4500. March 26th, 1887. 8d.

Digitized by Google

Boiler Furnaces.—*J. C. Stitt, Liverpool.*—The arrangement of the various parts of the furnace, according to this invention, will be understood by reference to the accompanying diagrams. Fig. 1 represents a sectional elevation of this invention as applied to a marine multitubular boiler, and Fig. 2 is a detailed view of the air supply devices. In Fig. 1, A designates the steam generator, B the furnace, C the combustion chamber, and D the feed water heater. E is an exhaust fan placed in the uptake F, and G are valves by which the gases can be either caused to pass through the feed water heater D, or direct up the funnel. The diaphragm D^1 causes the water to circulate in the feed

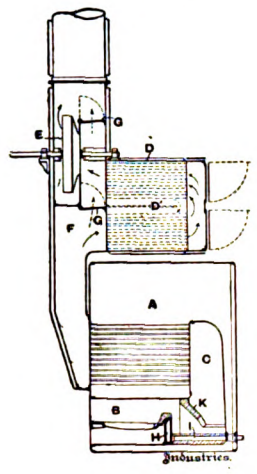

Fig. 1.

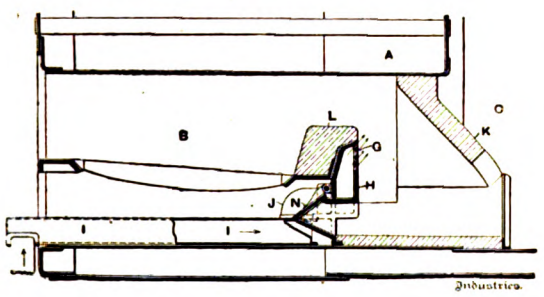
water heater in the opposite direction to the flow of gases in the tubes. The secondary air for burning the gases which have escaped from the furnace is supplied at the bridge from the chest H, and is led thence by the duct I. The arch K is made of fire brick. The details of the latter devices for the secondary air supply are shown in sectional elevation. The air is led from the duct I to the chest by the wing passages J. The door N allows access to the space beyond the bridge L, and the front of the chest H is perforated with a number of holes G, so arranged that jets of air are directed upwards through them. The arch K is disposed in such a manner that the unconsumed gases coming over from the fuel on the grate are supplied with the necessary



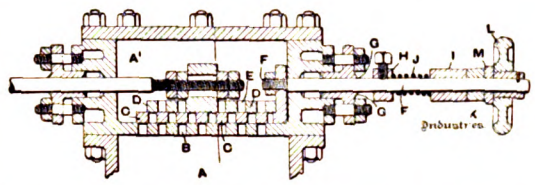


Fig. 2.

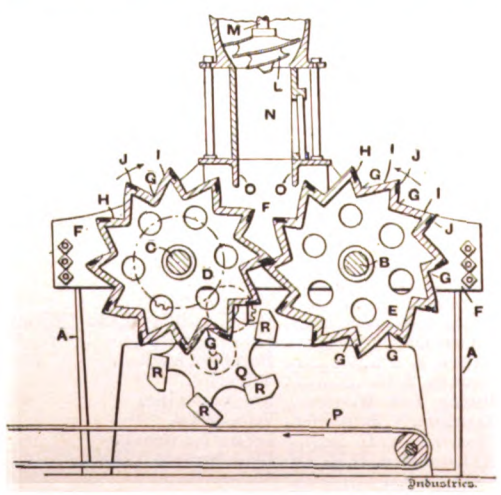
amount of air to consume them in presence of a heated surface of fire brick. The air is supplied to the chest H in measurable quantity by means of a fan. A secondary volume of air is also delivered by the fan E for the purpose of burning the unconsumed gases coming over from the fuel. The different pressures of the air issuing from the two fans are regulated so as to supply the theoretical volume of air. This fact renders it possible to obtain a higher temperature in the furnaces of steam generators than hitherto. In Fig. 2, the air chest is placed behind the bridge, and is shielded from the direct action of the flames. The chest and fire brick arch K are also placed relatively to each other in such a manner that the secondary air mixes with the fire gases when passing over the arch. This method of arrangement is not the only one described in this specification, but several modifications are introduced into the construction of the furnace. The inventor makes five claims for the introduction of the two supplies of the air as described, and for the construction of the parts.—No. 3274. March 3rd, 1887. 11*d.*

Apparatus for Cutting Stone.—*F. Butterfield, Keighley.*—The inventor dispenses with the differential motion described in Patent No. 4752 of 1880, and substitutes a train of reducing gear by which a slow feeding motion of the carrying table is obtained as well as a quick return. The table is arranged on friction rollers, and in order to meet the inequality of the wear and tear on those situated beneath the axes of the revolving cutters, they are mounted on independent carriages so as to permit of their vertical adjustment. In the rotating cutter holders the inventor employs supplementary and interchangeable nuts for insertion in the cutter holders in the event of a set screw breaking, and so obviates a considerable loss of time. The inventor makes three claims for these three improvements. —No. 5164. April 7th, 1887. 8*d.*

Winding and Doubling Machines.—*C. Sipman, Nottingham.* —Instead of placing the guide bar in front of the spindles which carry the bobbins, it is placed over the driving shaft with the guides in a horizontal position, so as to guide the threads on to the bobbins from above. With this arrangement one guide bar will do for both sides in double sided machinery; guides are fixed horizontally on both sides of the guide bar, and one shaft drives the spindles on each side of it. For regulating the tension and holding up the lever of the spindle the inventor makes use of a fork through which the thread runs; and in order to keep the thread in its proper place during its passage from the hank to the bobbin, it is run between two wires which are stretched across the frame. The inventor makes three claims for the arrangement of the traverse bars and guides, for the adjustment of the tension, and for the method of drawing off and guiding the thread, as described.—No. 5668. April 19th, 1887. 8*d.*



Valve Gear.—*A. H. Chartres, Derby.*—This invention relates to the construction and arrangement of an improved variable cut-off gear for steam engines. The accompanying figure represents a horizontal section through the essential parts. A slide valve (not shown) is arranged for admitting steam to the cylinder, and in the steam chest A a number of ports B are formed. The movable port plate C and the valve plate D work in a separate steam chest A^1. The slide valve of the engine is worked from the main shaft, and the valve plate D is similarly worked, but at double the speed. The plate C is worked by the governor, and it is arranged so as to travel intermittently over the ports B in the fixed port plate and the valve plate. This motion is effected by a rod, the collar H, and the spring J. A bevelled surface is formed outside, and is arranged to work with the wedge K, which is connected by a lever with the governor. A wheel L serves to adjust a collar on the step M to or from the wedge K, so as to check its to and fro motion, and so regulates the throw of the movable port plate C. Any

racing in the engine will act on the governor in the usual way, and the motion of the governor is communicated to the movable port plate C. This movement of the plate over the ports will partly or wholly cut off the steam from the main valve chest, and the regulation of the wedge K determines the amount of cut-off and expansion to be allowed. The details of the mechanism for operating the movable plate may be varied by forming a rack on the stem of the plate, gearing with a toothed quadrant actuated by the governor. In this case no check spring will be required. The inventor makes three claims for this cut-off gear.—No. 3681. March 10th, 1887. 8*d.*

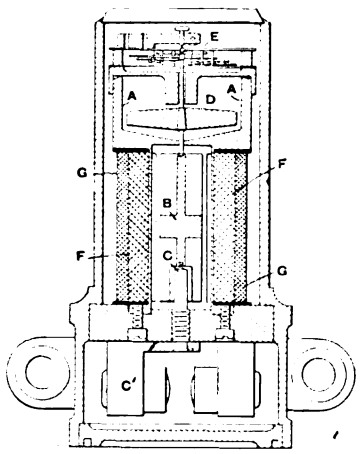
Reeling Mechanism for Rolling Mills.—*F. H. Daniels, Worcester, Massachusetts.*—These improvements are designed with the object of removing the coil from the apparatus and discharging it on to a suitable platform. The reeling takes place round a series of upright fingers fixed in a horizontal plate; and another plate similar to this one is placed loosely on the top, and perforations are made in its surface to allow it to slip over the fingers. Levers are fixed to either side of this movable plate, and are connected to and operated by hydraulic mechanism after the coiling is completed. The movable plate is raised by the levers, and during this position the reel is removed. The inventor makes eleven claims for the details of this construction.—No. 4550. March 26th, 1887. 11*d.*

Brick Machines.—*W. P. Thompson, Liverpool.* (*W. T. Duval and H. Blunt, Washington, U.S.A.*)—The aim of this invention is to simplify the construction of brick machines, and to provide means for delivering the brick without any damage. Two rotary mould wheels are made with complementary cells on their peripheries which help to form the brick. The accompanying figure represents a vertical section of the improved machine. The main frame A sustains the ends of two parallel shafts B and C, which pass through and are secured to the mould wheels D and E. Each mould wheel is formed at its rim into a series of transverse pockets or indentations G. The two wheels are made to overlap each other slightly, and the grooves J are provided for the opposite projections to fit into. The wheels revolve with their ends against the inner faces of the

cheek plates F. As the wheel D revolves, one of its teeth on the inner descending side will overlap the edge of the corresponding teeth on the wheel E, leaving an open space above. The clay will enter this space, and is ready to be compressed into rectangular shape by the revolution of the wheels. The machine is driven by power applied to the shaft C. The feed motion for the clay consists of a revolving screw L attached to the lower end of a shaft M; and the plates O extending downwards prevent an escape of the clay from the top of the wheels. For off-bearing purposes the horizontal belt P is employed; the brick is received from the wheels D and E by the platforms of a revolving wheel Q. The inventors also describe two modifications of the arrangements for delivering the bricks, and make four claims for combination of the two wheels D and E, and for the delivering mechanism.—No. 15906. November 15th, 1887. 8*d.*

ELECTRICITY.

Dynamos.—*S. Z. de Ferranti, London.*—This invention relates to improvements in the dynamos described in the specification of Patent No. 3702 of 1883. The revolving armature is now to be mounted at the end of an axis, which also carries a driving pulley between its two bearings. The fixed magnets on each side of the armature are divided into four sections, two on one side and two on the other, and they are made so as to be easily slidden one away from the other. The armature is made of a number of coils ranged round the circumference of a disc; each coil is made from a strip of metal, which is hollowed in cross section so that the outer coils overlap the inner ones. The overlying coils are thus kept from shifting sideways, and also a much stronger coil is obtained which will retain its original shape during rotation. The ends of the coils which border on the periphery of the disc are received into semi-circular recesses in metallic blocks. Each of these blocks is on one side formed with a finger, which extends outwards from it radially, and lies along the side of the coil between it and the next, serving to carry round the coil with the revolving wheel. Pieces of metal of U shape are employed to prevent the coil flying outwards. Each of these pieces is formed with a plate on either side which extends towards the centre of the wheel, and comes on either side of the blocks resting against the inner bend of the coil. The plates extend inwards beyond the blocks, and a filling piece is inserted between them. A flange is made on the plates at their inner end by which they are fastened to the wheel. The inventor makes six claims.—No. 702. January 15th, 1887. 11*d.*



Dynamos.—*W. P. Thompson, Liverpool.* (*G. Westinghouse, jun., Pittsburg, Pennsylvania.*)—By this invention certain improvements are introduced into the construction of alternating current machines. The bed plate is formed of a single piece of cast iron, of rectangular form, with lateral projections, upon which the bearings of the armature rest. These bearings constitute part of a casting, which comprises the lower half of the field magnet plate for the machine. For the purpose of adjusting the frame upon the bed plate, a chain wheel is mounted on a shaft extending through and bearing in one end of the bed plate. By turning this wheel the position of the machine is easily altered, and the tension in the driving belts is thus adjusted. Half of the core projections are contained by the lower casting, and the remainder by another section, which constitutes the upper portion of the field magnet frame. The cores are preferably made of wrought iron, and are secured in their places by bolts. Their inner ends are constructed with re-entrant curves of a radius approximately the same as the armature, and their edges are turned away from the armature, in order to prevent a bunching of the lines of force. The armature consists of successive plates of thin rolled iron, placed side by side, and separated from each other by thin sheets of paper. Each plate is made with a number of holes for the purposes of ventilation, and the series of holes in the different plates correspond with each other. End plates are employed for the object of forcing the air through these holes in the armature. Thin sheets of mica cover the surface of the armature, in order to insulate the wire. The inventor makes ten claims.—No. 9725. July 12th, 1887. 8*d.*

Electrical Switches.—*C. M. Dorman & R. A. Smith, Manchester.*—This invention relates to that class of electrical switches in which rotary motion is transmitted through the cover of the switch from an external handle. The object is to obtain a good and air tight fit at the point where the actuating mechanism passes through the cover. The porcelain, or other vitreous material usually employed, is not easily made in an accurate shape, and in order to overcome this difficulty the inventors allow the handle to take its bearing in the hole in the cover of the switch, in which position it is constrained by flanges or by a gland. The motion is transmitted to the working parts of the switch by means of a crank pin and slot, or by two crank pins and a drag link, or by any other method whereby the motion may be communicated without undue friction when the axes of the two parts are slightly eccentric. The inventors make one claim for this improvement.—No. 14768. October 31st, 1887. 8*d.*

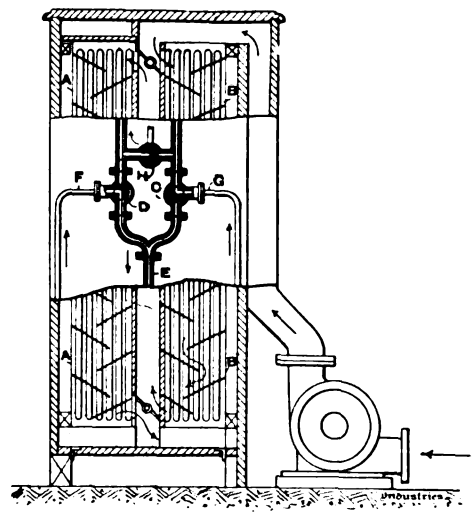
Disc Dynamo.—*H. B. Sayers, London.*—The coils of the armature are wound somewhat after the manner of the Siemens-Alteneck method. The conductors pass round half of the circumference of the disc, instead of crossing the cylindrical surface in a direction parallel to the axis. Also, instead of crossing the two ends of the disc in alternation, the conductor crosses the same end $\frac{1}{2}$ A B times, if A be the number of turns given to each section and B the number of sections into which the coils are divided. The conductor will then pass over to the other end, taking a spiral direction over the cylindrical surface. Segment-shaped spaces are formed by the conductors. These are filled in with thin iron plates varnished on their surfaces, and alternating with insulating material. The divisions between the plates must be parallel with the axis, and are preferably concentric with the periphery of the armature, and somewhat longer than the depth of the radial portion of the conductors measured parallel with the axis. The projecting ends are also made broader than the part which lies against the conductor, so that a nearly continuous surface is formed by the edges of iron and non-conductors; while the conductors are hidden from view except round their periphery. The armature is mounted on the spindle by means of two end plates, one being fixed to the shaft, and the other loose and provided with a nut by means of which it may be forced along the shaft. The poles of the field magnets are four in number, and are arranged so that the magnetic lines of force pass through the disc in a direction parallel with the axis; and their direction through one half is opposite to that in the other half. The armature may run very near to the pole pieces without the danger of heating the latter; and as the polar area may coveniently be made very large, the exciting force required is very small. The inventor makes four claims.—No. 717. January 17th, 1887. 8*d.*

Digitized by Google

ELECTRICAL METERS.—*S. Z. de Ferranti, London.*—This invention relates to that class of meters in which the electrical current to be measured is made to pass through a bath of mercury in a magnetic field, described in Patent No. 5926 of 1883. Pole pieces are employed which do not retain residual magnetism, and the rotation of the mercury during the passage of a feeble current is effected by the use of additional coils of an insulated conductor around the pole pieces of the magnets. These coils form no part of the circuit whose current is to be measured, but is a branch circuit direct from the main conductor to the earth. The accompanying figure illustrates the construction of one of the forms of the meter. The metallic cylinder A is closed at the bottom and filled with mercury, and its inner surface is coated with shellac or

with some other insulating material. The cylinder B is immersed in the mercury, and is formed of a vertical stem of conducting metal with a collar projecting round it at the centre. Insulated coils of thin sheet iron surround the stem above and below the collar. The lower end of the stem rests on a fixed pivot C, which is in connection with one terminal C^1 of the meter. The upper end of the cylinder B carries a weight D to prevent the cylinder floating in the mercury. A train of recording wheels E are actuated by the upper extension of the axis or stem. The coil F of insulated wire surrounding the cylinder A forms part of the circuit of the current to be measured, and G is the additional coil of fine wire through which a branch circuit is conducted from the mains without passing through the mercury bath. The current to be measured enters the meter at the terminal C^1 and passes through the pivot C, then radially outwards through the collar to the cylinder A, and through the coil F to the other terminal. The mercury set in rotation by the passage of the current carries the cylinder B round with it, and the axis of the cylinder conveys the motion to the recording wheels. The inventor makes four claims.—No. 701. January 15th, 1887. 8*d*.

COMBINED ENGINES AND DYNAMOS.—*M. H. P. R, Sankey, Southampton, and P. W. Willans.*—The armature of the dynamo is mounted in the usual way on the overhanging end of the engine crank shaft. The bars of the commutator radiate from the shaft, and the commutator is placed on the end of the armature nearest the engine. The brushes, which press against this commutator, are arranged so that the line of contact crosses the radial divisions of the commutator at a slight angle, and overlaps two divisions with a narrow bearing surface of the brushes. The brushes and their holders are carried on the end bearing of the engine by a circular clip and two pins. The field magnets may be supported by girders or brackets, which extend from the base of the engine past the brush holders of the field magnets so as to protect the commutator. The inventors make two claims for this arrangement of engine and dynamo.—No. 4070. March 17th, 1887. 11*d*.

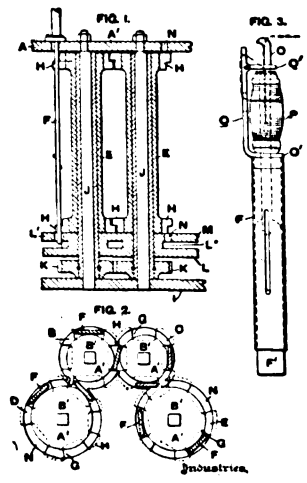


ELECTRIC BATTERIES.—*C. L. R. E. Menges, The Hague.*—This invention relates to that class of primary and secondary batteries in which the electrodes are formed with a core to assist in the generation of electricity, and to serve as a support for the active material. In the ordinary trellis work electrode, the transverse section of the bars which intersect one another has the form of an elongated rectangle. The improved electrode is constructed so that the parts which intersect have the form in transverse section of channels or gutters, so that the active material cannot leave its support either in a downward or lateral direction, even if the mass should no longer possess any cohesion at the centre of the plate. The sides of the channels meet at a right angle, and the area of the surface of the electrode is thus 1·41 times larger than that of an ordinary trellis work electrode of the same thickness. The electrode can be cast in a single piece by means of a special arrangement of the mould. The mould is so constructed that on opening it one half shall be compelled to move in the direction of the line of intersection of the sides of the channels, and thus moulds of sand or of metal may be used. The plate may be removed by pulling at the lower edge, whereby the whole plate is lifted, because the inclined sides of the channels act like wedges. The two parts of the mould are not adjusted one upon the other by means of bolts, but by means of triangular pieces which are fastened to one of the side parts, and which engage with the V shaped pieces secured to the other part. The upper part of the mould can then be moved along the sides of the triangular pieces in either direction. When this movement is effected in one direction, the cast plate will remain in the lower part of the mould. By replacing the upper part and effecting the movement in the other direction, the plate will be detached from the lower part and will remain in the upper part of the mould. However, as the plate had already been removed from this part of the mould, it adheres but slightly to it, and consequently its removal is easy. The inventor makes two claims.—No. 11923. February 19th, 1887. 8*d*.

CHEMISTRY.

TREATMENT OF COPPER PYRITES.—*J. Hargreaves, T. Robinson, and J. Hargreaves, Widnes.*—The copper, silver, gold, and sulphur contained in cupreous pyrites are separated from the oxide of iron by first rendering them soluble in a series of converting chambers, described in Patent No. 5681 of 1886. Each chamber is provided with earthenware grids, or perforated supports, to carry the pyrites. A tall vertical kiln is fitted with special apparatus for inducting hot gases, and causing them to permeate the pyrites. The gases enter the kiln under a lining hood, placed near the bottom, and apertures in the hood distribute the gases amongst the charge. To obtain an increased quantity of sulphur and sulphuric acid, hot air is admitted to the pyrites burners, mixed with heated sulphurous acid gas. Three separate interchangeable burners are employed. After the burning is completed, the oxidised pyrites is rendered soluble by moistening it when cold with strong solutions of chloride or sulphate of iron, or liquid hydrochloric or sulphuric acid, and heating the mixture in the closed chambers by passing hot gases through them. The resulting sulphate or chloride of copper is in a marketable state, and the gold and silver is precipitated by means of iodides. The inventors make twelve claims for this improved process.—No. 3704. March 11th, 1887. 8*d*.

MISCELLANEOUS.



REFRIGERATING APPARATUS.—*J. Imray, London. (La Compagnie Générale pour la production du froid, Paris.)*—In the specification of Patent No. 2387 of 1885 an apparatus is described for cooling air by means of the alternate vaporisation and condensation of a volatile liquid, such as ammonia. Two sets of coils were used, one of them for cooling the air and the other for compressing the gas into liquid form. The heat given off in the latter coil was utilised for melting the rime deposited on the refrigerating coil. The present invention introduces improvements in the construction of this apparatus. A third set of coils is combined with the other two so as to operate in the following manner: At every alternation of the two coils there exists in the refrigerating coil a volume of gas which has nearly attained to the temperature of the air supplied. This volume is made to pass through the other coil, where its heat serves to melt off the rime. Again, while the refrigerating fluid is kept constantly circulating through the third coil, the air which has been

cooled below the freezing point by the other coils, and has deposited its moisture, is passed over the third coil. This air, being almost absolutely dry, deposits no rime, and consequently becomes cooled to a very low temperature. If, after a time, a little rime is found on the third coil, it is only necessary to pass the warm air over it. The accompanying figure shows a vertical section of the apparatus. Supposing the coil A to have had the rime removed from it, and that the coil B is covered with rime, the vapour is distributed by the cock H through A, and will drive out the vapour therein contained which has become warm, while the rime has been melted off the coil. The warm vapour passes through G C into B, the rime of which has been melted. The pump then draws it through F, D, and E. The cock C is turned one quarter round, causing the cold vapour in A to pass directly to the pipe E, which leads it to the compressor; the cock D is also turned round one quarter, so as to inclose the vapour contained in B. The rime having been entirely removed from the latter, the position of the cocks is reversed, and the actions are repeated. The refrigerating vapour is caused to circulate through the tubes A B alternately. The dried air, after having been cooled in these coils, is made to pass to the third coil, through which the refrigerating vapour circulates continuously. The air in contact with these surfaces will be readily reduced to a low temperature. Three claims are made for this improved process.—No. 3793. March 12th, 1887. 8*d*.

SPINNING MACHINERY.—*P. Eadie, Paisley; R. Eadie, Manchester; and J. Eadie, Paisley.*—This invention relates to the rings and travellers employed in ring spinning and ring doubling machines. The ring is provided with a vertical tubular portion, and also with a flange by which it is supported upon the ring rail. A circular opening is made in the ring rail in order to receive the flange, and the ring is prevented from passing through the ring rail by means of a projecting part formed either on the flange or on the ring rail. The traveller is formed of a straight or nearly straight part of greater length than the tubular part of the ring; the ends of the straight part are folded back over the ends of the tubular part. In some cases the upper extremity of the traveller is bent towards the straight part. The lower end of the traveller is prevented from moving beyond a certain distance outwards from the spindle by means of a projecting ring formed upon the under side of the flange. A groove is made in the upper end of the tubular part of the ring to allow the thread to pass from the traveller to the spindle. In order to lubricate these parts, a right or left handed screw thread is formed in the tubular part for the retention and distribution of the oil. A hole in the ring allows the passage of the oil to these threads, and as the traveller passes over the screw thread it becomes lubricated. Instead of the screw threads the tubular part of the ring may be grooved horizontally for the same purpose. The inventors make four claims.—No. 4880. April 1st, 1887. 8*d*.

BRAID MACHINES.—*J. Lami, Paris.*—The present improvements are introduced into the construction of braid machines, in order to enable them to be worked at a greater speed. The accompanying figures show how this invention is carried out. Fig. 1 represents a vertical portion of the machine, including two of the carriers for impelling the racers or bobbin holders; Fig. 2 is a plain view showing the race circles in the upper platform; and Fig. 3 is an elevation of one of the racers and its bobbin. The machine is constructed with four platforms A L M I. In the platforms A and M are cut the race circles N, in which the racers travel. Each racer is formed of a flat tube F fixed to plate O^1, and provided with a flat weighted spindle F^1. This spindle works in the tube F, and its movement is limited by a pin fixed to it, and working in a slot in the tube. The

upper end of the spindle is also flat, and is provided with an eye through which the thread passes. A hole is made in the top of a round tube O, and the thread also passes through the opening before it leaves the racer. The tube O is fixed to a vertical extension Q of O^1. A hole in the projection Q^1 is made for the passage of the thread previous to its entry into the eye in the spindle F^1; and a forked pawl attached to Q^1 engages with the teeth on the upper end of the bobbin P. The portions of the platform which are isolated by the race circles are connected to the frames by the central pins J. The racers are caused to travel through the complete circuit by means of the carriers B C D E, in whose recesses G the racers work. The fixed pins J are supported in the base I, and the cylindrical bosses L^2 connect the platforms A and M together. By this apparatus the carriers impel the racers through the whole circuit of the race circles, and the threads are held in tension and the racers in equilibrium by means of the weighted spindles. The inventor claims: (1) The construction of the spindle and bobbin as shown in Fig. 3; (2) the construction of the race carriers as shown in Figs. 1 and 2; and (3) the improved apparatus as described.—No. 16492. November 30th, 1887. 6*d*.

VULCANISED METAL OBJECTS.—*J. Bosch & W. Kumpfmiller, Munich.*—The object of this invention is to obtain sheets and jars combining the rigidity of metal with the resistance of vulcanite to acids. The receptacles are formed from perforated sheets of metal, or from wire gauze, and on both sides of this frame work are placed sheets of vulcanised rubber. These parts are then subjected to pressure; the rubber is thereby connected over all parts of the sheets through the perforations, and the two layers of rubber are joined together as one block. In performing this process, the metal vessel to be vulcanised is treated with chloroform before applying the plates of rubber. By this invention, great strength is imparted to an uncorrodible vessel, and the two coats of rubber are made immovable by their being joined together through the perforations in the metal skeleton. Two claims are made.—No 17467. December 19th, 1887. 6*d*.

PAPER CUTTING MACHINES.—*H. J. Salmon, J. Capper, and W. H. Duffett.*—In paper machines as ordinarily constructed the gauge at the back is moved to and fro by a hand screw. In order to overcome the disadvantages incident on this method, the inventors gear the screw shaft of the gauge with a pulley which is constantly rotated by the motive power of the machine. Apparatus is supplied for easily throwing this shaft in and out of gear. Arrangements are also made for showing the distance of the face of the back gauge from the cutting knife. For this purpose an endless band of thin steel is placed round two pulleys, and one side of the band is connected with the gauge so as to move to and fro with it. The face of the band is marked in inches and fractions, and there is a pointer at the front of the machine for indicating its motions. The paper is kept against the face of the gauge when it is moving back from the knife as well as when it is moving towards it, by means of two or more endless bands, which pass over two pulleys at the back of the machine and on the table near the knife respectively. The paper to be cut is placed over these endless bands which keep it close against the gauge. In some cases the bands may have motion imparted to them for the purpose of feeding the paper

Digitized by Google

against the gauge. The inventors claim the method of driving the gauge screw, the arrangement of the steel ribbon for the purpose described, and the combination of the tapes for propelling the paper against the gauge, and the bands for keeping the paper against the face of the gauge when it is moving from the knife.—No. 4825. March 31st, 1887. 11*d*.

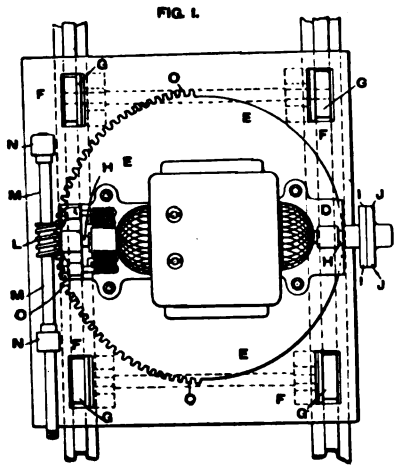
Covers of Rotating Shafts.—*W. Taylor, Oldham.* (*F. Lejeune, Vienna.*)—This invention relates to a locking device for the covers or guards of rotating shafts, and consists essentially of a stud on the cover, in combination with a hook operated automatically by the rotation of the shaft. A collar is formed on the shaft, and has a projecting portion with an inclined surface. On the bearing of the shaft a boss is fitted loosely, and is prevented from rotating with the shaft by a stud. In the boss is a recess with an inclined surface corresponding to the inclined surface of the collar. A hook on the boss engages with a stud which is fixed on the cover. When the shaft is being rotated the cover is locked by the hook and the stud, and cannot therefore be turned back or removed. When the shaft is stopped, when the inclines agree with each other, the recess in the collar allows the boss to move close to it, thereby disengaging the hook and releasing the guard. Immediately the shaft resumes its revolution the incline in the collar throws the boss back and brings the hook over the stud, thus automatically locking the cover. The inventor makes two claims.—No. 17239. December 15th, 1887. 6d.

Spindles.—*W. Sumner, Almelo, Holland.*—In order to prevent the wearing at the external bearing of the spindle and at the internal part of collar bearing, the inventor introduces a special construction of both bolster and spindle. The spindle is reduced at its bearing part or at the traverse part of its bearing, and a bush of phosphor bronze or other metal is applied to the inside of the old collar bearing. The bush also fills a portion of the hole of the bobbin, and its inside fits freely but firmly in the reduced bearing part of the spindle. A countersink is formed in the upper collar as a reservoir for a lubricant, and a hole at the side allows the oil to pass to the spindles. The inventor makes three claims.—No. 11327. August 19th, 1887. 8*d*.

Utilisation of Furnace Slag.—*G. J. Snelus, Workington.*—The slag from the Siemens-Martin steel furnaces is allowed to run in a thin layer upon a cast iron plate, so that it can be easily broken up into pieces when cold. The broken pieces are then either used over again in the blast furnace or are used for road metal. The inventor makes one claim for this method of treating the slag.—No. 4389. March 23rd, 1887. 6*d*.

Apparatus for Cutting Coal.—*T. Bower, R. W. Bower, and J. Blackburn, Woodlesford, Yorkshire.*—The object of this invention is to improve the construction of the cutters, and also to simplify the means employed for its operation. The cutter bars are made of such a form that they can more readily be withdrawn from the work. A section of the improved form is shown in Fig. 2. The cutter bar A is made of taper form towards its outer extremity, and the cutters B are gradually reduced in size. The base of the cutters B may be of polygonal form, and diamond-pointed steel bits C are screwed into them. When electricity has been used for driving these bars, the motor has usually been constructed separate and distinct from the

FIG. 1.



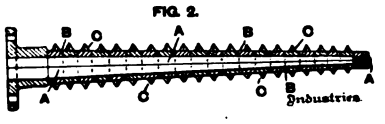


FIG. 2.

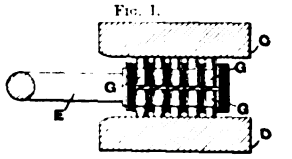
machine. According to this invention the motor is coupled directly to the machine as illustrated in plan in Fig. 1. An Immisch motor D is mounted on a turntable E carried on a bed plate F. The wheels G support the whole frame work. The motor shaft H has a coupling plate I at its end, corresponding with another plate J on the cutter bar A. The rotary motion is imparted to the turntable by means of a worm L mounted on a shaft M, and the gearing O on the rim of the table E. Any other motor may be applied for this purpose beside the Immisch. The inventors make two claims: (1) For the form of the cutter bar; (2) for the disposition of the motor and the gearing for the operation of the machine.—No. 16955. December 9th, 1887. 6*d*.

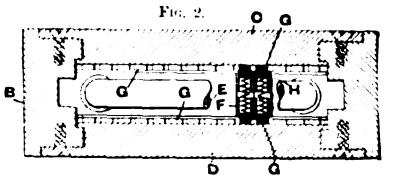
Vulcanisation of Waterproof Fabrics.—*H. H. Waddington.*—The fabric to be vulcanised is passed continuously through a chamber of such dimensions and so arranged and heated that the vulcanisation is completed during its passage from one end to the other. Inside the chamber are arranged a number of rollers in two series, over and under which the fabric passes. A certain number of these rollers are driven by gearing, and some of them are made hollow for the reception of steam. Several of the rollers near the outlet are cooled by a current of cold water, in order to give a finish to the india-rubber. The inventor makes two claims for the method and for the apparatus. —No. 15680. November 16th, 1887. 8*d*.

GERMAN PATENT ABSTRACTS.

Electrical Switches.—*W. Fritsche, Berlin.*—The inventor has designed this switch for the transmission of strong electric currents. The difficulties met with in constructing these apparatus are that the surfaces in contact must be very large, and it is consequently difficult to manufacture them in such a manner as to insure contact all over the surface. Moreover, even if a perfect contact be made when the switch is new, the surfaces soon begin to wear, so that after a short time the contact becomes imperfect. The inventor has overcome these difficulties

Fig. 1.





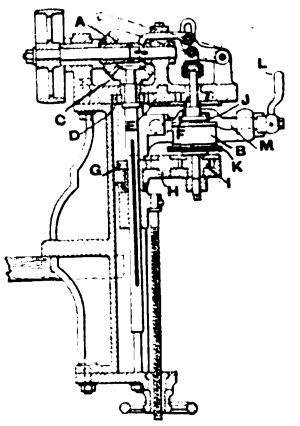


Fig. 2.

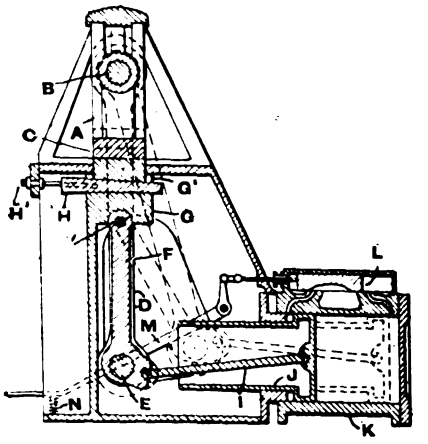
by dividing the transmitting area into a number of small surfaces which are easily made with sufficient accuracy. The terminals to which the wires are connected consist of two metal plates C and D, separated by insulating pieces A and B. The connection between C and D is effected by inserting the piece S. The body of S carries a number of perforations into which hollow pieces of metal G fit, which are pressed into contact with C and D by the coiled springs H, shown in Fig. 2. The air circulating through the spaces between G materially assists in keeping the switch cool.—No. 42143. May 13th, 1887.

Closing the Lids of Tins.—*A. Reiche, Dresden.*—The arm A carries a roller which folds the extremity of the cylindrical part of the tin over the loose end cover. The tin B is held between

two discs J and K, which are rotated by the bevel wheels A and C, and the spur wheels D, E, F, G, H, and I. By means of the lever L, the roller is pressed against the tin.—No. 41893. December 28th, 1886.

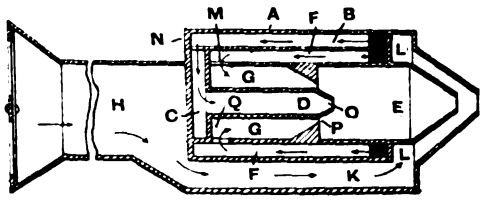
UNITED STATES PATENT ABSTRACTS.



Cushioning Device for Pistons.—*E. F. Smith, Brooklyn.*—A supplementary steam pipe is introduced through the lower circular end of the upright cylinder, and communicates directly to the interior space in the cylinder. At a short distance below the cylinder, the steam pipe enlarges into a steam box, in which is enclosed a swinging check valve. Below this valve is another which is operated by a crank connected by a link to a trip lever. The trip lever is pivoted to the slide block on the piston rod. The latter valve is operated intermittently by the moving parts of the machine, so as to be open as the piston ascends through its upward stroke. Towards the close of the downward stroke the valve is closed, the swinging check valve falls against its seat, and the imprisoned steam acts as a cushion for the descending piston. This supply steam plays no part in the actuation of the machine, but only serves the subsidiary purpose of cushioning. The inventor makes four claims.—No. 377840, dated 14th February, 1888.

Treating Fibrous Ware.—*H. Carmichael, Malden, Massachusetts.*—The fibrous ware is first thoroughly dried and then raised to a considerable heat. In this state it is placed in an earthenware vessel, into which is forced a mixture of asphalt and colophony, or the dark coloured resin obtained from turpentine. The proportions of the mixture are one part of asphalt to five of colophony. During the process all air is exhausted from the vessel, and the mixture is thus forced in by the outside pressure.—No. 377928, dated 14th February, 1888.

Electrolyte Compound.—*G. B. Pennock, Brooklyn.*—In order to prevent evaporation and crystallisation in an electric battery, the inventor makes use of a certain depolarising jellied compound as an electrolyte. This compound is formed by the addition of mineral wool to such acids as sulphuric and chromic in an aqueous solution. The porous cup of the battery with the electrodes contained in it are placed in this compound. The inventor makes four claims for the method of manufacture and application of this new electrolyte.—No. 377210, dated 31st January, 1888.

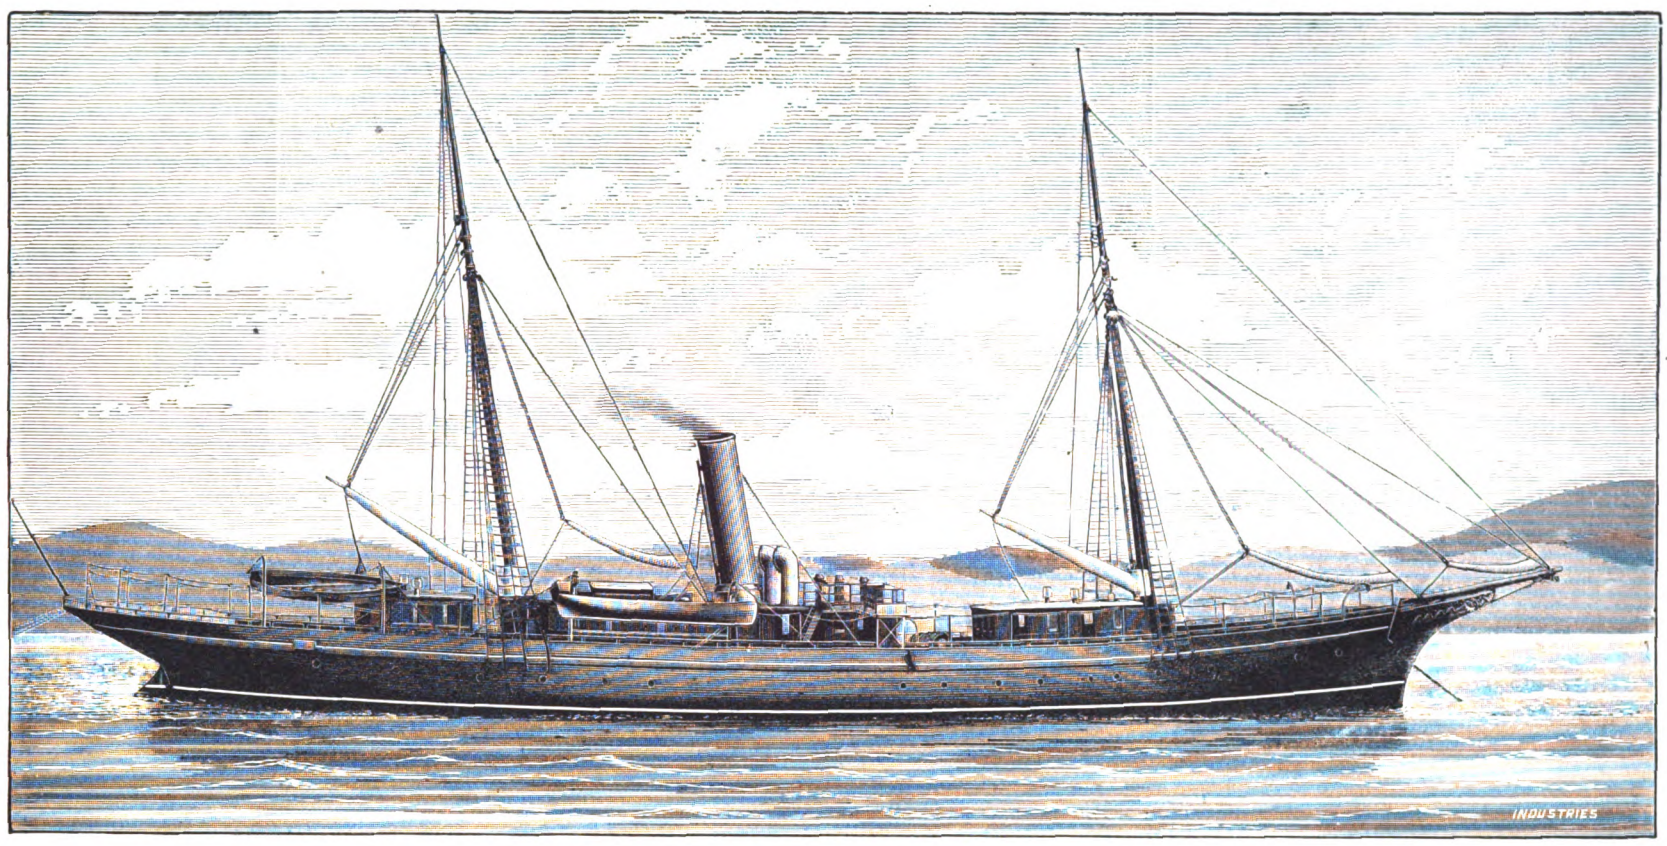


Copper Ores.—*T. Kiddie, New Brighton, New York.*—This invention relates to an improved process for separating the impurities and precious metals from copper ores. After desulphurisation and calcination the resulting mass is dissolved in a sufficient quantity of sulphuric acid to produce a neutral solution. Hydrated oxides of alkali metals or iron are then added with or without heat and agitation; the impurities are thereby precipitated, and they settle to the bottom with the precious metals and other insoluble matter. The sulphate of iron and copper which are produced by this process are afterwards treated in the usual way. The inventor makes two claims.—No. 377809, dated 13th February, 1888.

Hydraulic or Steam Press.—*J. F. Allen, New York.*—In the accompanying diagram two positions of the improved mechanism are shown. The motor cylinder K is fitted with a trunk piston J. The piston rod I is connected to the strut F, which is pivoted at its fixed end to the lower platen G. The other end of F is pivoted by means of the shaft E to the rod D, and the upper end of D is connected by the shaft B to the top of the movable platen C. The movable platen C is constructed with grooves in its sides, so that it may reciprocate vertically in the slotted bearings A, while the lower platen G¹ is supplied with a mechanism for

raising and lowering its seat according to the work which is being performed. This mechanism consists of a wedge plate H, which is inserted between the two parts of the platen G and G¹, and the lower surface of G¹ is also cut to the same angle with the horizontal as the angle of the wedge. The screw H¹ serves to adjust the wedge between G and G¹, and thus regulates the height of the platen. The valve for admission and exhaust of the motive fluid is shown at L, and its movements are controlled by the hand lever M. The inventor makes four claims for the details of this press, and for the combination of the platens with the rods connecting them with the source of power.—No. 377132, dated 31st January, 1888.

Hydrocarbon Oil Burner.—*G. K. Cummings, New York.*—The invention here illustrated is a device for successively vapourising the oil and mixing it with steam and previously heated air. The steam, which is used for heating and evaporating the oil, is introduced into the superheating chamber F, and it then pursues the course indicated by the arrows. While in the chambers F and G it heats the surrounding chambers B and K. The oil enters the chamber B, and becomes partly volatilised there, and the vaporisation is completed in the reservoir C and in the nozzle D. The air which is required for combustion is admitted to the space K, where it is heated by contact with the



wall of the steam chamber F. The steam issues through the nozzle P, and draws out the vaporised oil into the mixing chamber E. The mixture then passes out through the nozzle of the mixing chamber E, where the heated air and the gaseous fuel mix. They afterwards pass out through the nozzle in the outer casing A, and burn in the usual way. The air and oil being thoroughly heated, furnish a powerful flame. The inventor makes eight claims for this burner.—No. 377146, dated 31st January, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE STEAM YACHT "THETIS."

(For description see page 261.)

GENERAL VIEW.

THE EFFICIENCY OF STEAM SHIPS FROM THE OWNERS' POINT OF VIEW.

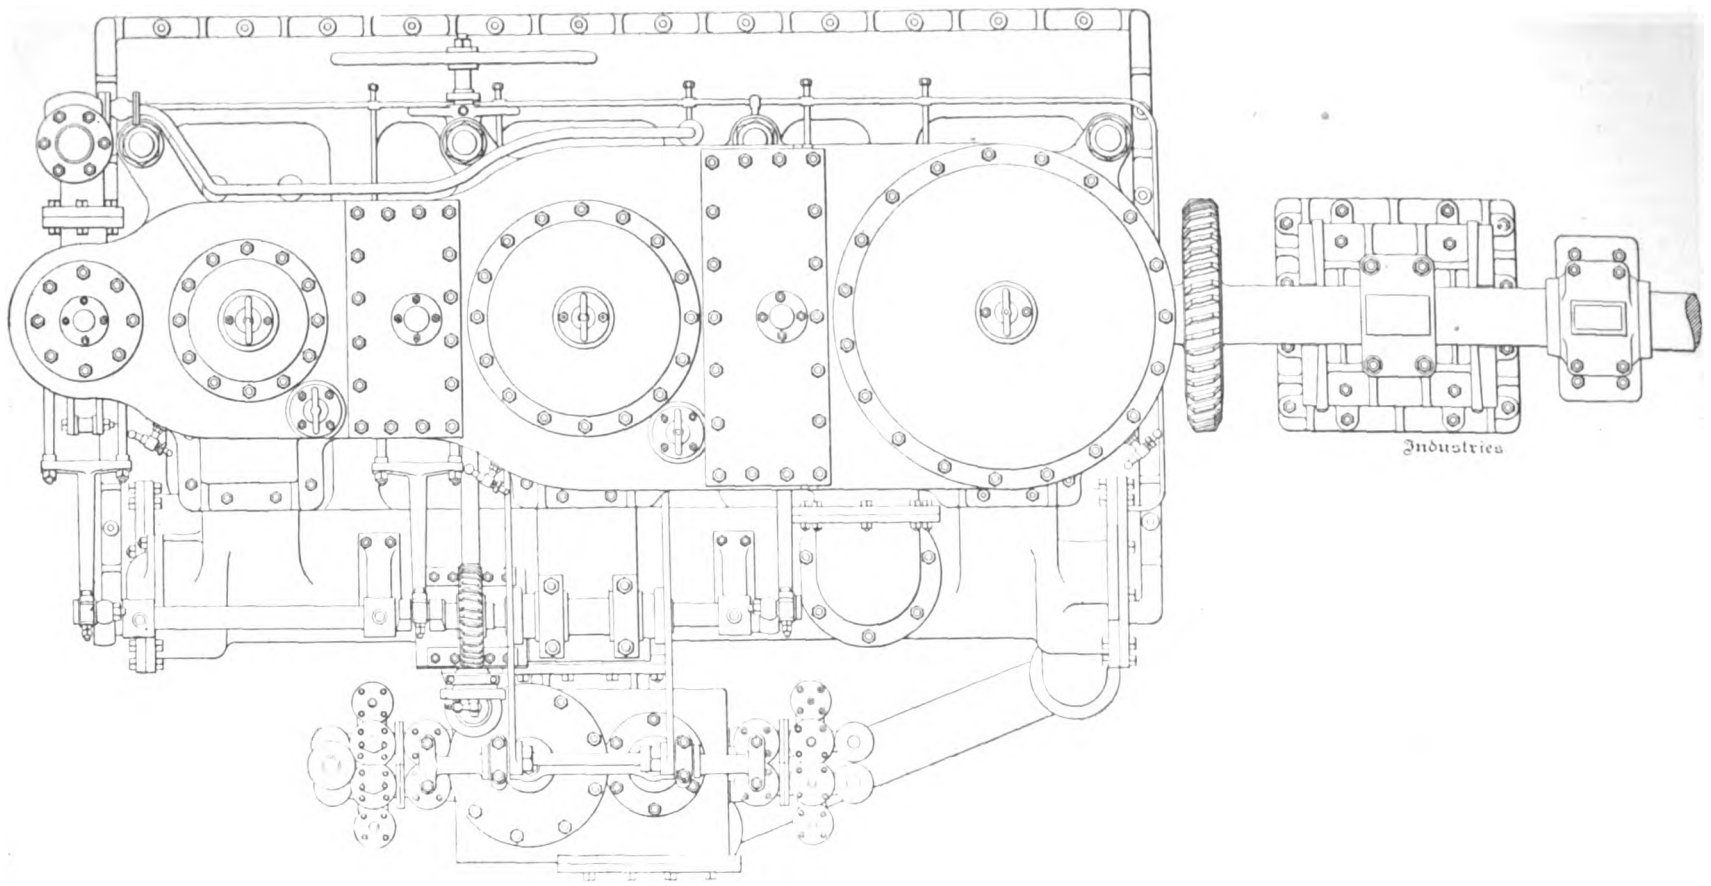
THE concluding lecture of the course, which has been delivered during the winter months under the auspices of the Clyde Steam and Sailing Ship Owners' Association, was given last Monday evening, by Mr. Henry Dyer, C.E., M.A., vice-president of the Institution of Engineers and Ship Builders, Scotland, the subject being "The Efficiency of Steam Ships from the Owners' Point of View."

After some introductory matter indicating the general extent of the subject, Mr. Dyer proceeded to consider the items which affect the resultant efficiency, and to which the ship owner ought to direct his attention. These items may be arranged in three groups: (1) Those relating to the hull of the vessel; (2) those relating to the engines and propellers; (3) those relating to the equipment, the officers and men, and the ship owner himself. It was mentioned that the design of the hull of a vessel ought to be studied from at least three points of view: (*a*) As to its shape; (*b*) as to its strength and weight; (*c*) as to its method of construction. The shape of the vessel affects both its stability and the resistance it offers to propulsion through the water, both of which were briefly considered. It was stated that many of the huge merchant steamers are built with the least possible margin of stability, and that very often that is reduced by "careless or ignorant method of loading." With regard to the influence of the shape on the resistance to propulsion, more attention to that subject was urged, as some ship builders and ship owners seemed to think that anything in the shape of a ship which could be made to float can be propelled at low speeds at economical rates. They pay considerable attention to the engines, and do all they can to obtain a saving of an additional quarter of a pound of fuel per i.h.p; but they seem to forget that the shape of the hull is a very important factor in the consumption of fuel, and that it is possible for an old fashioned ship with a well formed hull, although its engines are wasteful, to be to them a more economical ship than one whose hull is badly shaped, even although it has engines of the most improved design. It was pointed out that from a commercial point of view, if a steamer is to be adapted to easy propulsion, it must have a sharp form, and that within reasonable limits; nothing is gained by the box form, but that much is lost, and further, that the same weight or quantity of cargo may be carried with much less expense in a moderately fine ship than in one of the box type. The subject of the strength and weight of the hulls of vessels was then discussed, and its bearing on their commercial efficiency considered, and the necessity for some modifications of Lloyd's rules was urged.

Coming to the consideration of the efficiency of the engines and propellers, it was pointed out that this may be divided into three components: (1) The efficiency of the boilers; (2) the efficiency of the engines, (*a*) as heat engines, (*b*) as machines, (*c*) as regards their weight and the space they occupy; (3) the efficiency of the propellers. But stoking was mentioned as one of the chief causes of the loss of efficiency of boilers, and it was shown that this may neutralise even the best design and construction. Regarding forced draught, it was urged that a series of trustworthy public trials be made with the object of supplying some definite information on a subject concerning which very little is practically known, and about which a very wide difference of opinion exists. The advantages of the use of liquid fuel were referred to, as well as some of the dangers and difficulties attending it. A somewhat detailed description of the development of the marine engine was then given, and the various points affecting the efficiency indicated, including the use of high pressure steam, the simple, compound, triple, and quadruple expansion engine, and the functions of the steam jacket. The state of our knowledge regarding the efficiency of the mechanism of marine engines was touched upon, and the necessity for definite experiments urged, as the modern marine engine is at present in such a stage that the comparison of ordinary compound with triple or quadruple expansion engines, in the manner in which it is usually done, is very apt to lead to wrong conclusions.

The following figures were quoted to give some idea of the economy of fuel caused by successive improvements of the steam engine. In Smeaton's early engines on the Newcomen principle the consumption of coal per i.h.p. per hour was nearly 30lb.; in his later ones 18lb. Cornish engines are reported to have had a consumption of nearly 11lb. in the year 1811; 1·73lb. in 1842; and 2·90lb. in 1872; while Watt is said to have begun with 8·3lb. and ended with 2·7lb. These figures of course all apply to land engines. In 1863 the average consumption of coal in the best marine engines was 4½lb. per i.h.p. per hour; in 1872 it had been reduced to about 2¼lb.; and now with triple and quadruple expansion engines it is as low as 1½lb. or 1¼lb. It was stated that the triple expansion engine has saved the ship owner about 25 per cent. of coal consumption, allowance being made for the smaller space occupied by the machinery and coals.

The weight of the engines and boilers on board a ship (and consequently the space they occupy) has a considerable effect on its commercial efficiency, or profits it yields to its owners; for if economy of fuel be obtained by a sacrifice of space, or by great additional weight, the commercial efficiency of the ship may be considerably reduced. Every ton of deadweight capacity is worth on an average £10 per annum for earning freight; that is to say, that every one hundered tons saved from the weight of the engines and boilers, without increasing the cost of working, is equivalent to £1,000 a year additional income to the owners. The weight of machinery, including engines, boilers, water, and all fittings ready for sea of ordinary merchant steamers is about 480lb. per i.h.p. In some cases this has been reduced to about 390lb., and Mr. Marshall, of Newcastle, recently stated that he was of opinion that it might be reduced to 250lb., and he undertook to construct engines under ordinary commercial conditions which should not exceed this. The lecturer thought, however, that few engineers or ship owners would in the meantime be inclined to go so far as this, but still the subject is one deserving more attention than it usually receives.



The subject of the propulsion of ships, of trial trips, and progressive trials, and the lessons to be deduced from them was then considered, but our space will not allow us to enter on them. It ought to be remembered, however, that in testing the economical performance of ships, too much dependence should not be put in the results of short trial trips. These, however honestly conducted and reported, are generally carried out under conditions which it is impossible to obtain under long voyages; and in any case the data derived from trial trips should be supplemented by the results of observations made during these voyages.

Coming to the last division of his subject, Mr. Dyer considered the efficiency of the equipment and management of ships under the following heads: (1) The efficiency of the mechanical appliances for working them; (2) the efficiency of the officers and men; (3) the efficiency of the ship owners. In 1854 there were 4·36 persons employed per 100 tons, while in 1885 the number had been reduced to 2·76 persons, and further, the number of persons now required to work a steam vessel is about one half of what it was at the beginning of Her Majesty's reign; a fact which proves how necessary it is for the ship owner keeping himself informed regarding the most recent developments of mechanical engineering. The increasing complicated duties of the ship owners, officers,

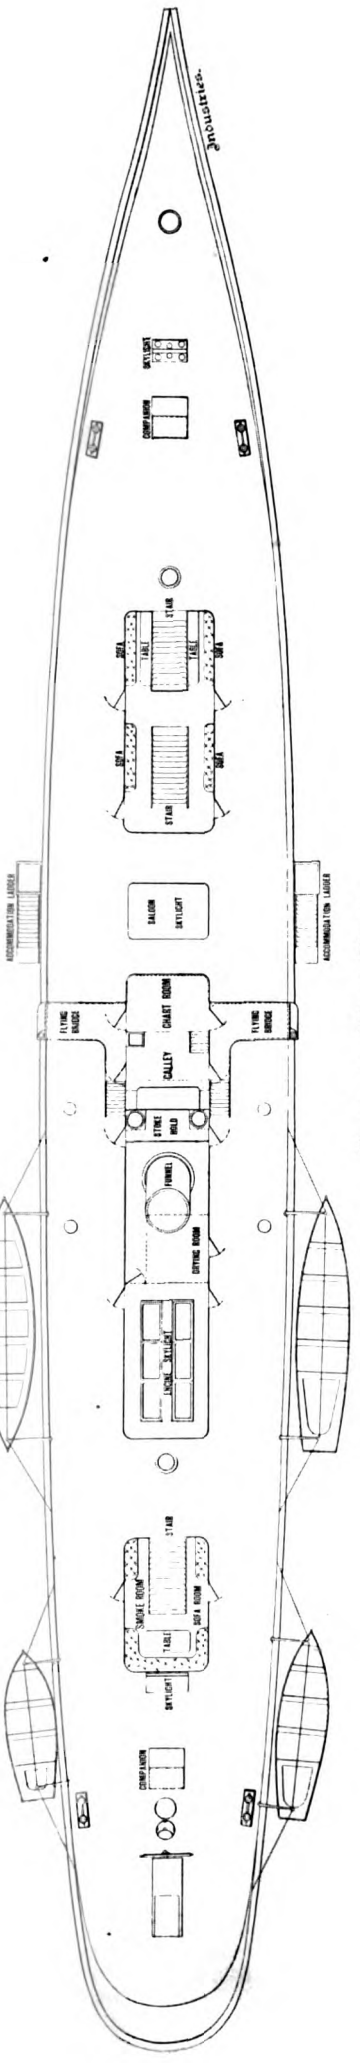
SECTIONAL ELEVATION.

Digitized by Google

and men indicated the necessity for a more thorough training than had been customary in former days, and Mr. Dyer mentioned some of the matters which ought to engage their attention.

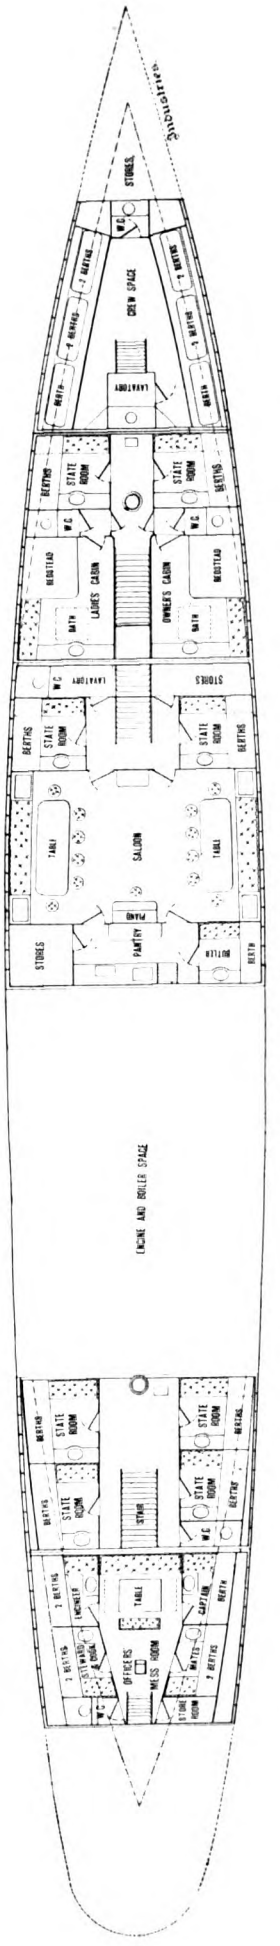
The latter part of the lecture was taken up with a brief consideration of the place of legislation in ship building and ship owning, and undue interference on the part of the Government was deprecated. Voluntary co-operation, which will habituate men to independent activities, should be encouraged, which, while strengthening their own consciousness of personal rights, would show the ship owners that those rights can only be enforced when they respect the just claims of others. The efficient design and construction of steam ships is a collection of compromises of a great many qualities, which if carried to extremes, are incompatible with one another; and their management involves considerations which are opposed to the profit of the ship owner, or the interests of the public and the crews; and the skill with which their conflicting elements are welded into one comparatively harmonious whole, should be the true measure alike of the ship builder, the marine engineer, and the ship owner.

POSSIBLE NAVAL COMBINATIONS AGAINST ENGLAND.



Admiral Thomas Symonds has just issued an interesting table showing the probable strength of possible combinations of naval powers against Great Britain. The data from which his conclusions are drawn are those of the Parliamentary return of the comparative strength of British and foreign navies. From these figures it appears that Britain can bring into action in all 73 armour clads, 44 of which are classed as obsolete. Of the remaining 29, 15 are first class armour clads, 2 are second class, and 12 are cruisers—only nine of these last being fast cruisers. Against this navy, France can bring 63 armour clads, 26 of which are first class, 29 are obsolete, and 8 are armoured gunboats of moderate speed. Of the Italian navy there is no report of obsolete ships, though the list of 19 first class and 2 second class ships of war cannot be taken as excluding obsolete vessels, for 9 of these are more than twenty years old. Admiral Symonds assumes the possibility of a Franco-Italian combination against Great Britain, which would involve a naval struggle between 73 British armour clads and 84 armour clads of the allied navies. In the same way, a Franco-Russian alliance would bring against our fleet of 73 an allied fleet of 87. A Franco-German alliance would bring against us a combined force of 76 large armour clads and 14 small armour clads. Admiral Symonds also draws attention to the circumstance that the modern English armour clads have unarmoured ends, and that 49 out of the 73 are armed with muzzle loading guns, while the armaments of all the vessels comprised in the above possible combinations are breech loading. Admiral Symonds expresses his belief that the efforts of the French Government to secure a maritime superiority to all other nations have been successful. The superior armament of their large armour clads, and their continued activity in naval construction, have given them, Admiral Symonds thinks, a preponderating naval power. The table also enumerates and contradicts certain statements of Lords of the Admiralty and others as to the strength and efficiency of our navy.

THE STEAM YACHT "THETIS."



This handsome vessel was built to the order of Mr. J. Donaldson, of Messrs. John I. Thornycroft & Co., London. The order was intrusted to Messrs. Muir and Houston, Harbour Engine Works, Glasgow. The "Thetis" is a screw steamer of 510 tons, yacht measurement. The leading dimensions are: 166ft. 10in. on water line, moulded breadth 25ft., moulded depth 15ft. 6in. The vessel is built of mild steel, but the scantlings are the same in dimensions as if of iron. It has been built under "special survey," and is classed 100A1 in Lloyd's Yacht Register. The keel, stem, stern post, and rudder frame are of forged scrap iron. The ship is divided into nine water tight compartments by eight bulkheads. These bulkheads are absolutely water tight, there being no openings in them of any sort. They are carried to the main deck level, so that communication between the different compartments of the ship must be made by the deck. Each of these compartments, so isolated from each other, was tested under water pressure before the vessel was launched. Any two compartments may be full of water with perfect safety. In each there is fitted an independent ejector (Thornycroft's patent) capable of discharging 40 tons of water per hour, as well as a powerful hand pump. This sub-division into isolated compartments, with these mechanical appliances for the discharge of water, should an accident occur to any of these compartments, would

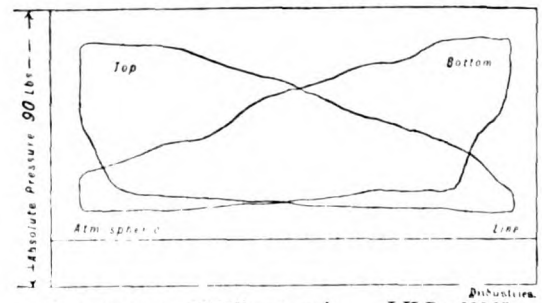
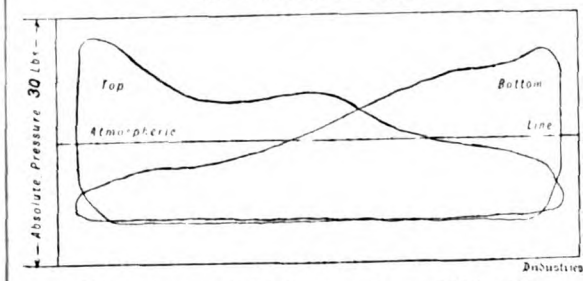
render the vessel unsinkable under almost any conceivable conditions. The general arrangement of the lower cabins is as follows: Aft, officers' quarters and state rooms, 16ft.; between officers' quarters and engine room, four state rooms, &c., for strangers, 16ft.; engine and boiler space, with cross bunker, 35ft. Engine and boiler spaces are divided by a water tight bulkhead; communication between them is through a passage in the deck house. Saloon, two state rooms, pantry, lavatories, &c., 30ft.; owner's cabin, ladies' cabin, two state rooms, lavatories, &c., 22ft.; the crew space forward is 22ft. The saloons, cabins, state rooms, and holds below are ventilated by Boyle's ventilating apparatus. Baths, heated by steam coils, are fitted in the owner's and ladies' cabins. The vessel is lighted throughout with electricity, fitted by Messrs. Muir, Mavor, & Coulson, Glasgow, as described by us on page 549, Vol. III. The steering gear is Messrs. Thornycroft's patent, and is the same as that used for their first class torpedo boats. A hydraulic transmitter is used for steering from the bridge, with alternative arrangement for steering by hand or by gear aft or at the bridge as required. The steam windlass is of special design, and is fitted with small pumps for washing the cable and anchors. The deck house over engines and boilers is built of steel, and contains chart room, galley, and drying room.



The engines, which we illustrate on our two-page supplement this week, and on pages 260 and 263, are of the triple expansion type. The cylinders are respectively 14in., 23in., and 36in. in diameter. The stroke in each case is 27in. The cylinder covers are of box section polished all over, and the cylinders are all lagged with teak. The intermediate and low pressure cylinders are both fitted with Thornycroft's patent equilibrium slide valves. In the surface condenser, the tube plates are of Muntz metal, as are also the studs exposed to sea water. The connecting rods and piston rods are

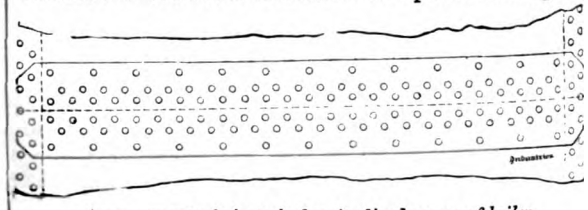
High Pressure Cylinder.



Mean pressure=87·5lb. per sq. in. I.H.P.=230.

Intermediate Cylinder.

Mean pressure=32·75lb. per sq. in. I.H.P.=236·25.



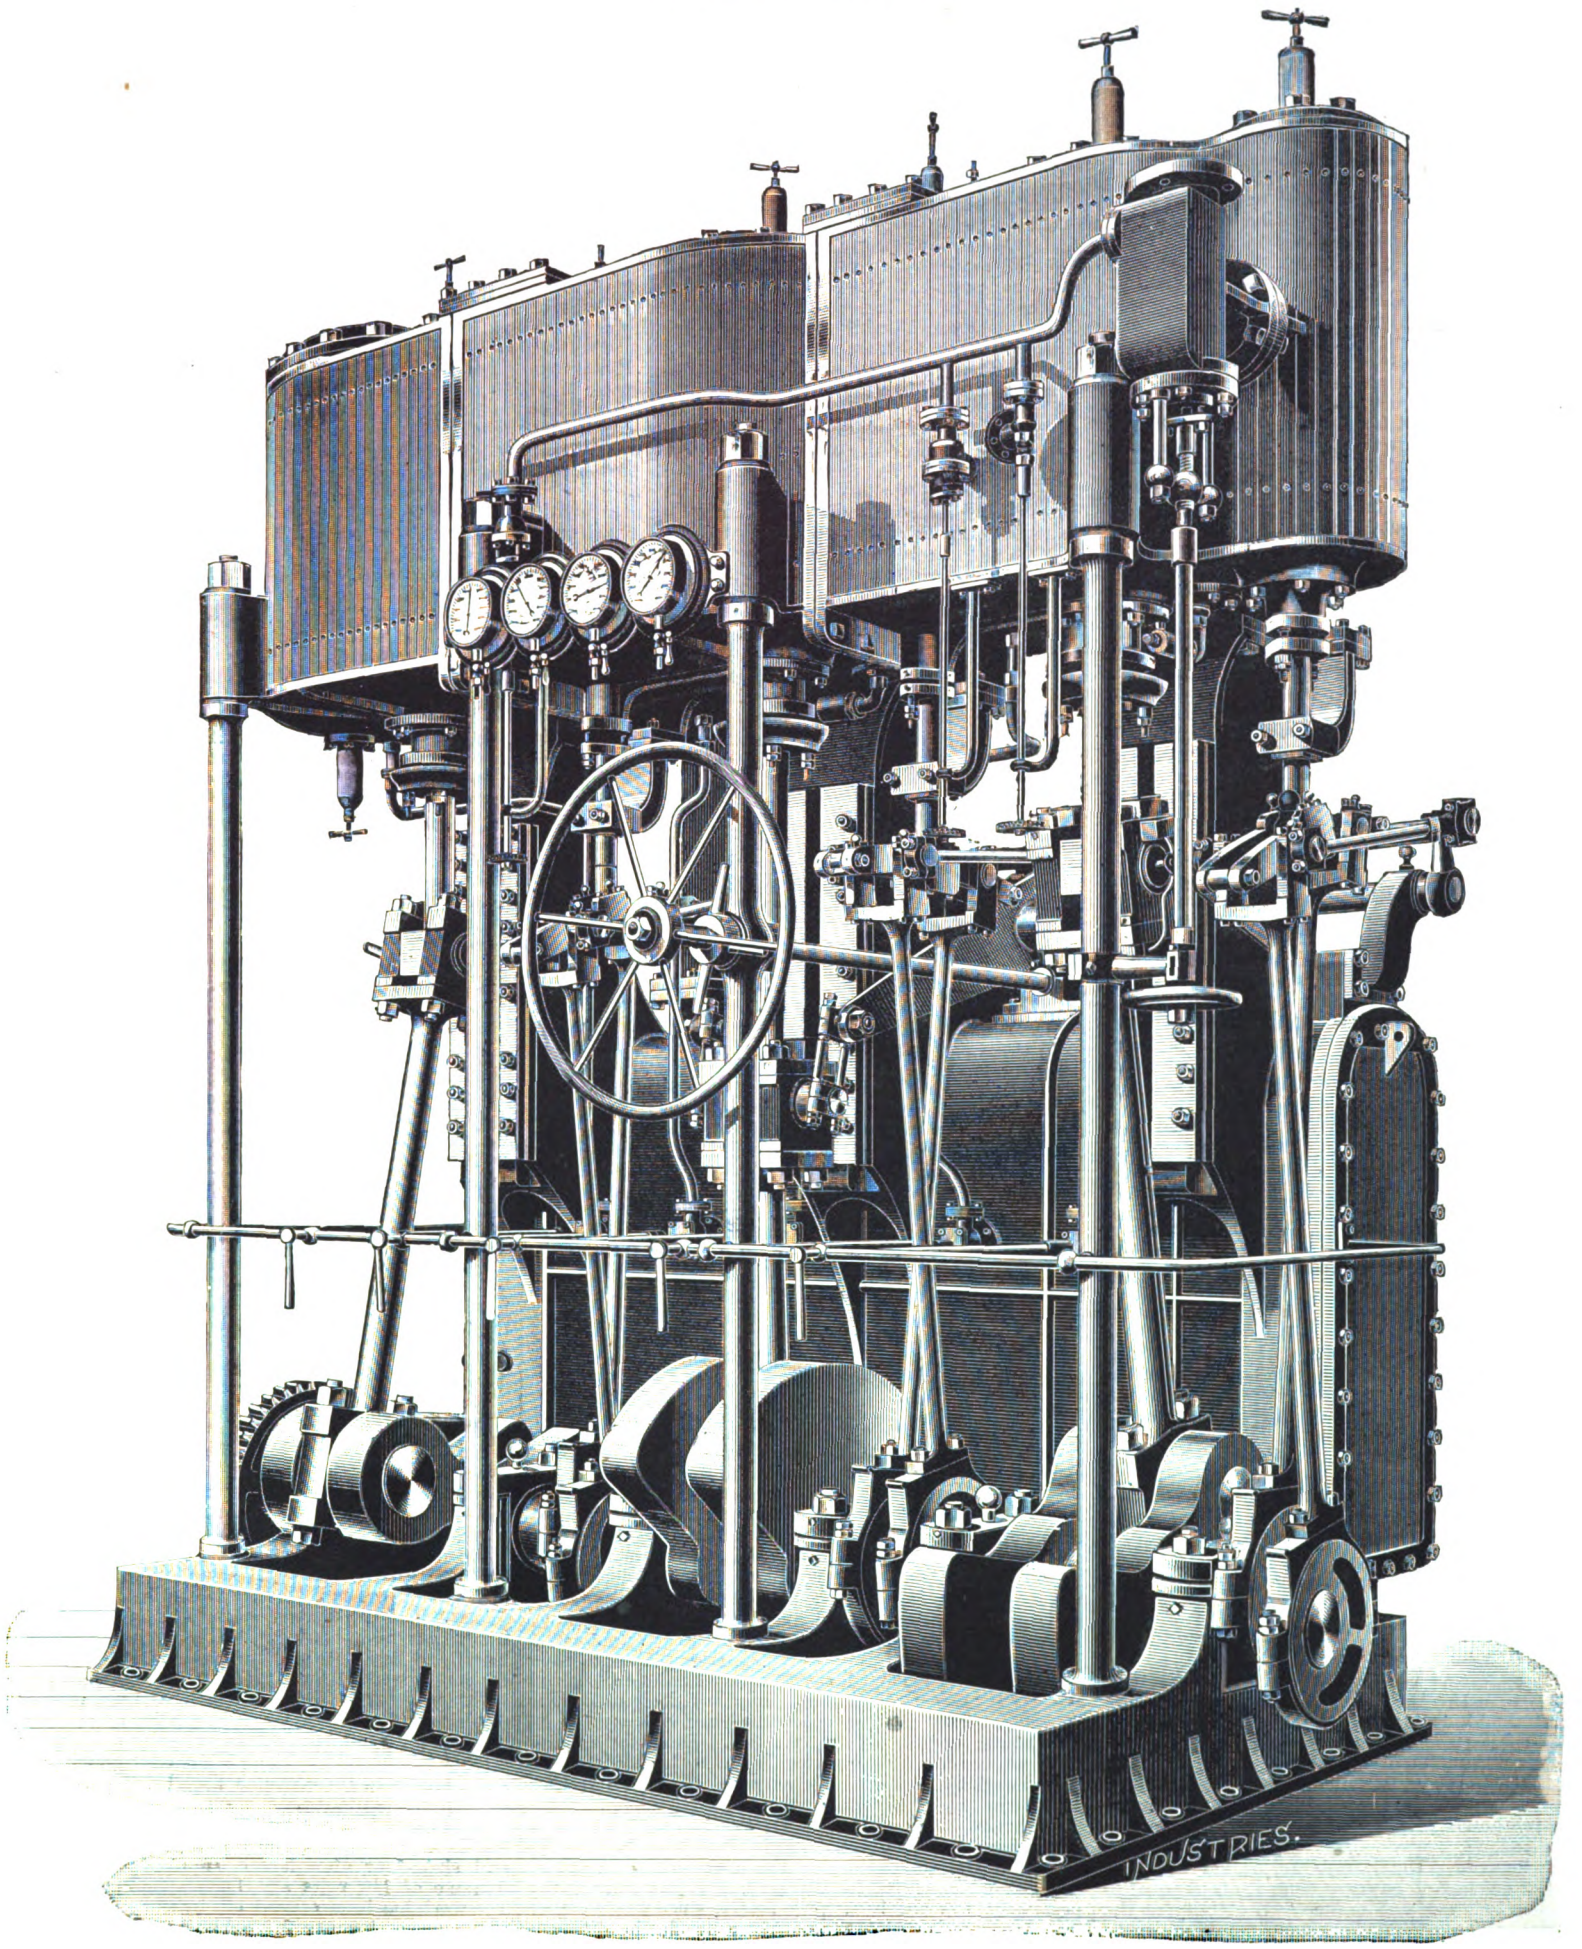
Low Pressure Cylinder.

Mean pressure=12·725lb. per sq. in. I.H.P.=224.

of forged scrap iron. The air and circulating pumps are worked by levers from the intermediate engine. There are two feed pumps and two bilge pumps; valves, valve chests, &c.—all of these being of brass. The crank shaft is built of selected forged scrap iron, and is 7in. diam. The thrust block is on the horseshoe principle, with rings of gun metal fitted to collars on the thrust shaft. There are two intermediate blocks with patent metal strips on bottom half. The propeller is made of a mixture of cast iron and steel scraps.

The main boiler, illustrated on pages 260 and 262, is made of Siemens-Martin steel, and is of the cylindrical return tubular type. It is constructed to Lloyd's requirements for a working pressure of 160lb. per square inch. The shell of the boiler consists of five plates running the

Arrangement of rivets in longitudinal seams of boiler.



full length of the boiler. The circular seams are double riveted, and the longitudinal seams are triple riveted, as shown in the illustrations. There is, in addition to the main boiler, an upright donkey boiler made for a working pressure of 60lb., to supply the electric engine when there is no steam in the main boiler. We give above diagrams taken from the engines while running at their normal speed, and also a diagram containing the performance curves.

FOREIGN INDUSTRIES

(From our own Correspondents.)

PARIS, 13TH MARCH, 1888.

THE IRON MARKET.—People are beginning to ask whether the evils attending the existence of the middleman do not outweigh the advantages. The question has been raised by the Paris iron merchants, who seem bent upon committing commercial suicide. The weather, the rupture of commercial relations with Italy, and the uneasy feeling resulting from the death of the German Emperor, have combined to check the course of business. Alarmed by what calm judges regard as merely a temporary lull, the merchants have sought to force the market by concessions in prices, thereby disorganising the trade, that seemed to have been placed on a secure basis. The irritation on the part of the manufacturers is great, and there are muttered threats of extending the practice of dealing directly with the consumer. The latest reports from the provinces describe the state of trade everywhere as quiet. The North is disturbed by labour disputes; but here and there we see continued activity. Thus the demand for wire in the Haute-Marne, and for plates in the Nord, is unabated, and both bars and plates constitute an animated market in the Ardennes. The near prospect of war, which obstructs business generally, acts as a stimulant in some directions. Thus large orders are being received by the great steel works on account of the navy and coast defences. The statistics of production in the second half of 1887 show great activity in the later month of the year. The output of forge pig amounted to 620,524 tons, against 610,319 tons in the first half year; of foundry pig to 195,684 tons, against 154,250 tons; of finished iron to 395,363 tons, against 378,897 tons; and of steel to 238,160 tons, against 212,696 tons. This shows an increase of 6·74 per cent. for the second half year for pig iron, and 7·1 per cent. for finished iron and steel. The average production in the last six months of 1887 was about equal to that of the whole year 1885, which was largely in excess of that of 1886.

THE METAL MARKET.—Stocks of copper have again increased, according to last week's reports. The syndicate has so far prevented a relapse in prices, but the present state of things cannot be long maintained It is generally believed here that although a sudden collapse is not to be looked for, prices must gradually recede. The efforts which are being made to increase production, aided by a restricted consumption, will operate, slowly perhaps, but continuously, to depress the market. The Société des Metaux held a meeting on Saturday, at which a report was read claiming for the Society the credit of having saved the copper industry from ruin. It was stated that the purchases made by the company in excess of their requirements have been sold at a remunerative price to Mr. Secretan, on the understanding that he engages to return them to the company at the same rate if they require him to do so. An extraordinary meeting is to be held, at which a proposal will be submitted to increase the capital by £1,000,000. Last year's profits amounted to £640,000. Speculation in tin in Holland has occasioned some buying here, with the result that prices have gone up from £3 to £5. Rumours of a combination between the principal lead mines of Europe and America have had the effect of bringing about a rise of 4s. Spelter is weaker by about 4s. per ton.

INDUSTRIAL SUCCESSES.—The Russian Government has, it is said, decided to remodel its war material within the next three years. The Bange gun having been preferred to the Krupp, the Cail Works will be called upon to furnish what is wanted in that department. The steam dredger built by Henri Satre, of Lyons, for the port of Santander, having been proved capable of raising 186 cub. metres an hour, a quantity greater than that required by the specification, the Spanish Government has given other important orders to the same firm for the harbour of San Juan, at Porto Rico.

AGRICULTURE AT THE PARIS EXHIBITION.—The Minister of Agriculture has decided to acquire for the great Exhibition of 1889 the means for comparing the present state of agriculture in France with that existing previously to the year 1789, and for setting forth the changes which have taken place in the interval of one hundred years. To this end he has issued a circular calling upon the Prefects to search the departmental and municipal archives for documents relating to the subject, and to obtain from local societies all the information they may be in possession of. The result of this inquiry should be a very interesting collection of documents and specimens of more than national importance.

BERLIN, 12TH MARCH, 1888.

THE COAL MARKET.—The coal market is fairly active. As compared with the beginning of the year, the prices at present obtainable are somewhat higher. The demand for coke and coking coal is also good, and prices are rising. Owing to the continuation of the cold and frosty weather, coal for domestic purposes is still in good request. Bore holes have been sunk in the district of Düderode and Osterode in prospecting for lignite, and enormous deposits have been found.

THE IRON MARKET.—The German iron market continues firm, and the amount of business done is about equal to that of the previous week. The increased activity of the iron foundries in Upper Silesia has caused more inquiry to be made for scrap iron, in which material an advance in price is imminent. Forge pig is quoted at from 50s. to 54s., and foundry pig at from 56s. to 58s. A fair demand exists for waggon wheels, sleepers, and for water pipes. The demand in the latter article is due to the damage done by the severe frosts. Merchant bars for home consumption are quoted at 140s., special sections at 155s., and boiler plates from 160s. to 165s. Foreign competition, as was to be expected in the present position of the syndicated trades, is beginning to make itself severely felt, and has already forced the rolled iron syndicate to adopt the special measure of leaving open the prices for materials supplied to the Hamburg free port district up to next October. This measure is directed more especially against English imports into the free district of Hamburg, which have lately considerably increased. The association of sheet makers met on the 8th inst. at Siegen, and resolved to establish a common sales bureau for the northern part of the Westphalian district. The base price has been increased from 150s. to 152s. for the home district, and to 165s. for Schleswig-Holstein.

THE FOREIGN TRADE OF GERMANY.—Statistics have now been issued concerning the export trade of Germany during January, 1888. In cotton goods the total quantity exported amounted to 2693 tons, as against 2799 tons in the same period of the previous year. There was also a reduction in the export of iron goods; but in cement there was a considerable increase, the quantity exported during January, 1887, amounting to a little over 8000 tons, whereas during the same month this year over 10,000 tons were exported. In spirit there is also an increase from 5652 tons to 7218 tons. Sugar, on the other hand, has slightly declined, the figures being 36,144 and 35,447 tons respectively. Paper and paper goods have risen from 6760 tons to 7961 tons. The imports of breadstuffs have under the new increased tariffs considerably declined.

SALT.—Representatives of salines and salt mines recently met at Halle with a view to syndicating the trade, or if that should not be feasible, to agree at least upon an increase in price from the 1st April next amounting to about 1s. per ton. The Government salines of Prussia, Bavaria, Würtemberg, and Baden abstained from sending representatives, and private mine owners fear that the Government works will oppose their policy of artificially forcing up prices. They have requested the Government salines to enter into contracts with the private salines, under which the former would agree not to undersell the latter; but up to the present no favourable reply has been received. If the Government salines hold out, one of two things will happen. The private works will either give up their policy of concerted action, or they will begin to undersell the Government salines, so as to bring them to terms.

AID TO NATIVE INDUSTRY.—To aid in promoting the interests of the manufacturers, the German railway authorities and ship owners have agreed to remit, the former 50 per cent., the latter 25 per cent. of the freights on all goods consigned to Melbourne for the great Exhibition of this year.

THE MANUFACTURE OF GLOW LAMPS.—The company which manufacture the Seel glow lamp in this town are about to considerably enlarge their works. The lamps have proved so economical and lasting that the demand has of late greatly increased. The necessary machinery and apparatus for the enlargement of the works have been ordered from Messrs. Fritche & Pischon, of Berlin, who make a specialty of apparatus for the manufacture of glow lamps. With the new plant, the time required to evacuate the lamps is much reduced, and the loss of quicksilver, sometimes occurring through breakage of the old Sprengel pumps, is also said to be avoided. It was often found that when a pump broke, quicksilver found its way into the clothing of the workpeople, and to protect them from such accidents, which are prejudicial to health, the pumps will be placed outside the work rooms. In adopting this precaution the company have anticipated the objection which sooner or later is sure to be raised by the sanitary authorities against the indiscriminate use of quicksilver in the manufacture of incandescent lamps.

VIENNA, 12TH MARCH, 1888.

THE IRON MARKET.—The condition of the crude iron market in Austria-Hungary has not materially changed since my last report. For finished iron the market remains firm. Business in bar iron is fairly active, but the demand for sheets has somewhat fallen off. Works are fairly well employed, and it is expected that large orders for locomotives and railway waggons will shortly be given out by the State railways. The syndicated iron works in Austria-Hungary recently decided upon an increase in the price for girders of 8s. per ton, which came into force on the 1st inst. This increase in price shows that a good spring trade is expected, and that if peace be maintained an active business in building iron and other sections is probable. The axletree syndicate have also agreed on an advance in price of 16s. per ton, this increase being attributed to the high price which has to be paid for the raw material. Following the example of other branches of the iron trade, the works manufacturing ploughs have now formed themselves into a syndicate, with a view to improving their condition. That this step has been taken is not surprising considering the depressed state of the small iron industry. In Hungary, business during the past week has not been very active, since the weather has been unfavourable and river traffic is difficult. Building operations are therefore somewhat delayed, and warmer weather is much desired. The prospects of an active building season are good, and many private and public buildings are already in progress. In railway material the demand is fairly good, and it is expected that large contracts will shortly be given out for sleepers and rails. The metal market remains firm. A new company, with a capital of £90,000, has been formed for the exploitation of tin mines in the neighbourhood of Karlsbad, in Bohemia.

ELECTRIC LIGHTING.—The town of Temesvar, which was one of the first to adopt the electric light, is now about to extend it. At present the lighting is on the series system, using Brush dynamos, arc lamps, and groups of incandescent lamps; but as this system does not lend itself easily to indoor use, where each lamp must be under independent control, a scheme has been elaborated by the resident electrician for the use of alternating current machines and transformers. The particular type of transformer to be used is that made by Messrs. Kremenezky, Mayer, & Co., of this town. A very interesting electric light installation was started at the beginning of this month at the Künstlerhaus, where a jubilee exhibition of pictures is now being held. The building dates from the year 1868, but has been repeatedly enlarged. In December last year the council resolved to abolish gas and substitute for it the electric light throughout. In making this installation, care was taken to arrange the lighting in such a way that the current might at a future time be supplied from a central station. At present the current is supplied by engines and dynamos erected in a shed some distance behind the premises. The engine house stands on the brink of the river Wien, where the ground is very treacherous, and a foundation of piles had therefore to be provided. The motive power consists of two semi-portable engines, each of about 400 sq. ft. heating surface, one supplied by Marshall, Sons, & Co.—the other by the Austrian State railway works. Each engine drives a large Drexler dynamo, which is a close imitation of the Hopkinson type. The machines are shunt wound, and have bar armatures, the output being 800 ampères at 70 volts. The circuits from the engine house consist of four naked copper cables ·86in. diam., carried on posts and insulators over the roof of an intervening house to about the middle of the roof of the Künstlerhaus, below which point is fixed the distributing switch board. The installation comprises 70 arcs for indoor use, 8 arcs for outdoor use, and a trophy of 30 glow lamps. All the arc lamps are arranged in parallel, and are of different candle power, consuming 10, 12, and 15 ampères according to the special artistic effects required. For lighting the buffet, and some rooms without windows, there is a second small plant of gas engine, dynamo, and eight arc lamps in series. The installation has been erected by Messrs. B. Egger & Co., of this town, under the superintendence of Herr von Pichler, the engineer to the Künstlerhaus. The erection of the machinery house and machinery occupied only fourteen days. Immediately over the engine house pass about two hundred telegraph and telephone wires; but as yet no disturbance from the heavy currents has been noticed in these wires.

BRUSSELS, 13TH MARCH, 1888.

THE COAL MARKET.—The price of industrial coal is well maintained, and for April delivery an advance of 10d. per ton is asked. The stoppage of canal traffic continues to prove very inconvenient. Large coal is quoted at 16s. to 16s. 10d. per ton; unscreened, 8s. 10d. to 9s. 7d.; small, 6s. 5d.; coke dust, 6s. 10d.; coke, 11s. 2d.; half washed coke, 12s.; washed coke, 13s. 2d. The Mons market is firm, and sellers obtain their own prices, while no one thinks of objecting to the higher rates for coke. At Charleroi business is also satisfactory.

THE METAL MARKET.—The market is very firm, owing to the high price of pig iron. The Athus Company have fixed their rate at 38s. 5d. up till September. At Charleroi the rates are 48s. for special brands of foundry pig, and 44s. for ordinary foundry pig. The syndicate will have no difficulty in maintaining their price so long as orders for finished iron do not decrease; otherwise rolling mills would not be able to pay current rates. Some more contracts will be made by the State railways at the commencement of next month. The Belgian rail makers' syndicate, which was dissolved at the close of last year, is to be re-constituted. Business is good in sheets, angle iron, tyres, and light rails. Messrs. Le Fèvre have contracted for the railway station of Kinkenpois, near Liège, for £13,958. La Métallurgique has received some important work for Nice, La Franco-Belge has obtained an order for a number of locomotives for the Mediterranean Railway, and Thy-le-Château has orders for Switzerland. Owing to blast furnaces being re-lighted, and to the introduction of English Nos. 3 and 4 pig, the prices of the raw and finished material are now somewhat more in harmony with each other.

GLASS WORKS.—Good orders have been received from America, not only for the best quality of ordinary glass, but also for coloured and fancy descriptions. The English market is improving. There is a good demand from Japan, and freights to the extreme East being lower, orders are coming in from China.

ELECTRIC LIGHTING.—The Dyle-Bacalan engineering works have installed the electric light, thirty arc lamps and sixty-four glow lamps, supplied from a Lahmeyer dynamo of 110 volts and 110 ampères, being employed. The work has been carried out by the Société Industrielle of Brussels. Twenty Jablochkoff arc lamps, which have been used hitherto, have been discarded.—M. Vlierboom

Digitized by Google

has fitted up a house in the Boulevard Bischoffsheim with the electric light. He uses twenty Gadoh accumulators of 44lb. each, including the weight of the glass cells. Each cell contains nine plates. The daily discharge of the battery is about forty ampère-hours, but reaches occasionally sixty. The battery is charged from a Gerard dynamo driven by a 1 h.p. Körting gas engine. In another private installation twenty-five Gadoh accumulators, weighing altogether 10cwt., are used for thirteen Khotinsky lamps of 1 ampère and 50 volts. The dynamo is driven by a 2 h.p. Lenoir gas engine.—The house of M. Lepage, Chaussée de Wavre, is entirely lighted by arc and glow lamps from the Thomson-Houston station, which supplies the Molière Theatre. Another house in the neighbourhood will also instal the electric light.

Belgian Foreign Trade.—A comparison of the foreign trade of Belgium during January last, and in the same month of 1887, shows a diminution both in the exports and imports over all. The trade with France and England, however, shows an increase.

Fountain Lighting at the Exhibition.—The illuminated fountains to be used at the Brussels Exhibition will be of a different character to those used in London and Manchester. Only one very powerful arc lamp will be used, and special effects obtained by the differential rotation of two coloured glass discs. The rays will strike a mass of pulverised water produced by revolving nozzles, and by this means a more brilliant effect is expected with only half the power which would otherwise be required.

Signalling Balloons.—Two Bruce signalling balloons, one 20ft. and one 15ft. diam., will be shown at the Brussels Exhibition, each being fitted with six glow lamps supplied from 25 E.P.S. storage cells.

DÜSSELDORF, 12th March, 1888.

The Iron Market.—It is not easy to account for the present animated aspect of the iron market. On the whole there is little or no abatement of the activity which has distinguished the iron trade of Germany for some months past, and judging from outward appearances business is likely to continue brisk throughout the current year. But the situation is not so firmly established as it appears to be. The foreign trade is suffering severely from the effects of high prices, and it is hard to see how, with dear ore and coke, the blast furnace owners are to afford to the manufacturers of finished iron and steel who work for the foreign markets, that relief in prices which it has been proposed to make. But symptoms of returning languor are not wholly absent from the home trade. Bars are less sought after, and are likely to be more neglected now that the price has been further advanced 2s. 6d. per ton. The demand for pig iron continues brisk, and is amply sufficient to absorb the production. The quantity available for consumption in the first month of the current year, that is, the production and imports, less the exports, amounted to 346,164 tons, against 286,595 tons in January, 1887, an increase of 59,569 tons, or 21·1 per cent. Spiegel is still in strong demand, and forge is more sought after. Dealings now take place for delivery in the third quarter. There is a very brisk inquiry for basic steel pig, but Bessemer is somewhat neglected. Except for bars, the finished iron and steel markets are fairly animated. A large business is being done in plates, the current prices, £7. 5s. for common, and £8. 5s. for boiler plates, being willingly paid. Common plates rolled from ingot iron sell at £6. 15s. and £7. Sheets are in moderate demand at £7. 10s., with a prospect of an increasing business as the season advances. Hoop iron sells readily at from £6. 15s. to £7. The market is dull for steel wire, the home price of which is £6, and the export price from £5. 3s. to £5. 5s. per ton. Steel works generally are fully employed. A statement in a Belgian journal to the effect that negotiations are in progress between Belgian and British manufacturers to establish a syndicate for the purpose of raising the export prices of finished iron has had a favourable influence on the market here.

German Iron Abroad.—The Customs returns for the first month of the year fully justify the apprehensions of those who see in the existing abnormally high prices a serious obstruction to the development of our foreign trade. The following are the exports in January, compared with those of the same month of 1887: Pig iron, 13,585 (19,879) tons; scrap, 1982 (4417) tons; half wrought iron, blooms, ingots, and puddle bars, 2390 (3277) tons; finished iron, bars, angles, and plates, 15,965 (21,175) tons; wire, 19,427 (21,043) tons; rails, 6691 (16,449) tons; other railway iron, 3153 (2536) tons; and manufactured goods, other than machines, 15,229 (13,332) tons; total of all classes, 78,422 (102,108) tons—a shrinkage of 23·2 per cent. In finished iron, the falling off is chiefly in bars. While the exports have diminished, the imports have increased, the total of all classes imported in January being 16,230 tons, against 14,856 tons in the same month of last year.

Locomotives for Italy.—The great engineering firm of Henschel & Son, of Cassel, has received an order for twenty powerful locomotives for the Italian Mediterranean Railway. This further proof of a growing commercial intercourse with Italy is also evidence of the good reputation which German manufactures have acquired abroad.

English Competition at Hamburg.—English competition in iron at the free port of Hamburg is making itself severely felt. The syndicate price for bars is now £6. 5s. English bars of equal quality can be delivered in Hamburg at a cost of £5. 8s. To meet this competition, the German rolled iron syndicate is compelled to deliver to the Hamburg merchants, whose purchases amounted last year to 13,200 tons, at the same price, viz., £5. 8s.; but, with forge pig at 53s., that price must leave a loss on the transaction.

LILLE, 13th March, 1888.

Textile Manufactures.—The cold weather, which begins now to break up, and the disturbing event which has occurred at Berlin, acting upon a feeble market, have further retarded the course of business in textile goods. The week has been a period of average activity in linen fabrics, the record of business transacted at Armentières being but slightly below that of the preceding week. But the woollen trade of the Roubaix-Tourcoing district has become weak generally, and almost lifeless in some particulars. Prices have a downward tendency all round. Business in piece goods is at a standstill. Buyers have a full stock of summer goods, and until these have been dispersed they are reluctant to enter into engagements for winter stock. The Calais tulle trade is moderately active, and the prospect for the spring is encouraging, but prices are very low. The article most in demand is "chantilly." A Roubaix correspondent writes me that "a movement has been set on foot by some of our most influential manufacturers to establish here a practical school of commerce for the better training of those who are destined to follow commercial pursuits."

Flax and Yarn Markets.—There is still a strong current of business in home grown flax, both for home consumption and for export, and prices are in consequence very firm. A good deal of Russian flax has changed hands. The demand for yarns is still brisk, and prices remain firm. Tows are somewhat less sought after. In jute yarns there is still a fairly animated market. Italian hemp is more inquired after, and holders are asking higher prices. The Ghent market for flax is less active; but as the supply falls off, prices are firm.

The Iron Market.—Business in iron has lost some of the vigour which characterised it a week ago; but the tone of the market is hopeful and strong. Perhaps the chief disturbing cause has been the manifestation of a spirit of discontent among the workmen. Several strikes have occurred, involving a large number of hands. The men claim an advance in the rate of wages, to enable them to benefit by the higher prices now current. The Hallez Works at Louvoil have received an order from the Western Railway Company for 100 tons of fish plates, at the price of £10. 8s. 5d. a ton; and the Sirot-Mallez Works at Thiout have obtained from the same railway company an order for 250 tons of tarred chair pins at £11. 3s. 2d. a ton. The Northern Railway Company have ordered for trial from Van Kalek, of Valenciennes, 40,000 steel chair pins manufactured hot. The price is £14. 8s. a ton.

Steam Tramway.—The General Council of the Ponts et Chaussées have decided to adopt steam traction on the new tramway between Lille and Tourcoing.

The Sugar Trade.—The annual consumption of sugar in France amounts to about 425,000 tons. Last year the yield of home grown beets fell a little short of 400,000 tons. Thus France must import about 25,000 tons to supply the deficiency. Had the season been favourable, there would have been an excess of about 100,000 tons for export. In view of the reduction of stocks which must result from the deficient yield in all the beet growing countries of Europe, French growers would have considerably increased their average of 1888 had not the situation been rendered uncertain by fresh legislation and the proposed abolition of the system of bounties. As it is, the extent of land under beet will be practically the same as in 1887, so that the advantage will be left to our rivals the Germans. The knowledge of this fact intensifies the bitter feelings roused by the Bounties Conference, and renders the opposition more stubborn.

MADRID, 12th March, 1888.

Pig Iron.—In a recent letter I referred to the termination of the agreement between the pig iron makers of Bilbao. This has led to the market being very unsettled, and at this moment there are no reliable quotations for pig iron at Bilbao, either for home consumption or export. The rates, however, are much under those which were fixed by the syndicate.

Steel Making in Asturias.—The Naval Department contracted some time ago for the supply of 3000 tons of steel with Messrs. Duro & Co., of La Telguera. The firm placed their steel making department under the charge of M. Langhalle, the French engineer. They then found that they could not obtain the desired quality of steel by the ore process, and began to use scrap iron. Since then their gas furnace has failed, and the naval authorities have ordered the material from England.

The Barcelona Exhibition.—It is now evident that the Exhibition cannot be opened as intended by the 8th of April, and the King's birthday—the 17th of May—is now spoken of as the date of opening, though it is doubtful whether the Exhibition will be in readiness even then. The applications for space have been very numerous, and it has been found necessary to enlarge the annexes. A large building, which is to be used as an hotel while the Exhibition lasts, has been very rapidly built, the time taken being only fifty-three days.

Mining Statistics.—The value of the mining statistics of Spain will be much improved in future, as a central office has been established by the Government at Madrid, whose duty it will be to collect accurate statistics. Up to now, the data have been obtained in a loose manner from the mine owners themselves, and nothing was done to ascertain whether they were correct or not. As the owners have to pay a duty on the area mined, and also a duty of 1 per cent. on the gross production of each mine, they naturally were interested in understating the extension of mines and the quantities extracted. The present statistical office has power to make investigations, and is to assist the Finance Minister in recovering duties. It is estimated by the office that on an average the underrating amounts to 40 per cent.

Huelva Sulphur Fumes.—According to the semi-official press, the Government intends coming shortly to a decision on this long disputed question. M. Sundheim is at present in Madrid as the representative of the Rio Tinto Company.

Coke Furnaces at Bilbao.—The coke furnaces which are being built at Bilbao on M. Carvés' plan at the works of the La Viscaya Companyare now nearly finished. The coal for these furnaces will be procured from England, and it is expected that the coke can be produced at a cheaper rate than it can be imported. Owing to the amount of handling it undergoes the imported coke has the disadvantage of containing a large proportion of dust.

NEW YORK, 3rd March, 1888.

The Coal Market.—The coal market is practically unchanged. Supplies are increasing slowly, as nearly all the Schuylkill miners have returned to work. Prices are still high, with apparently no tendency to fall; but if the present increased production be continued prices will soon drop back to their normal figure. The bituminous market is quiet. It is probable that the present rate will be maintained during the coming season.

The Iron Market.—The settlement of the strike is expected to increase the business in pig iron, but no change in the market has yet taken place. There is more demand for bars, several large orders having been placed during the past week. The Pennsylvania Railroad hast just placed orders at their Altoona shops for the construction of one hundred engines and 3500 freight cars; and 2200 cars and seventy locomotives have been contracted for with outside parties. There is more business being done in plate and tank iron. Mills are, however, not working to their full capacity, and prices are unchanged. Steel rails are in fair demand, but there have been no large orders placed lately, and prices are still about $32 per ton. In other forms steel is in pretty good request, and the mills are moderately busy.

The Metal Market.—It has been rumoured for the past two weeks, and is now positively asserted in certain quarters, that the Calumet and Hecla mines have contracted to sell all their output for three years, amounting to about 150,000,000lb., to the French syndicate, at 13 cents per lb. As these mines have hitherto been opposed to all combinations to increase the cost of copper, no great weight is as yet attached to this assertion. A fair average amount of business has been done in tin, and for March delivery prices have risen from 34·85 cents to 36 cents per lb. The amount in stock is smaller than usual, and prices are likely to go rather higher. The lead market is firm, with slightly better prices, but moderate business. Spelter is quiet and weaker. There are very few transactions, and prices are 5·30 cents per lb. for American domestic.

Corliss.—By the death of Mr. George H. Corliss at Providence in his 70th year, the engineering profession has lost one of its most eminent members. In 1846 he first turned his attention to the improvement of the steam engine, and ten years later the Corliss Steam Engine Company was incorporated. His success in building the large engine for the Centennial Exposition made him well known to engineers everywhere, and engines built after his design are to be found all over the world.

Railways.—The western approach to the Poughkeepsie bridge is rapidly being completed, a large force of men being employed in laying the track. The Erie Railroad Company is constructing a new drawbridge over the Hackensack river. There will be two passage ways, one on each side of the tower, which will allow of the largest craft passing through. The bridge will be worked by steam power. Automatic locking and signalling apparatus and switch rails will be used.

Canals.—A strong effort is being made by the representatives of New York City and Buffalo to secure an appropriation of £200,000 from the State Legislature for the New York State canals. The importance of the canals is shown from the amount of grain carried by them. While the canals were open in 1887, the receipts in New York were upwards of 75,000,000 bushels, while those of Philadelphia, Boston, and Baltimore, combined, only amounted to 33,000,000 bushels. New York received by canal alone 46,000,000 bushels, or 61 per cent. of the entire amount. The Merced Canal, which was commenced five years ago, has now been opened for traffic. The canal is twenty-seven miles long, 100ft. wide at the top, 70ft. at the bottom, and 10ft. deep. It is in the heart of the San Joaquin Valley, 140 miles from San Francisco, and runs from the Merced River, through what has been an almost barren plain, to the town of Merced, on the Southern Pacific Railway. It will irrigate 300,000 acres of land.

THE WORKING OF AN ENGLISH RAILWAY.

We are indebted to the *Times* for the following abstract of an interesting lecture, delivered on the above subject by Lieutenant-Colonel Findlay, of the Engineer and Railway Volunteer Staff Corps, at the School of Military Engineering, Chatham, on the 8th inst. The lecturer referred to the London and North-Western Railway Company's system of working as an example for the illustration of his subject, as he had an intimate acquaintance with that company's arrangement of working.

The lecturer began by pointing out the close connection between his subject and those questions which might be supposed to engage the attention of military engineers. Thus, in case of an invasion, our safety would largely depend upon the perfect equipment and efficient working of the network of railways covering these islands. The Government, mindful of this fact, had some years ago instituted the Engineer and Railway Volunteer Staff Corps, composed of engineers and the general managers of most of the principal railways, the intention being that, in case of invasion, these gentlemen should work the railways as they did in time of peace, but should act under the directions of military commanders. The railways would have to be given up to the service of the State, and he himself anticipated no difficulty in concentrating a large body of troops within a very brief period of time. In the early part of 1885, the War Office instituted a kind of test of the ability of the companies to perform this task. The attempt was, of course, only made on paper, but as far as it went it was satisfactory. The test took the form of an exercise, proposed by order of the Commander-in-Chief, and constituted, in fact, a problem to which we were required to furnish the solution. We were asked, said the lecturer, to assume that an invading force, numbering 150,000 men, had commenced to disembark on the coast between Southend and Shoeburyness, and that hostile vessels were simultaneously ascending the Blackwater river to land a strong detachment at Stangate Abbey. Instructions were supposed to be issued by telegraph for the concentration of six army corps, numbering about 130,000 men, on the line of Stanford-le-Hope, Billericay, and Chelmsford, with a view to occupy the Basildon position and repel the invader—three corps being brought up as rapidly as possible and the remainder within forty-eight hours. We were told where the troops were stationed all over the country—north, south, east, and west—and the number of men composing each division. We assumed that the ordinary traffic would be suspended for the time being, that land could be encroached on wherever necessary for the construction of temporary platforms of sleepers and ballast for loading artillery and cavalry, and for other purposes, and that all the railways could be worked as one. We submitted tables showing the number of trains required, where each would start from and the hour of starting, the route travelled, the hour of arrival, and the times allowed for refreshment and other purposes on the journey. The total number of trains employed was 515. The speed was about twenty-five miles an hour, exclusive of stoppages, the trains following each other on the same lines at intervals of fifteen minutes, and the last train was timed to arrive at Chelmsford within forty-five hours and fifty minutes of the hour at which the order was supposed to have been given by telegraph. Thus, in theory at any rate, we put our defenders in a position to drive the invaders into the sea. In the case of our being engaged in a war on the Continent, it would also be necessary that railway engineers should accompany our forces, in order to deal with foreign lines. For this purpose a beginning had been made by the embodiment last year of a force of 631 men at the London and North-Western works at Crewe. This corps is almost entirely composed of men who in their ordinary avocations are smiths, fitters, firemen, &c., and they are undergoing, in addition to the ordinary infantry drill, a course of instruction in military engineering. The lecturer then proceeded to the main subject of his address. The immense and continuous development of railway traffic during the last fifty years had, he said, taxed to the utmost the ability and inventive genius of those engaged in its management, and of constructive and mechanical engineers, in order to keep pace with it, and to admit of its being conducted with regularity and dispatch, and with a minimum of delays and mishaps. The traffic consisted of varying elements. There are, the lecturer explained, express and mail passenger trains running at a speed of forty-five miles an hour, and even more in some cases; others at a somewhat less speed; stopping trains, calling at every station, and running at a rate of from twenty to twenty-five miles an hour; local suburban trains, running for short distances at a fairly high rate of speed, chiefly for residential purposes; express goods trains between the larger towns, attaining a speed of twenty or twenty-five miles an hour; slow, stopping goods trains, for serving smaller towns and villages; and, finally, the heavy coal trains running out of the great colliery districts to every centre of population. All these various trains, heavy and light, fast and slow, some stopping at the stations, and others dashing through them at high rates of speed, have to be accommodated to a great extent upon the same line of rails, yet all to keep their time and fulfil their appointed functions—and, briefly, this is the great problem which railway management has to solve. Such a service cannot be carried on under all circumstances—whether by night or day, in fogs, in snowstorms, in wind or rain, and under all other adverse conditions—without entailing hardships and dangers upon the men engaged in the working; but it was pleasing to state that the great army of men of all grades in the employment of the London and North-Western Railway Company show at all times a state of complete discipline and cheerful devotion to duty which could not be exceeded by any body of men whatever, and which, although perhaps not so well understood or appreciated by the public as might be the case, reflect the highest credit upon them. To carry on this great traffic the main essentials are a sound permanent way, powerful and efficient engines, an ample supply of suitable rolling stock, the most perfect signalling and telegraph arrangements, especially the block telegraph system, continuous brakes, and last, but not least, a highly trained and thoroughly qualified staff. Each of the subjects thus introduced the lecturer discussed in detail. He described the system of keeping up a thoroughly efficient and experienced staff. The company, he said, began by appointing lads of fourteen as boy porters, telegraph clerks, and to other similar employments, and when these lads grew up to be men they were experienced in the various branches of employment, and were able to fill such posts as became vacant. To the training of signalmen the most scrupulous attention was paid, and their appointments were never confirmed until after a thorough examination—especially in the matter of colour blindness—they were found to be fit for the posts they had to fill. Guards of passenger trains were selected from the porters, and guards of goods trains from the goods porters and shunters, always after a rigid examination and with due regard to general intelligence, capacity, and character. For the superior positions of inspectors, foremen, station masters, and the higher grades of the service, it was the invariable rule to select men from the lower ranks solely on the ground of merit, irrespectively of seniority or any other circumstances. Thus it was no unusual thing for a station master, by reason of special aptitude, to rise to the position of divisional superintendent, and even general manager. The company were not unmindful of the material welfare of the men they employed, and three insurance funds had been established in connection with the company, by means of which the men were provided for in the event of sickness, accident, or old age. The lecturer then entered into general statistics. The total number of the staff was 55,217. The total mileage was 2548 miles; the number of engines, 2541; carriages, 4548; goods and coal waggons, 53,555. The train mileage during the year ended June 30th, 1887, was, passenger, 19,533,957 miles; goods and mineral, 18,158,107, a total of 37,692,064 miles. In other words, the engines ran nearly a mile and three-quarters every second, or 104 miles every minute, and practically they put a girdle round the earth every four hours. During the year the number of passengers was 56,465,260, and the number of tons of goods and minerals carried was 33,937,758. The revenue derived from all sources was, from passenger traffic, £4,185,818; goods traffic, £5,974,319; or a total of £10,160,137. In order to explain how the engine working was arranged, the time and speed of running, and the intersections of the trains at places where goods and slow trains had to shunt into sidings for the fast trains to pass them, the lecturer exhibited a section of the line between Preston and Carlisle. If the theory of the time bill could be realised absolutely in practice, it would represent the perfection of railway travelling; but owing to bad weather (especially fogs and snowstorms), to the fluctuations of traffic and other uncontrollable causes, this ideal could never be kept up. When the calculations of the time table were upset arrangements had to be left to the discretion of the station masters and the foremen. The most that could be done on the part of the management was to lay down certain rules and principles for the guidance of the men. The lecturer then explained the system of signalling by coloured lights, so that trains might be distinguished from one another, more especially at night. Further, he said that in the last twenty years trains had more than doubled in weight, and that the speed had increased in some cases as much as 14 per cent. In consequence new engines had to be constructed capable of dealing with greater weight and speed. Indeed, there was nothing more striking than the contrast between the primitive machines which were considered triumphs of engineering skill in the early days of railways and the magnificent engines of modern times. The engines now employed were of eight distinct types. The old engines with a single pair of driving wheels were being superseded by the compound engines invented by Mr. Webb. The engine Dreadnought had, while working a train of 321 tons over a space of 105 miles, attained a speed of forty-four miles an hour with the expenditure of 39cwt. of coal. Of course with such rates of speed it was necessary to have powerful and trustworthy brakes for bringing the trains to a stand quickly when required. The brake gear used on the company's line was of two kinds, the vacuum and the Westinghouse. The question of safety then led the lecturer to deal with the system of signalling and telegraphing the trains, and the ingenious devices employed for securing gates at level crossings, turn tables, and canal bridges. The signalling of the London and North-Western Railway had, he said, involved the erection of 1400 signal cabins containing 30,000 levers, and of 14,000 signals, at an expenditure of £2,000,000. The steel rodding for actuating the points would form a continuous rod from the Land's End to John O'Groats, while the wires which work the signals would stretch from Liverpool to New York. Electricity also was a great factor in the working of railways, and he described the system of the block telegraph used as an auxiliary to the working of the out-door semaphore signals. The total number of bells used was 4850. As to ordinary message telegraphs, the number transmitted over the company's wires during the year was 14,573,607, showing an increase of 60 per cent. during the last decade. The mileage of wire on the system was 18,115 miles, and over 100,000 coils were in work. The lecturer then proceeded, with the help of diagrams, to describe the system of shunting as carried on at Edge Hill, situated on the Liverpool and Manchester Railway—the first one constructed by George Stephenson, now nearly sixty years ago. Fogs, he said, upset the arrangements and caused anxiety more than all other elements of difficulty put together. The fog of the week ended January 14th was the most severe visitation remembered. Delays were inevitable; but with the exception of one or two trifling mishaps, the traffic, owing to the precautions taken, was carried on during the week without any actual interruption, and without accident or injury to a single passenger.

SOME RECENT REPORTS ON BOILER EXPLOSIONS.

The Board of Trade have recently issued several Reports of Preliminary Inquiry relating to boiler explosions, which we propose to notice. The first, No. 244, relates to the explosion of a small, plain horizontal cylinder boiler, with flat ends, and externally fired, belonging to Mr. William Foley, mineral water manufacturer, Cradley Heath, Staffordshire. The explosion occurred about nine a.m. on the 18th of November, 1887, without causing injury to any person. The boiler was 31½in. diam., 7ft. long, with ends flat, and attached to shell by angle iron rings 2½in. by 2½in. by ⅜in. All the plates were ⅜in. thick, excepting the upper part of the back end, which was ½in. thick. The name of the maker and the age of the boiler were unknown, it having been bought second hand by Mr. Foley in the summer of 1880, but it was evidently very old. The front end plate of the boiler was reduced in thickness by grooving internally for nearly three-fifths of the circumference close to the rivets by which it was attached to the angle iron ring, so much so that it became unable to withstand the ordinary working pressure of 30lb. to which it is assumed the safety valve was loaded, and consequently it was blown out, the boiler being at the same time projected backwards, resulting in the destruction of the chimney and damage to surrounding property. This explosion was due primarily to an error in its design—no provision having been made for stiffening the ends, so as to prevent the constant buckling and bending action going on while under pressure, which could easily have been avoided by riveting strips of T iron across the ends, or the same object could have been attained by cambering the ends sufficiently to avoid deflection—and finally, to the grooving which resulted from the constant mechanical action, due to the flat form of the ends being unnoticed on this occasion, although it is evident that on some former occasion a similar defect in the back end had been observed, and the upper half of the end replaced by a thicker plate in consequence. The boiler was neither inspected nor insured.

Report No. 245 does not refer to the explosion of a steam boiler, but to the bursting of a stop valve chest fixed upon a main range of steam pipes connecting eighteen boilers at the silk mills of Messrs. Lister & Co., Bradford, Yorkshire. The accident occurred at about six o'clock in the morning of the 25th October, 1887, by which one man was killed. The valve box and cover were of cast iron, and the valve, seat, spindle, gland, and bush, of brass. The thickness of metal at the fracture ranged from $\frac{7}{16}$in. to $\frac{13}{16}$in. The stop valve which burst, the diameter of which was $7\frac{7}{8}$in., and the pipes to which it was attached, were made and fitted about the year 1872, and no previous accident or even serious repairs had been reported.

Report No. 246 describes the explosion of the boiler of a portable engine at Newton Court, Dilwyn, Herefordshire; it was the property of Mr. Llewellyn Hancock, Westfield Villa, Leominster. The boiler was made by Messrs. Tuxford & Sons, of Boston, in 1859, and was twenty-eight years old when it exploded, on the 9th November, 1887. There is nothing to cause surprise in connection with this accident, which resulted in severely scalding one man. It was an old worn out boiler, dangerously corroded at the part that gave way, and worked with an inoperative safety valve. It was neither under inspection nor insurance.

Report No. 247 refers to the explosion of a boiler on the 26th October, 1887, rented and worked by Messrs. John Cowan & Co., Clady Bleach and Dye Works, Dunadry, near Belfast. It was a Cornish boiler, 30ft. long, 6ft. diam., plates ⅜in. thick, the flue 3ft. diam., and fitted with seven Galloway tubes, name of maker unknown and age doubtful, but was placed in position by Mr. William Weir, a former tenant of the works, in 1865; the working pressure being 45lb. In June, 1887, the boiler was moved from its seating, and the part of the shell that had rested upon the seating walls was cut out, and renewed by longitudinal strips 20in. wide. After the explosion, it was found that these strips were much wasted where they had rested on the seating walls, and reduced for a great part of the length of the boiler to about ⅛in. thick—in fact, for a short distance the thickness did not exceed $\frac{1}{16}$in. The boiler was blown into several pieces, and two men were killed. The boiler had been under the inspection and insurance of the English and Scottish Boiler Insurance Company, Limited, Manchester, since the 19th May, 1880, and their inspector appears from the Report to have thoroughly examined the boiler on the 18th December, 1882, and again on the 22nd February, 1887. Mr. Traill remarks upon this explosion that "it is hardly credible that the boiler could have been in good condition when last thoroughly examined, 22nd February, 1887, as it is not probable that such serious corrosion has taken place since then."

Report No. 248, more recently issued, refers to the explosion of a boiler belonging to Mr. John Morris, Barton-on-Humber, near Hull, which occurred on the 17th October, 1887. The boiler was of the Cornish type, 3ft. 8in. diam., 9ft. 7½in. in length, made of ⅜in. plates, single riveted, containing one flue 2ft. 2in. in diameter, also ⅜in. thick. The end plates were of the same thickness. It was provided with a stop valve, one safety valve $2\frac{1}{16}$in. in diameter, one of Schaffer & Budenberg's steam pressure gauges graduated to 80lb. per square inch, two water gauge glasses and fittings on each side of the furnace, one feed check valve, and one blow-off cock. The safety valve was apparently loaded to about 39lb. per square inch. The

Digitized by Google

boiler was made in 1866, by Messrs. Good & Menzies, Hull, and after passing through two other hands, was bought by Mr. Morris in 1883. It was neither under inspection nor insurance. The explosion was caused by shortness of water, apparently owing to the choking of the water gauge glass having escaped the attention of the attendant, but did no damage to property or injury to any person. In fact it is extremely doubtful whether anything that could be fairly called an explosion took place, as the inspector states that "the plates of the furnace were distorted gently up to the point of fracture"—1¼in. in length. According to the report "the mortar of the setting of the boiler was not disturbed in the least degree."

Five months have nearly elapsed since the last mentioned explosion took place, and yet the preliminary report was only issued a few days ago.

SHIPBUILDING NOTES.

A very successful trial trip was made last Saturday of the new s.s. "Indra," built by Messrs. Thomas Royden and Sons, of Liverpool, the machinery being made by Messrs. Fawcett, Preston, & Co. The length is 360ft., breadth 44ft., depth 28ft. 6in., gross tonnage 3,582. She is fitted with double bottoms and deep ballast tank forward. Her engines are of the triple expansion type with cylinders 27in., 44in., and 71in. diam. respectively, and a stroke of 4ft. There are two double ended steel boilers, each with six furnaces fitted with Galley's patent fire bars, the working pressure being 150lb. per sq. in. The propeller blades are of cast steel bolted to a cast iron boss.

The official trial trip of the "Hoopoe," one of the Cork Steamship Co.'s vessels, was made on the Mersey last week, when a speed of 12¼ knots was attained on the measured mile, the engines running 70 revolutions per minute. The vessel has been fitted with new machinery by Messrs. David Rollo & Sons, Liverpool. The engines are on the three cylinder, three crank, direct acting principle, with cylinders 21in., 33in., and 53in. diam. respectively, with a stroke of 36in. There are two single ended steel boilers, carrying steam at 160lb. pressure.

There was launched from the yard of Messrs. John Blumer & Co., North Dock shipbuilding yard, Sunderland, on the 9th inst., the iron screw steamer "Hampton," built to the order of the Commercial Steam Shipping Company, London. The vessel has a short poop, raised quarter deck, hurricane house, and topgallant forecastle, and has been built on the cellular double bottom system, with web frames, hold beams being dispensed with. The principal dimensions are: Length, between perpendiculars, 280ft; breadth, moulded, 38ft.; and depth, moulded, 21ft. 6in. The engines and boilers are being fitted by the North-Eastern Marine Engineering Company, Limited, South Docks. The engines are of the triple expansion type, and have cylinders 21½in., 36in., and 59in. diameter; 39in. length of stroke, and are 190 n.h.p. The deck machinery includes four steam winches, Pepper's patent steam steering gear, by Messrs. Rodgers & Co., Stockton-on-Tees; and Harfield & Co's patent steam windlass and capstan.

On Saturday, the 10th inst., Messrs. Edward Withy & Co. launched from their shipyard at Hartlepool a steel screw steamer, built to the order of Mr. George Steel, West Hartlepool, for Messrs. Steel, Young, & Co., London. This is the one hundred and fifty-second vessel on the builders' books, and the twenty-sixth built by them for the same owners. The vessel is a fine type of a modern cargo boat, is built of Siemens-Martin steel, is over 300ft. in length, with a large measurement and deadweight carrying capacity, has a long raised quarter deck, short poop, and long bridge house, with a topgallant forecastle; the main bridge, quarter and forecastle decks, skylights, bulwarks, rails, bulkheads, cargo battens, &c., are built of iron or steel. The main and after holds are built on the web frame system, dispensing with hold beams, thus enabling the steamer to carry cargoes of the most bulky description, such as machinery, torpedo boats, large guns, &c.; has a cellular bottom all fore and aft (Withy & Sivewright's patent), and the after peak will also be available for water ballast. She is fitted with four steam winches, two donkey boilers, and patent direct steam windlass on forecastle, hand and steam steering gear amidships, and patent screw standby gear aft. The accommodation for officers and passengers is under the poop aft, and is fitted up in hardwood, with beautifully hand painted panels, by the firm's lady decorative staff. The vessel is rigged as a two masted fore and aft schooner, with iron masts; and is built to the 100 A1 class at Lloyd's, under the personal superintendence of Mr. George Steel. She will be fitted with triple expansion engines by Messrs. T. Richardson & Sons, Hartlepool.

Last week Messrs. J. F. Waddington & Co. launched from their shipbuilding and engineering works, at Seacombe, near Liverpool, a handsomely modelled screw tug, called the "Sunbeam," intended for towing purposes at Belfast. She has a guaranteed speed of 10 knots, and is fitted with engines of 50 h.p.

NAVY CONTRACTS.—A parliamentary paper has been issued in which are given detailed instructions for the Director of Navy Contracts in the purchase of all stores, supplies, and machinery for the use of the marine forces and establishments, and for the conclusion of all contracts in connection with the same, and also for the Surveyor of Stores as to the examination and receipt of stores.

Notices of Meetings.

THIS WEEK.

SOCIETY OF ARTS.—Saturday, 17th March, 3 p.m. Dr. Mann Lecture on the "Protection of Buildings from Lightning," by Professor Oliver J. Lodge, D.Sc., F.R.S.

NATIONAL ASSOCIATION OF COLLIERY MANAGERS.—Parent Society. Meeting at Manchester, Saturday, 17th March, 1 p.m.—South Staffordshire Branch. Meeting at Wolverhampton, Tuesday, 20th March.

NEXT WEEK.

SOCIETY OF ARTS.—Monday, 19th March, 8 p.m. Cantor lecture on "Alloys," by Professor Chandler Roberts-Austen, F.R.S.—Tuesday, 20th March, 8 p.m. Applied Art Section. Paper to be read on "What Style of Architecture should we Follow?" by Mr. Wm. Simpson.—Wednesday, 21st March, 8 p.m. Ordinary meeting. Paper to be read on "The Evils of Canal Irrigation in India, and their Prevention," by T. H. Thornton, C.S.I., D.C.L.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, 19th March, 8 p.m. Paper to be read on "The Polariscope and its Applications to Brewing," by Mr. John Heron.

ROYAL INSTITUTION OF BRITISH ARCHITECTS.—Monday, 19th March. Ordinary meeting. Paper and discussion.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 20th March, 8 p.m. Ordinary meeting. Paper to be discussed: "Economy Trials of a Non-condensing Steam Engine—Simple, Compound, and Triple," by Mr. P. W. Willans, M.Inst.C.E.—Friday, 23rd March, 7 30 p.m. Students' meeting. Paper to be read: "Principal Types of American Swing Bridges," by Mr. Henry W. Hodge, Stud.Inst.C.E.

INSTITUTION OF NAVAL ARCHITECTS.—Wednesday, 21st, Thursday, 22nd, and Friday, 23rd March. Annual meeting.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, 21st March, 7 p.m. Address by the President, Dr. W. Marcet, M.D., F.R.S., on "Atmospheric Electricity," illustrated by experiments; after which Mr. G. J. Symons, F.R.S., will make a short communication on "The Non-existence of Thunderbolts; elucidated by accounts of searches after them, and the exhibition of specimens." Exhibition of apparatus connected with atmospheric electricity, including lightning conductors, photographs of lightning, and damaged objects, and of such new instruments as have been invented and first constructed since the last Exhibition.

ROYAL UNITED SERVICE INSTITUTION.—Wednesday, 21st March, 3 p.m. Paper to be read on "Land and Water Transport in the Soudan and on the Nile," by Major E. A. de Cosson, F.R.G.S.—Friday, 23rd March, 3 p.m. Paper to be read on "Naval Mobilisation," by Rear-Admiral Colomb.

INSTITUTE OF PATENT AGENTS.—Wednesday, 21st March, 7 p.m. Paper to be read and discussed on "The Proposed Patent Law in Switzerland," by Mr. G. G. M. Hardingham, Fel. Inst.P.A.

LIVERPOOL ENGINEERING SOCIETY.—Wednesday, 21st March, 8 p.m. Paper on "Filtration of Sewage," by Mr. Turner, to be further discussed.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—Thursday, 22nd March, 8 p.m. Paper to be read on "Electrical Stress," by Professor A. W. Rücker, M.A., F.R.S., and Mr. C. V. Boys.

ROYAL INSTITUTION OF GREAT BRITAIN.—Thursday, 22nd March, 3 p.m. Lecture on "Microscopical Work on the Least and Simplest Forms of Life," by the Rev. W. H. Dollinger.

PRICES CURRENT, 15TH MARCH.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—There has been a moderate business done during the past week at prices ranging from £81. 17s. 6d. to £80. 7s. 6d. per ton for sharp cash parcels. The French syndicate are actively continuing their negotiations with the English smelters, and it is likely that an arrangement will be completed which will embrace the whole copper trade, whereby prices will be regulated and steadied for a long time to come. Meanwhile there is very little copper going out from the manufacturers. Old stocks bought at low prices are being cleared off first, both at home and abroad. The home manufacturers of copper goods are thus being seriously affected for want of work, and the artisans are only half employed in consequence.

TIN.—Straits very steady at £166 for sharp cash parcels, three months quoted £133 per ton.

LEAD.—Spanish is slightly easier; English is also lower.

SPELTER.—Quotations are unaltered.

HOME INDUSTRIES.

MANCHESTER, 15th March, 1888.

The Cotton Trade.—The chief feature of this trade during the week has been the weakening of the prices of raw cotton, in consequence of the confirmation of the reports of the large production in America during the current year. Prices of all classes of American have fallen ⅛d., and, as consumers are generally well stocked, there is every probability of still lower rates being reached. Business in yarn has been steady, and the whole of the production is being easily disposed of. Some buyers are anticipating lower prices; but there seems to be abundant evidence that the production of yarn is not greater than the demand for it, and in consequence it is not probable that lower rates will rule. Cloth manufacturers assert that they are short of orders; but there is no desire to sell unless full current prices are obtained. Cloth producers are well under contract, and quotations are well maintained. With a falling cotton market, new contracts will only be made at lower rates, but at present the number of these is very small. In a report of the Council of the Amalgamated Association of Operative Spinners, it is urged that a margin of 2¾d. per lb. between middling Orleans cotton and 32's cop twist should be reached before the trade can be considered satisfactory. At present it is about 2½d., and many mills are making good profits.

The Merchandise Marks Act.—The inquiry conducted by the Manchester Chamber of Commerce as to the method of reeling yarns terminated on the 12th inst. Without anticipating the report of the committee, two things may be noticed. First, that it appears to be necessary to reel the yarns according to particular measurements used in different countries; second, that when so reeled, the counts of yarn and the number of hanks in the bundle should be stamped on or attached to the outer cover. If the second condition is adhered to there is no possibility of fraud, and it is probable that the report of the committee will, while allowing a wise latitude in the process of reeling, insist upon the necessity for correct marking.

The Ship Canal.—Rapid progress is being made in this undertaking, The shares show a little improvement in value, and the ordinary shares are a trifle higher than the preference. The directors have recently issued a circular to ship builders and owners, calling attention to the fact that, in view of possible charters being obtained for the port of Manchester hereafter, the top masts of steamers should not be made higher than 40ft. A considerable advance has taken place in the value of property in the vicinity of the docks, which are now in course of formation.

LONDON, 15th March, 1888.

The Money Market.—The rates charged for the loan of money this week are in advance of those recently ruling, even at last settlement. There has been a fair demand for accommodation for Stock Exchange purposes, though the account has not been remarkably heavy. The rates of discount for long periods are still moderate. Since last Thursday two events have taken place which have considerably affected the stock markets. The expectation of the Emperor William's death had depressed the foreign markets for several days, and the fears arising from the imminence of Mr. Goschen's conversion scheme had for a time adversely affected Home Government securities. But when the Emperor's death occurred on Friday, and when the terms of the Chancellor of the Exchequer's project were made known the same afternoon, the markets at once assumed a buoyant tone. The news from Berlin had been more than discounted, and was followed by a gradual recovery in all the markets. Mr. Goschen's scheme has been well received, and its equitable terms have operated favourably upon the funds. At the same time there is still a feverish anxiety in many quarters to buy stocks, which will give 3 per cent. with good security. Indian and Colonial stocks, and home railway preferences and debentures, continue to reap the benefit of this demand. The ordinary shares of the British railways have improved materially in price with the opening of the new account. As a speculative medium, copper shares have quite given place to diamonds, and the shares of the Cape companies have reached a ridiculously inflated price. Strong "bear" influences are now at work upon them; but though the bears prophecy a glut of diamonds and a fall in the price, their case is weakened by the fact that the enormous production at the Cape in the last few years has not flooded the diamond market, which is stronger now than it was a year ago. But this does not make it any less a fact that the prices of Cape diamond shares are far too high for the value of the properties.

Our Foreign Trade.—The Board of Trade returns for February are satisfactory, the exports amounting to £18,992,423, as compared with £17,255,133 in the same month of last year, an increase of 10 per cent. Nearly all the items show an improvement, the only important exception being worsted fabrics, the value of which has decreased by 12 per cent. The imports amounted to £29,532,776, as compared with £28,513,994 in February, 1887, an increase of 3½ per cent. In wheat, Indian corn, flour, and wool there have been large decreases; copper shows an increase in quantity of 28 per cent., and in value of 104 per cent.

London Chamber of Commerce.—The annual report of this Chamber of Commerce states that the past year was one of steady and progressive work. Owing to the facts which had been submitted by the Chamber to the Postmaster General and the Chancellor of the Exchequer, a new service for the dispatch of patterns had been introduced. The question of commercial education had been actively taken up by the Chamber, and besides encouraging evening classes in the Metropolis, a circular was issued to all the members of the Chamber requesting them to state what proportion of foreign labour was employed by them; for what reasons foreigners were employed, and in what respects British clerks failed to meet requirements. From replies received it appeared that foreign labour was employed because it was cheap, disciplined, intelligent, willing, and better trained than our own. It was considered that the disadvantages of the present position could be remedied only by more complete education and special training, particularly in languages.

The Paris Exhibition.—We have already in our last issue, and in that of the 3rd ult., given particulars of the terms upon which exhibits will be received at the Paris Exhibition of 1889. In connection with the electrical section, a meeting of intending exhibitors has been called by the Secretary of the Society of Telegraph Engineers and Electricians for Monday, the 19th inst., at 3 p.m., at the Institution of Civil Engineers, to make further arrangements for organising a British electrical section. The council of the Society have received notice that the following firms among others will take part in the Exhibition: Anglo-American Brush Electric Light Corporation, Limited; Clark, Muirhead & Co., Limited; R. E. Crompton & Co.; Electrical Power Storage Company, Limited; Elliott Brothers; John Fowler & Co. (Leeds), Limited; W. T. Goolden & Co.; Greenwood & Batley; W. T. Henley & Co., Limited; The India-rubber, Gutta-percha and Telegraph Works Company, Limited; and Woodhouse & Rawson, Limited. A public meeting is also to be held at the Mansion House to-morrow (Friday) to consider the steps which it is proposed to take in order to secure a suitable representation of British manufacturing arts and industries at the Exhibition.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 4th March, amounted to £1,116,180 on 15,837 miles, as compared with £1,132,727 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 128¼ miles, or 0·8 per cent., and a decrease in the receipts of 1·4 per cent.

New Pier.—A new iron pleasure pier is to be built in the centre of the Marina, at St. Leonards. It will be 900ft. long. The contractors for the work are Messrs. Head, Wrightson, & Co., of Stockton-on-Tees.

Compressed Air Cars.—Cars driven by the Mékarski compressed air engine are now being run on the London Street Tramways Company's line between Holloway Road and King's Cross. The air is compressed at a station, and stored in reservoirs which are placed under the cars, each charge allowing of a run of ten or twelve miles. The cars are fitted with air brakes, which enable them to be stopped in a little over their own length.

Rating of Machinery.—Sir W. Houldsworth has introduced a Bill in the House of Commons to amend the law relating to the rating of hereditaments containing machinery.

GLASGOW, 15th March, 1888.

Stock Markets.—The influence of the death of the German Emperor upon the stock markets was unimportant. The event had been anticipated, and there has not appeared any circumstances pointing to imminent danger of resulting European complications. Most of the home railway stocks have gone up a little; the North British Stock rose ⅜ on the announcement of the dividend.

Proposed Scoto-Irish Tunnel.—A secret survey has lately been made in the North of Ireland and on the Mull of Kintyre, with the object of arriving at data for an estimate of the cost of a tunnel across the narrow strait which separates Ireland from Scotland. It is said that Sir Edward Watkin has interested himself in the scheme; possibly with a view to prove the practicability of a long sea tunnel. It is said that the estimated cost is eight millions sterling, or about a million per nautical mile. On the Irish side the existing line of railway approaches within a few miles of the promontory which forms the nearest point of Scotland; but on the Scottish side an approach railway of about eighty miles would have to be constructed from the Lochgilphead station of the Crinan Railway, now under construction, to the Mull of Kintyre, where would be the entrance to the proposed tunnel. Even this would not give continuous railway communication between England and Ireland, for the western terminus of the short railway which is intended to connect the west coast of Argyllshire with the Firth of Clyde, is situated at Kilunn, on the Holy Loch, from which passengers have to be conveyed by steamer across the Firth to Greenock. Even though communication were effected between the Mull of Kintyre and the Oban Railway, which would bring it into direct connection with the railway system of the country, the route so opened up between England and Ireland would be extremely roundabout. The avoidance of a sea passage is of course so important an element, that even an extension of time might be calculated as not altogether condemnatory. By far the most suitable point for a tunnel, had the depth not been almost prohibitory, is the strait, almost as narrow as the other, between Port Patrick and Donaghadee. This would have given almost direct connection between Belfast and Scotland and the North of England.

Opening of New Market Buildings.—The Bazaar, as the Glasgow market is called, has been entirely rebuilt, lit with electric light, and otherwise embellished at a total cost of £20,000. The new building was formally opened on Thursday last by a commission of the Town Council.

Government Shipments and Harbour Dues.—A number of Glasgow gentlemen were members of the deputation which placed before Mr. W. H. Smith the views of the shipping interest in respect to the exemption from harbour dues of shipments to India on Government account. A considerable quantity of railway material is shipped annually at Glasgow for the Indian State railways, and these shipments are exempt from harbour dues, which are in consequence proportionally heavier upon private shippers. A considerable point was made by Mr. W. P. Sinclair, M.P. for Falkirk district, who showed that the grievance arose through the Government having taken over the railways of India from the hands of private companies. The private companies had of course to pay harbour dues, but when the railways became State property the payment of dues upon these shipments stopped. The Marquis of Hartington, who accompanied the deputation, emphasised this view very strongly.

Collision of Two Glasgow Ships.—On Friday last, during a dense fog in the Channel, two Glasgow ships, the "Tasmania," a four-masted sailing ship, and the "City of Corinth," a full-rigged ship, both belonging to Glasgow, came into a collision which resulted in the loss of the latter vessel. The "Tasmania" belonged to Messrs. P. Dennistoun & Co., and was a vessel of 2175 tons register. The "City of Corinth" belonged to Messrs. George Smith and Sons, and was a ship of 1220 tons. The "City of Corinth" was built in 1870, but the "Tasmania" was built quite recently.

Proposed Visit of the Institute of Naval Architects.—At a meeting composed of the councils of the Institution of Engineers and Shipbuilders in Scotland, the Clyde Steam Ship Owners, and the Clyde Sailing Ship Association, it was resolved to invite the Institute of Naval Architects to hold its summer meeting in Glasgow this year. The meeting will as usual take place about the beginning of August.

(From our own Correspondents.)

LIVERPOOL, 14th March, 1888.

Tranmere Ferry Pier.—The plans for the low level pier intended to replace the one destroyed in the storm before Christmas have not been approved by the Conservators of the Mersey and other officials connected with the traffic on the river. It has therefore been decided to repair the pier and restore it to its original shape, *i.e.*, a high level pier with a floating landing stage and approach bridge. The work has been entrusted to Messrs. J. Gordon Alison & Co., Birkenhead, and it is expected that it will be completed and in time for the summer traffic.

British-grown Tobacco in Liverpool.—Although a large portion of the tobacco grown in England has been pronounced by experts to be of good quality, the leaves have been subsequently spoiled in the curing. A crop grown by Messrs. Carter was placed in the hands of Messrs. Cope, of Liverpool and London, some time ago; it has now been carefully cured by experienced men, and in a short time will be offered to the public, who will then have an opportunity of testing its quality.

The Liverpool Tramway Service.—The directors of a local company have made an offer to the Tramway Company to work the cars on some of the routes by steam power, but nothing has yet been definitely settled. The City Council have sanctioned the carrying of parcels by the cars. A new class of car is being also introduced, which is a great improvement on the old ones, both as regards comfort and safety; the circular staircases are done away with, and two side flights being fixed instead. The seats are more conveniently arranged, four being fixed on the driver's platform. The brakes are worked independently by either driver or guard.

SHEFFIELD, 14th March, 1888.

The Heavy Industries.—The demand for iron and steel is steadily improving, and it is believed that the present month will show a more encouraging result, even with regard to trade in unwrought steel with the United States, which in February only amounted to £109,735, against £207,960 in the same month last year. Manufactured iron is fluctuating a little in price, but bars are quoted at from £4. 12s. 6d. to £5. 2s. 6d.; hoops, £5 to £5. 7s. 6d.; sheets, £6 to £7. One of the best indications of reviving trade is the continued demand for railway material. The Colonies, as well as a number of foreign States, are becoming exceedingly good customers. Messrs. Steel, Peach, & Tozer are very busy on steel rails; so are Messrs. Charles Cammell and Co. At their Penistone works, the latter company are turning out railway material, it is said, at the rate of over 1000 tons per week; and at Workington the output of steel rails is enormous. Messrs. Thomas Turton & Sons are doing a large trade in railway springs, and the other local firms making railway material have very satisfactory

Digitized by Google

orders on their books. The waggon builders in the locality are also well employed, and there is very general evidence of further railway development. The exports of railway material from Sheffield to distant parts last month reached £378,349, being an increase on the same month of the previous year of £168,676. Crucible cast steel castings are still in extensive request, and most of the well known engineers are well employed on heavy machinery and boilers. At the rolling mills and foundries work is plentiful, but in the armour plate mills there is no great activity. It is hoped, however, that Mr. Stanhope's statement in the House the other night means benefit to Sheffield. The promise made that the Government intends to protect our coaling stations and our naval and mercantile ports should result in some industry at the ordnance works which local firms, like Messrs. John Brown & Co., Messrs. Cammell & Co., and Messrs. Vickers, Sons, & Co., have erected. With improving trade there has been for the past few weeks a demand for plant of various kinds, a few firms extending their works, and putting down labour saving machinery. The tendency all round is to lessen the cost of production as much as possible; nevertheless, in some branches the workmen are beginning to inquire about an increase of wages, though some of them have only recently obtained regular work. Messrs. J. Sagar & Co., of Halifax, have recently supplied Portsmouth Dockyard with vertical boring machinery and sawing machinery, and have just received orders from the India Office for similar machinery for use at the Quetta Arsenal. The contemplated change in the Globe Steel Works of Messrs. Ibbotson Brothers has aroused little interest. The shareholders will make a profit out of the transfer of the concern to the London syndicate, receiving practically £87 per share of £100, of which £80 is paid up. Messrs. W. Jessop & Son's dividend of 6 per cent., as against 5 per cent. in the previous year, caused a good deal of satisfaction in local investing circles when it was declared, last Friday.

NORTH STAFFORDSHIRE, 14th March, 1888.

The Potteries.—As is usual at this season of the year American buyers are paying a visit to the district, and some satisfactory orders are being booked. Owing to the keen competition which prevails, however, prices are low, and the margin of profit very small. Most of the expensive and highly finished products of local manufacturers are consigned to the United States. The home trade is also improving to some extent, and those firms dealing in special lines report business to be improving. Mr. T. Twyford is building an extensive manufactory close to the main line of railway between Stoke and Etruria stations, and the work will shortly be completed. Fuel for manufacturing purposes is in fair request, and prices rule from 7s. to 8s. 6d. at the pits according to quality. Greatrow coal is extensively used for "biscuit" ware.

Miners' Federation.—The monthly meeting of the local federation was held at Tunstall on Monday last, Mr. Thomas Booth, president, in the chair. Mr. Enoch Edwards explained what had been done with regard to the case of the dismissal of a checkweighman by order of the stipendiary magistrate, the particulars of which were reported in *Industries*, and the steps he had taken to bring the matter under the notice of the Home Secretary through Mr. Fenwick, M.P. The question is to be raised at an early date before a national conference of miners. After considerable discussion on the Employers' Liability Act, the following resolution was unanimously passed: "That this Federation learns with satisfaction that active steps are being taken to make the Employers' Liability Act compulsory, to extend the time of giving notice; and pledges itself to assist in every legal way to bring about this change." The substitution of uncertain litigation and the consequent friction between employers and employed, for a system of mutual insurance by which relief to injured workmen or their relatives is assured, appears to be an object which ought not to commend itself to the intelligence of miners' delegates.

DERBY, 14th March, 1888.

Technical Education.—In his address at the recent distribution of prizes of the School of Art and Technical Institution, Derby, Sir Philip Cunliffe Owen said that he hoped the Corporation would take up the question of scientific and technical education as a matter which belonged exclusively to the ratepayers. The committee are taking steps to introduce instruction in the following subjects: (1) Dyeing, (2) the chemistry of colours as used in enamels and china painting, (3) photography, (4) wood carving and metal chasing. For this purpose the erection of a chemical laboratory is contemplated.

Butter Factory.—At a meeting of the Derbyshire Dairy Farmers' Association lately held at Derby, the scheme of Mr. Gilbert Murray was approved, for the erection of a central factory in this town for the manufacture of butter. Mr. Murray pointed out that the success of the Normandy farmers was probably due to their adoption of the factory system, the extensiveness of which may be inferred from the fact that a London firm pays £30,000 per annum to one of these factories.

LEICESTER, 14th March, 1888.

Wool, Spinning, and Yarn Trades.—There has not been any change of consequence in the wool market since our last report. Values are everywhere depressed; but the country dealers and growers are inclined to reserve their stocks rather than submit to any further reduction. Staplers are neither inclined to buy nor sell, and their dealings are on a limited scale. Spinners have small faith in the firmness of present quotations, and only purchase for their immediate needs. It will thus be seen that the local market for the raw material is in a very languid condition. Very few orders are being booked by spinners. They still have large stocks on hand, as the great bulk of yarn spun lately has been to keep their machinery going. Yarn merchants are not doing a very brisk business, and quotations are rather uncertain.

Boot and Shoe Trade.—This industry received a considerable check from the late severe weather. However, with the return of more genial weather, retail dealers are ordering with more confidence, and wholesale orders which were stopped and delivery delayed are now being proceeded with. It is very likely that there will be a considerable increase of trade between this time and Easter. The turnover of the year has not been quite up to the average.

Hosiery Trade.—Business has been of an unsatisfactory character lately, but at present there is a slightly improved demand for plain hosiery, in cashmeres and cottons. But the heavier woollen department is quiet. Fancy hosiers who produce specialties are fairly busy, and those who do the ordinary trade are tolerably actively employed. Altogether the present condition and the outlook may be considered as encouraging.

BARROW-IN-FURNESS, 14th March, 1888.

Mining Developments.—The demand for hematite iron ore, although very fully maintained, in consequence of the large consumption both in this district and other parts of the country, has not led to any marked increase in price; but as the freights for Spanish ore have increased, a corresponding improvement was shown in local hematite iron ore, and this has led to developments of mining enterprise in various neighbourhoods, with the result that at the present moment the presence of as much iron ore is known of in Furness and Cumberland as at any previous period in the history of the trade. With the view of increasing the output, and extending the working area of the Hodbarrow Mines, at Miltown, the Mining Company there have determined, when the necessary consent of the Board of Trade has been obtained, to build a sea wall at the margin of their royalty, at an estimated cost of £100,000. In the immediate neighbourhood of Hodbarrow there are a few other royalties which have not yet been worked, but which have been proved to be large deposits of exceeding good quality, and which in the early future will be developed, much to the benefit of the district; while from an industrial point of view will afford considerable employment, as well as largely increase the yield of iron ore throughout the district. In other parts of Cumberland, as well as in many parts of Furness, there are also movements being made for the extension of mining operations, which will result ultimately in the working of large deposits of metal which have been proved to exist. The trade in iron ore will depend much on the future of the pig iron trade, but it is satisfactory to note there will be no scarcity in the supply. 8s. 6d. to 11s. 6d. per ton is the present value of ordinary qualities of iron ore.

Iron and Steel.—There is a quiet tone in hematite pig iron, and business has lately been slow. Makers, however, are well sold forward, and have on hand orders which enable them to resist the present low prices at which hematite warrants are changing hands. The business doing in best brands of Bessemer in mixed parcels of Nos. 1, 2, and 3 is at 43s. 6d. to 44s. per ton net f.o.b. Stocks of iron are still very large.

MIDDLESBROUGH, 14th March, 1888.

Pig Iron.—The market is stronger than it has been for some time past, and there is a little more activity. The fluctuations of the Glasgow market generally affect it, but this time it has remained firm. No. 3 G.M. cannot be had under 31s. 6d. per ton on warrants, and makers will not accept that, as they expect better prices presently. Those whose brands have a reputation require a much higher price. In the meantime everything points to an improvement.

Shipments of Pig Iron.—Last month showed a decided increase in the shipments, and this month, so far as it has gone, maintains the improvement. As the navigation becomes more open and the weather more settled it is expected that shipments will be even more favourable. The shipments coastwise account for the bulk of the increase, thus showing that the home consumption is increasing.

Iron and Steel.—The finished iron trade still maintains its activity, and prices are unchanged. The annual report of the Tees Side Iron and Engine Works is typical of the state of trade in the Cleveland district. A profit has been made in the engineering and foundry departments, and a loss on the blast furnaces. Their rolling mills and ship yard are still closed. The entire profit on the year only amounted to £384. 1s. 7d. Bolckow, Vaughan, & Co.'s annual report shows the same hard struggle for a dividend. Workmen ought to see reason in this for very moderate wages if those who find the work are to subsist at all. The latter firm have been fortunate enough to secure an order for 30,000 tons of steel rails and sleepers for the Bengal Nagpur Railway, but it is reported to have been taken at a very low figure, £3. 17s. 6d. per ton is the average price for heavy sections. Steel plates are in as great demand as ever, and maintain their price at £6. 17s. 6d. per ton.

NEWCASTLE, 14th March, 1888.

Rope Works.—Rope manufacturers continue to book new orders, and wire rope for steamers' rigging and other purposes on shipboard are in particularly good demand. Messrs. Haggie Brothers, Gateshead, have some heavy contracts in hand just now for Yorkshire collieries; and the important rope works at Teams, Washington, and Willington Quay are kept extremely busy on orders of a similar kind.

Glass Works.—Brisk business is still the rule at pressed glass establishments, and plate glass works are also well provided with orders. The bottle works at Blaydon show a distinct improvement in the state of business, and at the Gateshead stained glass works the volume of work has also largely increased. The company have just booked an exceptionally large order for glass to be used in the ornamentation of a large hotel at Bournemouth.

Potteries.—In the pottery trade the demand both for home use and export is decidedly good, and as prices show an upward tendency, the outlook for the manufacturers is better than it has been for some time past.

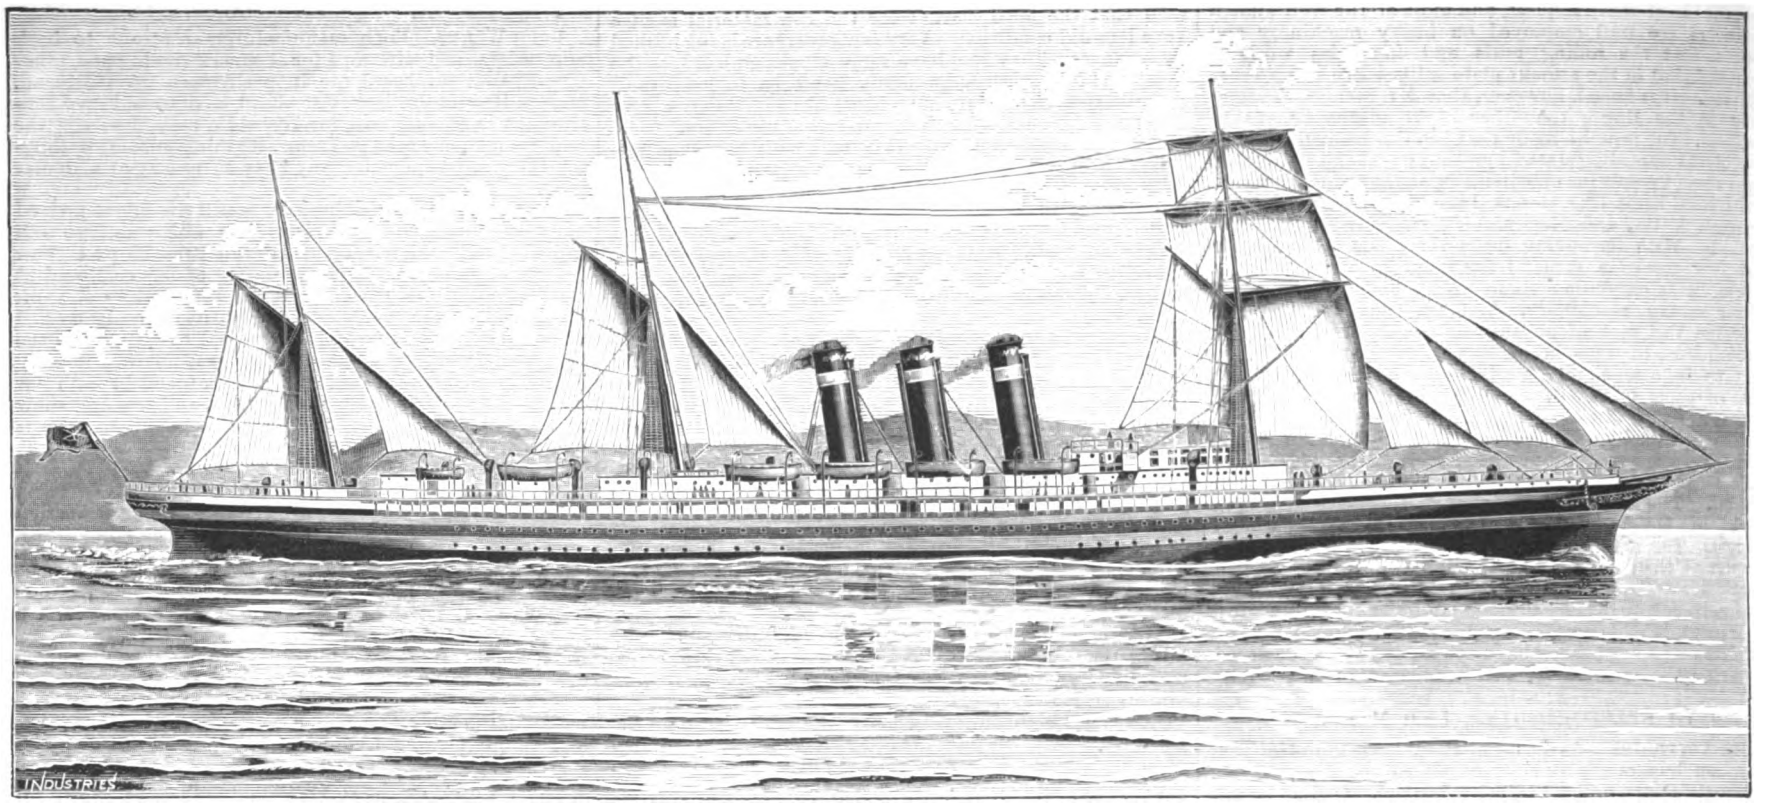
Leather Works.—In the local leather trade there is just now no particular animation, home wants having been to a large extent supplied, and the demand on foreign account, which is chiefly confined to india-rubber goods, having somewhat fallen off of late. The principal india-rubber factory in the district, however, is kept busy on local contracts from engineering firms.

Marble Works.—The marble works of Messrs. Emley and Sons, South Shore Road, Gateshead, keep exceedingly busy, the fitting up of steamers' saloons, &c., constituting a large portion of the work in hand.

Saw Mills.—The increased requirements of shipbuilders have considerably stimulated business in the saw mills, and in most cases the machinery is now kept going regularly.

Engineering.—The engineering establishments are all very fully employed. The most important marine engines at present being fitted are those for the s.s. "Pallas," which are being constructed by Messrs. Raylton, Dixon, and Co. They are triple expansion, of about 3000 i.h.p., fitted up with all the latest improvements, including Weir's feed heater. The boilers are the largest yet constructed by Mr. George Clark, Southwick Engine Works, and are two in number, double ended, with twelve furnaces in all, and working at a pressure of 150lb. per *square inch*. The same engineering establishment has another large vessel, the "Ville de Belfort," awaiting the completion of the engines and boilers. The smaller engineering and boiler making establishments continue to be well employed.

Glass Making.—Although the window glass trade cannot be described as satisfactory, it is encouraging to find that one firm is experiencing a continually increasing demand for lead glazed rolled cathedral tinted glass. The same firm has just secured a large contract for a new wing and other extensions to the local infirmary.



Coal Trade.—Gas coals are in good request, and prices are firm. All kinds of small coals are scarce, and are supplied at increased prices; any further advance will, however, be checked by the substitution of cheap unscreened for small, as low priced coals of the former description are plentiful and of fairly good quality. The demand for coke is good, and prices are steady. The prospects of patent fuel manufacturers continue to be encouraging. The coal shipments of last week show a continued improvement, the total for the week being 88,615 tons, as compared with 81,590 tons in the corresponding week of last year, and 77,500 tons in the previous week of this year; 69,515 tons were shipped coastwise, and 19,100 tons exported. The shipments of coke were 2450 tons, and of patent fuel 1740 tons, as compared with 350 tons and 450 tons respectively for the same period of 1887.

DUNDEE, 14th March, 1888.

Flax and Jute Trades.—The staple industries have undergone little change during the past fortnight. Business in both branches is quiet. The proposed changes in the American tariff, if carried into effect, will greatly benefit the heavier departments of the jute trade, and pending the settlement of the question, dealers are not disposed to enter into important forward contracts. In flax a fair business has been done at extremely low prices. Reports from the different Russian markets are somewhat conflicting, and current prices are difficult to strike. Flax is plentiful, and offers are freely made, but the exchange is uncertain. Flax yarns do not sell so readily as they did a few weeks ago, and prices, if anything, tend in the buyer's favour. In the linen department, manufacturers are well employed. The trade in sailcloth is quiet, but more business is being transacted on account of the makers determining to reduce their prices. The inquiry for all sizes of jute yarns is maintained, and quotations are firm. Buyers of jute goods do not come to terms very readily, and the tone of the market is consequently against sellers. There is a fairly satisfactory business being done in bagging and sacking at full rates; tarpaulin is also being asked for, and is a shade dearer. Manufacturers of jute carpetings are busy, more especially with the finer qualities.

THE S.S. "CITY OF NEW YORK."

COAL, IRON, AND COGNATE INDUSTRIES.

The Board of Trade returns for February show a continued progress in the improvement of our shipping trade, and it is satisfactory to note that in this progress the industries under review have very largely participated. Our total imports for the month amounted to £29,532,776, and our total exports to £18,992,423; being an increase, as compared with the corresponding month of the previous year, of £1,018,782 or 3·6 per cent., and £1,737,290 or 10 per cent. respectively. The total exports of iron and steel for the month amounted to 280,128 tons, being an increase over February, 1887, of 4,851 tons, and over February, 1886, of 54,653 tons. One satisfactory feature of the returns is the increase of our exports of metals to countries other than the United States, *inter alia* the shipments of steel rails to the Argentine Republic and India having conspicuously increased. We have frequently called attention to the prospect of an entire closing of the United States metal market to all but native manufacturers. We append our monthly tabular statement, in a somewhat enlarged form:—

	Month of February.		Period of Two Months.	
	1888.	1887.	1888.	1887.
Pig and puddled	£114,429	£170,681	£226,470	£320,058
Bar, angle, &c.	137,927	98,033	270,610	201,572
Railroad	378,349	209,673	868,838	510,694
Cast and wrought	395,890	281,967	780,620	646,269
Hoops, sheets, &c.	346,114	203,338	619,689	446,258
Steel (unwrought)	109,755	207,960	217,965	334,244
Tin plates	430,782	319,932	820,916	595,647
Unwrought copper	211,894	73,234	433,058	149,551
Coals, &c.	756,505	651,235	1,509,316	1,397,577

Having regard to the above figures, there can be no doubt that our export trade for the first two months of 1888 has comparatively with the previous year been of a highly satisfactory character. The enormous increase in unwrought copper is of course attributable to the enhancement in value of that metal, due to the operations of the syndicate at present controlling the markets of the world. The falling off in our exports of crude iron and unwrought steel, which has been continuous for some months, is a factor which should not be lost sight of by British iron masters. If only our home industries had received a proportionate impetus to that which has left its mark upon the Board of Trade returns, there could remain no scepticism as to a real revival in trade. But unfortunately the reverse is the case. The activity in trade, and the higher prices which were heard of at the close of 1887, have proved but a fitful "flash in the pan," and from many quarters we hear of the same tale of disappointed hopes. Even our most optimist contemporary has at length been compelled to admit that a check has been experienced. Scotch pig iron warrants have reached an abnormally low level; the Middlesbrough market has been flat, and prices of Midland brands of pig have fallen to the lowest point which has yet been touched. In the case of finished iron and steel unremunerative prices prevail, although there exists some feeling of hope that an improvement may be felt in the spring and summer trade. We have frequently pointed out that hitherto prices have advanced at the wrong end, and it is to the finished iron trade we must look for the inception of any improvement which is to be of a permanent character. The continuation of winterly weather through the month of February proved of material value to those collieries producing a coal suitable for domestic consumption. As an index to the increased volume in this branch of trade, we may mention that the quantity of coals supplied by rail to the London market during January and February last reached a total of 1,352,966 tons, as compared with 1,257,410 tons during the corresponding period of 1887, being an increase of 95,556 tons. Prices, unfortunately for colliery proprietors, did not advance, the best kind of screened soft coals being sold in London for 22s. per ton, which, after deducting carriage, terminals, dues, merchant's profits, cost of agents, &c., leaves little more than 9s. as put into truck.

THE "CITY OF NEW YORK."

Yesterday there was launched, on the Clyde, the splendid twin-screw steamship "City of New York," the first of the two liners now being built by Messrs. James and George Thomson for the Inman and International Company. The Inman Company is well known to Atlantic travellers as providing in their floating "Cities" a safe and comfortable means of transit across the Atlantic, and, next to the Cunard, it is the oldest Atlantic steamship company. For some years, however, it retired from the struggle for pre-eminence, at least so far as speed is concerned; but now, after the re-construction of the company about a year ago, under the title of the Inman and International Company, it is coming to the front again by building two splendid steamers with the view of trying conclusions with the present "greyhounds" of the Atlantic. It is expected that the speed of these vessels will be at least as great as the fastest liners now afloat; but at the same time speed is by no means the first consideration which the directors of the company have kept before them, the two paramount considerations being the safety and comfort of the travelling public.

The general appearance of the ships is well indicated by the illustration which we are enabled to give at the head of this page, and which shows to advantage their smart yacht-like form, with three masts and three funnels, which will before long be well known to seamen on the Atlantic. The length of the "City of New York" is 560ft., the breadth 63¼ft., and the depth to upper deck 43¼ft. Above this upper deck, however, is a promenade deck, supported on stanchions, and affording a promenade which is uninterrupted for the whole length of the ship. The most important structural feature in these ships is the thoroughness of the system of water tight subdivision which has been adopted. There are fifteen main water tight compartments separated by steel bulkheads extending from the keel to the upper deck, or to a height of 16ft. above the water line. Two of these compartments could be knocked into one and flooded by the sea without rendering the vessel unseaworthy. Of these fifteen compartments three are devoted to the boilers, which are thus separated into three independent groups. Two other compartments are occupied by the two sets of triple expansion engines, which are also entirely independent, so that if any breakdown were to occur at any time to either of the engines or screw shafts, the ship could still proceed at about three-quarters full speed. The advantages of this duplication of the machinery are so obvious that it is surprising it has not been adopted before this in any of our large Atlantic liners, and there can be little doubt that the Inman and International Company will reap the reward of their enterprise in being the first to provide the additional security of twin screws.

The main saloon is constructed on a principle patented by the builders, which was first carried out in the National liner "America," recently sold to the Italian Government. The central part of the saloon is of a dome-like shape, and rises in a graceful arch to a height of 22ft. above the floor, thus giving an air of spaciousness which has never before been attained on shipboard. The drawing room and library are also spacious apartments, and will be fitted in a style of luxurious comfort. An important feature in these ships is the hydraulic system, which is being fitted by Messrs. Brown & Brothers, of Edinburgh, and which entirely takes the place of steam for such duties as steering, warping, heaving the anchors, loading and unloading cargo, hoisting ashes, &c. The rudder and steering gear is specially designed to be entirely below the water, so as to be efficiently protected in the event of the ships being employed as armed cruisers. The cargo will be worked by twelve hydraulic derricks, which will discharge and take in cargo with great dispatch and an absence of noise, and which will be appreciated by both passengers and officers. From the foregoing description it will be seen that the launch of the "City of New York" marks an important step in the continuous effort to overcome the dangers and discomforts of the stormy Atlantic voyage, and the performances of this new "greyhound" will no doubt create considerable interest during the coming season among all classes of the shipping community.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

FRIDAY, 16TH MARCH, 1888.

MR. GOSCHEN'S CONVERSION SCHEME.

LAST week was notably a financial week; announcements of the Navy Estimates, of the Army Estimates, and of the Conversion Scheme of Mr. Goschen, followed in almost bewilderingly rapid succession. The first Budget of Mr. Goschen so far infringed the canons of sound finance, that in spite of its offering a bold bid for popularity in the shape of a reduction of taxation, it fell short of any but qualified approval. It was thus necessary for him, in his financial proposals for the present year, to rehabilitate his reputation. Yet, in doing so, it would seem as though he had simply developed the policy which he adopted in his Budget last year. Then, it will be remembered, he deducted a sum of £2,000,000 from the amount set aside for the charge of the public debt, thereby reducing the amount which would have been available for redemption, from £7,000,000 to £5,000,000. This latter amount, however, Mr. Goschen intimated would suffice to redeem the whole present debt at par in fifty-seven years. The policy of reducing the annual charge for the National Debt has been again followed by Mr. Goschen; but instead of cutting off a portion of the Sinking Fund as formerly, he has adopted the sounder plan of reducing the rate of interest. Mr. Goschen's scheme involves, therefore, so far as appears at present, not any alteration in existing arrangements for the reduction of the principal sum, nor does it involve any addition to the principal sum; it produces alone the saving of ¼ per cent. in the interest of a portion of the debt for fourteen years, and a further saving of ¼ per cent. in the interest for a further period of twenty years. Since a part of the reduction does not come into practical operation until next financial year, there will not be any serious disturbance of the coming Budget; but the result will be that for thirty-five years we guarantee an interest of 2¾ to 2½ per cent. upon the stock proposed to be dealt with. The stock which the Conversion Scheme proposes to deal with primarily is the New Three per Cents, amounting at present to £166,000,000, and redeemable now at the pleasure of the Government. The reduction of interest upon this stock will effect an annual saving of £410,000 a year, from the beginning of the ensuing financial year, and a further saving of a similar amount from April, 1903. These sums represent the successive deductions of ¼ per cent., by which it is proposed to effect automatic reduction from 3 per cent. to 2½ per cent. But the complete proposal of Mr. Goschen involves much more extensive operations. In addition to the New Three per Cents, the bulk of the stock of the National Debt consists of £69,000,000 of stock known as Reduced Three per Cents, and £323,000,000 of Consols, also 3 per cent. These stocks are upon a different footing from the Threes. They are only redeemable at par upon a year's notice. In order to effect an immediate arrangement with these stock holders, Mr. Goschen proposes to allow them in cash, upon conversion, the ¼ per cent. to which they are entitled for the year in lieu of notice. Instead, therefore, of their receiving half yearly their 3 per cent., they will receive at once ¼ per cent. on condition of their stock being converted at par into the new Consols, bearing a dividend of 2¾ per cent. Should the conversion be carried completely into effect, there will be an immediate saving of £1,400,000, and an ultimate saving of £2,800,000 per annum. Mr. Goschen has adopted a method for which he advanced several precedents—that is, the method of regarding silence as consent; but he improves on the lesson of his predecessors by giving the national creditors very little time to reflect. To hesitate is to be lost. Fund holders must dissent before the 29th inst. against the conversion of the New Three per Cents, or if they are holders of Consols, or Reduced, they must apply for their ¼ per cent. before the 12th April. Mr. Goschen thus minimises as much as possible the time during which extraneous influences, such as European complications, could militate against the success of his scheme, and also sharply brings the fund holders to the point. As to his legal right to effect this transformation of the debt there can be no question, nor indeed can there be any question of its advisability from the point of view of national economy; the only question is, can he do it? Is there not a possibility of the fund holders refusing to convert, and of the Exchequer being unable to raise funds sufficient to pay them off at par. Mr. Goschen has expressed himself as extremely confident on this point. So sure is he that he said: "I say, weighing every word, that I have no fear of the success of my plan." There are indeed many reasons why he should succeed. The rate of interest on first class securities has been steadily tending downwards for several years. The price of Consols has been steadily going upwards; the rate of interest on good foreign loans has been subject to successive reductions during recent years; money is therefore so cheap that there is much force in Mr. Goschen's argument that the fund holders must take 2¾ per cent., for the best of all reasons, because they cannot do better. On the other hand, there is much of the wisdom of the serpent in Mr. Goschen's precipitancy. Trade is apparently reviving; with returning energy of demand there will come the floating of new industrial enterprises and the expansion of old; increased industry will demand increased capital, and money may ere long come to be dearer. All the more reason for the stock holder to reflect, and still more reason for Mr. Goschen to act promptly. The Chancellor of the Exchequer really possesses considerable powers of coercion. He can borrow, and does borrow, on Exchequer Bills at £1. 12s. 6d. per cent., and the amount which in case of need he might put upon the market is indefinite. Should he elect to perform a risky operation, he might transform temporarily a portion of the funded debt into floating debt in the anticipation that sooner or later the money holders would have to come to his terms. But such a financial expedient is really not necessary. Though a considerable number of dissentients would paralyse the scheme, they could not disturb either the national credit or the Exchequer, it would only postpone the complete realisation of the scheme of Conversion. There is another point; considerably over a hundred millions, spread over all the stocks, are held by the Government on behalf of State departments. That is to say, that of the seven hundred millions of which the debt is composed, only about six hundred are in the hands of the public. This means of course that the National Debt Commissioners have credit to borrow a hundred millions more than the present net debt. With the aid of the downward pressure of the money market,

Digitized by Google

which so far cannot be said to have suffered serious check, and the strong financial reserve forces at the disposal of the Government, there can be little doubt that Mr. Goschen's scheme will secure a large measure of success. The likelihood of such a scheme being carried out at some time has long been present in the minds of financiers, so that the Conversion does not as a matter of fact disturb any financial calculations of moment, and is quite unlikely to cause any monetary dislocation whatever, while a relief, prospective though it is, of from £1,500,000 to nearly £3,000,000 a year to the overburdened tax payer, is to be cordially welcomed. Should the accumulation of capital go on during the next twenty years at a rate equal to the accumulations of the past twenty, the Chancellor of the Exchequer of the day may find himself in a position to test the truth of the adage, "John Bull can stand many things, but he cannot stand 2 per cent." While Mr. Goschen must be congratulated upon having apparently effected a considerable lightening of the burden of the public debt, there are incipient dangers in the policy he has consistently adopted in both his Budgets. A financially strong Government has two ways of dealing with its debt; it may devote itself to the reduction of the charge for the service of the debt to the lowest possible annual sum, or it may retain a high annual charge, paying the lowest interest and utilising the balance in redemption of debt. Mr. Goschen seems inclined to adopt the first method, which, rigidly adhered to, would have the effect of leaving the principal of the debt as it is, though reducing the burden of it. The second method is that which was followed by Mr. Gladstone and Sir Stafford Northcote during their periods of office at the Exchequer. From the banker's point of view, Mr. Goschen's plan is certainly the most convenient. They naturally desire a large homogeneous stock perfectly safe, which they may buy and sell at any moment, which is tolerably steady in price, and at the same time sufficiently susceptible to general financial movements to move upwards and downwards with other first class securities. It is essential for the banker that he should have his own money and that of his depositors invested promptly and promptly realisable. And this object the National Debt clearly enables him to obtain. The paying off of our National Debt would unquestionably result in a general rise in price of all first class securities—municipal stock and Foreign State loans especially. The general rise during the past ten years of our own stock, and that of many foreign nations, in first class credit, has among other causes undoubtedly been due to the encashment of the American Debt. This encashment has restricted the area of first class security, and thus raised the value of the restricted area. Although the interests of the bankers are not always the same as, and are often even opposed to, the public interest, the stability of commerce depends very largely upon the stability of banking arrangements. It is of little public importance whether this or that bank pays a dividend; but the stability of banking in general is important, and this depends largely upon the facility with which bankers obtain a moderate interest upon perfectly sound investments. The restriction of the area of first class security might have the effect of driving bankers to inferior securities merely that their money might be utilised. It is, therefore, a question of a balance of advantages. Is it better for the country to pay a tax of some £26,000,000 a year as an insurance for commercial stability, or to pay off the debt and allow commercial stabilty to look after itself? This has been done in America, and not with wholly satisfactory results, though these results are influenced by the unfortunately restricted terms upon which the American Debt was borrowed. The debt was contracted in great emergency, and now, though the Treasury could pay it off in a very few years, it is hampered in doing so by the periods for which the money was borrowed. The question arises in regard to Mr. Goschen's scheme: Does the automatic arrangement by which the interest is guaranteed at 2¾ per cent. for fourteen years, and at 2½ per cent. for twenty years, not afford the presumption that the new 2½ per cent. stock thus created is irredeemable until thirty-five years from now, or till 1923? If this is so, though it may present inducements now to the fund holder to convert his redeemable stock into irredeemable, it may carry with it the germs of future trouble. Who can predict the rate of interest at which money might be borrowed thirty-five years hence? Upon this point it would be well to have illumination, and also upon the method which Mr. Goschen proposes adopting in dealing with the Sinking Funds. Does he desire to keep the capital sum of the debt as it is, or is he prepared to advocate its rapid reduction?

THE FORTIFICATION OF OUR PORTS.

A few weeks ago we directed the attention of our readers to an address by Lord Brassey on the protection of trade, with reference to the defence of our foreign stations (see Vol. IV., page 142). The report of a committee appointed by the Secretary of State for War to consider with him the plans proposed for the fortification and armament of our military and home mercantile ports, and the relative importance and approximate cost of the works and armaments necessary for the adequate defence of these stations, has been recently issued, and a short notice of it will form a suitable supplement to that on Lord Brassey's address. We need not enter into the financial details included in the report, but will briefly note a few of the general arrangements which the Committee consider necessary.

The revision of armaments proposed for the military ports has, in each case, been worked out in detail by the Royal Artillery and Royal Engineers' Works Committee. The plans for the defence of the mercantile ports were originally projected in 1882, but considerable alterations have since been made in the proposals, and even now they have not been worked out in the same detail as in the case of the military ports. The Committee examined a considerable number of witnesses, including many of the most eminent naval and military authorities, and these were unanimous in pointing out the weakness of our present position, and in urging the imperative necessity of strengthening and adding to the existing defences, though with some natural divergence of opinion on minor questions. The Committee carefully considered all the circumstances connected with the defence of ports, and especially how far the co-operation of the fleet diminishes the necessity for fortifications, and they obtained in each case full information as to the facilities for submarine mining and for active torpedo defence, and they took into account all these when making their recommendations. These are divided into two parts, the first relating to military, and the second to commercial ports.

Among the so-called military ports three at once suggest themselves as far exceeding all others in importance. They are Portsmouth, Plymouth, and the ports included within the Thames and Medway defences. The Committee are of opinion that it is not too much to say that the destruction of our great dockyard at Portsmouth—and in a less degree of that of Plymouth—might be decisive of the issue of a great war; while the defence of the Thames and Medway is likewise of paramount importance, not only because in these rivers are situated the yards of Chatham, Sheerness, and Woolwich, but also because it is almost universally believed that an enemy descending upon England would immediately endeavour to strike a blow at London. If the Thames and Medway are not adequately defended facilities are afforded for such an enterprise, while Harwich also deserves very special attention as a possible base of operations for a sudden attack upon London. After carefully inquiring into the condition of each of these ports, the Committee have no hesitation in stating their conviction that deficiencies exist in the defences of each of them, which render our position dangerously insecure. The present defences although sufficient for their protection at the time they were erected are now insufficient, and the enormously increased range and penetration of modern guns, and the great strength of iron clads, now render partial—and in some cases very extensive—re-construction essential, and necessitate an armament equal to modern requirements. The Committee place as next in importance the defence of Malta and Gibraltar, as upon the maintenance of these two fortresses depends our position in the Mediterranean; and here too we must be prepared to face a possible attack of heavy ironclads, combined in the case of Malta with the attempt to land a large force. Both require very considerable additions and alterations of armament. The Committee have also considered the cases of Bermuda, Halifax, Cork, Pembroke, Portland, and Dover. The report being intended for publication, it has not been deemed prudent to enter into details of the deficiencies, or give descriptions of the works which are proposed for the purpose of making these good. The Committee, however, state that to carry out the works which they have suggested as urgent will involve an expenditure of not less than a million and a half; and they recommend that as little delay as possible should be allowed to intervene before commencing works, some of which, it must be remembered, will necessarily take a considerable time to complete.

With regard to the mercantile ports, beyond a small expenditure for surveys on the Tyne, and for submarine mining works at almost all the ports, no commencement has yet been made in works for defending these ports. The evidence given before the Committee disclosed a great variety of opinion as to the objects to be arrived at, and the extent to which they can be attained. The following, however, is a summary of the general conclusions at which the Committee have arrived: (1) If a defence is adopted for these ports sufficient to repel the kind of attack which, according to the evidence, is most to be apprehended—viz., that by armoured cruisers—and if it be adequately supplemented, according to the necessities of each case, by submarine mines or torpedo boats, the Committee are of opinion that these ports may be regarded as reasonably safe. The special importance of the Clyde, the Tyne, and the Mersey may, however, necessitate in these cases the addition of a heavier armament. (2) The danger most to be guarded against is not so much an attack on the ports themselves, as on the commerce converging upon them. (3) It is impossible to give absolute protection from bombardment to towns lying upon the seaboard, as the long range of existing guns will enable a comparatively small ship, at a distance of four or five miles, to bombard a town. (4) In some of these cases an active naval defence is the only one which can adequately protect the port. (5) Where mercantile ports are situated at some distance up a river, submarine mining defence will in general afford a very great protection. The Committee think it essential that, wherever this is adopted, the mine fields should be protected by quick-firing guns. They further give suggestions for a combination of the efforts of the local authorities with the regular forces of the army and navy, and they state that the evidence before them points unmistakeably to the necessity of an increase in (1) our regular Garrison Artillery, especially for colonial ports, (2) our Fortress Engineers, and (3) our Volunteer Artillery and Submarine Miners, according to the necessities of each port. The first two additions require further provision out of public funds; but the last, which for our home ports is the most essential of all, ought to be mainly produced by local effort. The Committee, therefore, cordially endorse the action which is now being taken by the War Office to encourage each port to be ready to meet, by voluntary effort, the special requirements for its own protection.

UNDERGROUND ELECTRIC LIGHT WIRES.

It will hardly be disputed that English engineers and electricians have yet a good deal to learn in the matter of distributing electricity, whether by overhead or underground mains; but the lesson taught them by Mr. W. Leggett, in our contemporary the New York *Electrical World*, will hardly prove a palatable one. This author, after briefly reviewing the first examples of underground electric conductors, which date back to 1816, refers to the great difference which exists between the mains used for direct incandescent supply and the cables used for arc lighting. Whereas, after some little trouble, it was found perfectly feasible in American towns to supply thousands of glow lamps by means of underground mains, all attempts to supply arc lights by underground cables have, according to Mr. Leggett, hitherto failed. The reason of failure is attributed primarily to the difficulty of insulating cables laid underground. Even if a large subway were constructed, and the cables were trained on insulators very much in the same manner as is now done overhead, Mr. Leggett thinks the leakage would be excessive, the reason being that the air in an underground conduit is necessarily moist. Moreover, very few localities could afford the expense of an underground subway large enough for this purpose. The estimated expense of such a subway 4ft. wide by 8ft. high for Chestnut-street, in Philadelphia, alone, is no less than £300,000, and the maintenance would also be considerable, because it would be necessary to supply the subway with forced ventilation. Owing to this almost prohibitive cost, American companies have universally adopted some sort of conduit system other than that of a subway, but with uniformly discouraging results. The Board of Commissioners of Electrical Surveys, at Brooklyn, after investigating the subject for a considerable time, came to the conclusion that: "With regard to electric light conductors this Board has found no device which would with certainty, in its opinion, enable the wires carrying arc light currents

Digitized by Google

to be safely and successfully operated in the same conduit with telephone and telegraph conductors without disturbance or injury to the latter." In a later report, dated 15th December, 1887, they stated that the subject of underground conduits for arc currents is the one which presents the most numerous and novel difficulties. Mr. Leggett, after quoting further statements of this Board, gives a long list of cases in which arc light cables had been laid underground, and had within a short time either to be repaired or entirely taken up. The best results seem to have been obtained with lead covered cables, but if these were used in conduits where creosote was employed the effect was to oxidise the lead and destroy its protective property. It was also found that illuminating gas could not be kept from the conduits, and many explosions occurred from this cause. The reason of the failure is attributed to the high pressure employed on arc light circuits in America, the pressure seldom being under 2000 volts, but in many cases it reaches 3000 volts; whilst on the alternating current system, on which lead covered cables have hitherto proved least troublesome, the pressure carried is only about 1000 volts. The practical conclusion of Mr. Leggett's article is that corporations and town authorities should not insist upon electric arc light companies undergrounding their cables, as by doing so they ask the companies to perform what may almost be considered an impossibility in the present state of our knowledge. The picture painted by Mr. Leggett is exceedingly sombre, and we doubt very much whether, had the work been done in England, the results would have been the same. Excepting the experiments made with cables on a limited scale at Eastbourne and some other places, very little has been done in this direction on our side of the Atlantic, and it would be well to take notice of these failures. We trust that by having drawn attention to the matter, some of our electrical engineers may be induced to work out a system of underground high pressure distribution which will be free from the defects attributed to the various schemes which have been tried in America.

Letters to the Editor.

PROPOSED LEGISLATION FOR THE COMPULSORY INSPECTION OF STEAM BOILERS.

To the Editor of "Industries."

Sir,—My previous letters, which you have been good enough to publish, have been devoted to showing what the present Board of Trade inspection of steam boilers is like, and in so doing I have made the Assistant Secretary, Engineer Surveyor in Chief, and the Engineer Inspectors speak—as I have simply quoted their words verbatim. In so doing, I may now ask, have they shown themselves to have that grasp of the subject, or that competency which should cause us to hasten to entrust the care of all the boilers in the kingdom to them? Does any steam user feel satisfied that his interests would be served, or that any commensurate benefit would accrue from the enormous trouble and expense which would thereby be incurred?

Some of your correspondents, many of the public, and some writers for the press—whose opinions are formed upon what is popularly and generally known of the operations of the boiler insurance and inspecting societies—think that the passing of a Bill for the compulsory inspection of steam boilers, provided it could be carried out on similar lines, would be both feasible and beneficial. The scheme proposed by the Board of Trade of absorbing the existing associations and using them as delegate societies, and of deputing, for some time at least, its powers to them, has led to totally false and incorrect impressions of its real aims and objects being taken and held by a considerable number of those who have not examined and considered the provisions of the proposed Bill for themselves.

In order that something like a correct impression of the intentions of the Board of Trade may be formed, and of what inspection under the proposed Bill would be like, let us examine the Bill itself, and we shall find that under Section XIV., clause 1, it is provided that "if on complaint or otherwise the Board of Trade have reason to believe that any boiler is unfit for use, they may require the boiler to be surveyed by an inspector." Again in clause 2: "For the purposes of this section every inspector shall have all the powers conferred on the Court named in Section VI. of the Boiler Explosions Act, 1882, and any person who obstructs an inspector in the performance of his duties under this section shall be liable to the penalties imposed by that section for obstruction."

Upon referring to Section VI. of the Boiler Explosions Act, 1882, we find that the powers of the inspector will be those of a Court, as defined in the words of the Act—Section VI., clause 4: "The Court [inspector] shall have, for the purpose of 'its' [his] investigations, all the powers of a Court of Summary Jurisdiction then acting as a Court in the exercise of its ordinary jurisdiction, and shall, in addition, have the following power, viz.: (*a*) The Court [inspector], or any one appointed by it [him] may enter and inspect any place or building, the entry or inspection whereof appears to the Court [inspector] requisite for the said purpose. (*b*) It [he] may by summons under its [his] hand require the attendance of all such persons as it [he] thinks fit to call before it [him] and examine for the said purpose, and may for such purpose require answers or returns to such inquiries as it [he] thinks fit to make. (*c*) It [he] may require and enforce the production of all books, papers, and documents which it [he] considers important for the said purpose. (*d*) It [he] may administer an oath, and require any person examined to make and sign a declaration of the truth of the statements made by him on his examination." We have now before us, accurately defined, the proposed powers of the future Board of Trade engineer inspector, which will, no doubt, astonish the steam user who now becomes acquainted with them for the first time.

Let us ascertain where these tremendous and arbitary powers come into force, and under what conditions the unfortunate steam user may become subject to them. The proposed Bill states, in clause 14, "that if on complaint or otherwise the Board of Trade have reason to believe that any boiler is unfit for use, they may require the boiler to be surveyed by an inspector." From which it is evident that from an information lodged by a neighbour as to the condition of the boiler, which might be most unfounded or even malicious, an inspector with "the powers of a Court" would be sent to stop the working of the boiler, no matter what inconvenience or loss might be caused by the enforced stoppage, to inspect, examine persons, books, papers, documents, administer oaths, and possibly cause stoppage of the works for days. Again, in clause 6 of the proposed Bill, it is provided that "it shall not be lawful to use any boiler to which this Act applies unless it has been surveyed, and a certificate for it issued, as provided in this Act, is in force. The certificate shall state the period during which the *boiler may be safely used*, and shall cease to be in force at the end of that period or any earlier date at which it is cancelled under this Act."

From these clauses it is clear that upon the expiration of the certificate stating "the period during which the boiler may be safely used," a boiler would become unsafe in the eyes of the Board of Trade until the owner was again provided with a certificate. It follows, therefore, that these tremendous powers of the engineer inspector come into force, firstly, upon any complaint as to the condition of a boiler; and, secondly, whenever a boiler can be found that it is not certificated safe by the Board of Trade engineer inspector. Consequently, every owner of a steam boiler would on any of these occasions be open to the visit of an engineer inspector, provided with "all the powers of a Court of Summary Jurisdiction, when acting as a Court in the exercise of its ordinary jurisdiction, and shall have in addition" the powers already explained under clauses *a*, *b*, *c*, and *d*.

The certificates are only intended to be available for twelve months, and therefore at least once a year the steam user will be liable to the visit of an inspector with "the powers of a Court." Those firms who already have their boilers under periodical inspection know how difficult it is at all times to arrange their business so that their boilers may be thoroughly examined within each twelve months; and find it sufficiently irksome and inconvenient to stop their boilers when required by the inspecting companies having charge of their boilers. Under Government inspection convenience must be set aside, a certificate must be had and produced when required; boilers must be stopped, examined, and certified—that is, if the inspector is satisfied.

With the extremely peculiar views entertained by the Board of Trade as to the strength and safety of boilers, and their numberless deductions of percentage in strength, according to any slight deviations that may be found from their approved standard, it would certainly be curious to inquire how long a boiler would be allowed to work at the pressure for which it was originally intended and made. How long would it be allowed to work without being tested by hydraulic pressure? How often would it require to be entirely stripped of brick work and re-seated? Boilers in possession of the Government are, it is generally understood, tested by water pressure after every five hundred hours' working. Here is a standard! How would steam users relish testing every boiler once in each five hundred hours of working? Under such inspection the principal business of a steam user's life would appear to be looking after his boiler, being examined—on oath—by the inspector, producing books, papers, documents, and superintend the attendance of his workmen upon the inspector—a pleasant prospect! Take a case of a steam user in the midst of an important time contract, when the stoppage of his works for even an hour would be of the most serious consequence, finding that the certificate of the safety of his boiler had just expired down comes the inspector, Government and the Board of Trade must not be trifled with, certificate must be produced, otherwise work must be stopped instantly, and if any defect caught the inspector's attention, suspended until remedied. Complaint has sometimes been made as to the manner and bearing of the inspectors of the inspecting societies, and feelings of irritation expressed at the presumed dictatorial and too confidently expressed opinions given by their engineers, probably arising from a very great special experience, which causes them to take contradiction from imperfectly and often incorrectly informed sources, with some little impatience. But this can be remedied at the renewal of any policy by simply ceasing to pay the premium and severing the connection. The inspectors of the boiler insurance companies are practically servants of the insured, and can be dismissed at will; but what would be the manner and bearing of these very men, if they were upon any premises with the authority of the Board of Trade behind them, and "the powers of a Court with Summary Jurisdiction" in their hands and mouths?

Steam users would then find relations reversed, and the inspector the master certainly of the situation for the time being; and if complaint is now made, and irritation and annoyance felt, what would be the condition of affairs under the changed relations? Is it too much to say that such a condition of things could only possibly exist for a short term, as the strain would be too great to be borne, and the indignant body of steam users would rise and sweep the whole irritating, unnecessary, and wholly uncalled for fabric of rules, regulations, and restrictions away? The Englishman of to-day is a tame dog, and under the worst provocation only snaps and growls; but the engineer inspector might, it is thought, provoke him to bite.

Since my last letter, Mr. Provand has brought into the House of Commons a Bill to amend the law relating to and providing for the compulsory examination of steam boilers. Lord Stanley, who had charge of the Boiler Registry and Inspection of Boilers Bill in the House of Lords, has been moved from the Presidency of the Board of Trade to the Governor-Generalship of Canada. What effect this change may have upon the latter Bill, it is of course impossible to accurately predicate; it is possible, however, that Sir Michael Hicks-Beach, his successor, may not be so easily convinced of the necessity for such a piece of meddling, useless, and mischievous legislation, and consequently it may possibly be allowed to drop quietly out of sight for a time, until revived again at some more favourable juncture. Mr. Provand's Bill now will come before us, and its provisions will be looked forward to with anxiety. It is, however, of the greatest importance for steam users to clearly see and feel their position in the event of compulsory inspection being pressed forward, whether by Mr. Provand or the Board of Trade.

Once more let me repeat that no further legislation is required, the Boiler Explosions Act, 1882, is ample in its powers for all necessary purposes, and if its powers were put in force the numbers of explosions would be reduced to the lowest possible number. Let the whole of its provisions be put in force, and the Act tried for another term of years, and then if the results do not justify the course taken let further legislation be made; but when we find that the fear of an inquiry only—although it is clearly understood that no pecuniary or other loss is likely to accrue—is sufficient in four years to reduce the number of explosions 42 per cent., the result may be easily foretold.

When once steam users are properly informed on this subject of compulsory inspection, and grasp the results that will flow from their being subjected to it, their decision will be sharp, clear, and decisive. Even if during a period of indifference and inactivity such a measure is allowed to slip through Parliament, steam users will, under governmental treatment, soon recover from their somnolence and lassitude, and find energy to erase it from our statute book; but in the meantime what annoyance, what trouble, what loss, and what a great and serious check to industrial progress will have been suffered.

Yours, &c.,
Economiser.

Manchester, 10th March, 1888.

To the Editor of "Industries."

Sir,—Your correspondent "Economiser," who writes so intolerantly on the boiler inspection question, still appears to be quite ignorant of the fact that in discussions personalities are not arguments, and I again decline to be led away by his example, although, were I so minded, it would be impossible, as he has taken the convenient but unsatisfactory precaution of shielding himself under an anonymous signature.

For reasons best known to himself, your correspondent appears to have set me up as an advocate of Board of Trade inspection. I again repeat I am nothing of the kind. I simply believe that it would be a good thing if all steam boilers were periodically inspected, and as some owners, either through carelessness, poverty, or avarice, let their boilers work for many months, or even years, without any adequate examination, the only way to reach them is to make inspection compulsory. I do not care in the least who the inspection is made by if it is properly done, and the liberty of the boiler owner is not interfered with.

In quoting from the *Engineer*, your correspondent takes a solitary sentence and adapts it to his own use. I said the article in question corroborated my statement, that many worn out boilers are in use, and this I still maintain. Notwithstanding the Report of the Assistant Secretary of the Board of Trade—which I conclude your correspondent quotes, as it happens in this case to suit his own ideas—I am yet to be convinced that it would not be a gain to all concerned if only properly qualified men could be entrusted with the care of steam boilers; and I agree with the remark of "A. C." in your last issue, that "it would harm no one, would add to the longevity of the boiler, lessen the coal bill, increase public safety, and improve the status of the men." Notwithstanding the assertions of "Economiser" that "experts"—an unknown quantity—consider this idea an exploded one, how comes it that a Scottish boiler association is now initiating this very system of certificates? If your correspondent will take the trouble to look carefully through the columns of your contemporary of the issue I mentioned, he will find on page 150 an important communication on this very subject, in which the granting of certificates to boiler attendants is strongly urged. If the proposed Bill be bad in every respect, as your correspondent would wish us to believe, how comes it that the Blackburn Chamber of Commerce has declared in favour of it with some modification of clause 10? and how will he account for the action taken by the Associated Chambers of Commerce, as shown by the following newspaper report:—

"The third and concluding meeting of the annual session of the Associated Chambers of Commerce was held at the Hotel Metropole, on Thursday, the 23rd ult., Sir Bernhard Samuelson, M.P., presiding. The following resolution had been placed on the paper by the Oldham Chamber:

'That this Association is strongly opposed to the Boiler Registry and Inspection Bill, 1887 (introduced into the House of Lords by the President of the Board of Trade last session), which they consider unnecessary, as shown by the rapid diminution of accidents which have taken place during the past few years, and as only likely to further embarrass trade, already sufficiently harassed by Parliamentary enactments, and would call attention to the Boiler Explosions Act, 1882, the powers under which already conferred upon the Board of Trade, if put in force, are amply sufficient to act as a safeguard against accidents, and as a deterrent to carelessness on the part of owners of boilers.'

"This was strongly opposed, and eventually negatived in favour of an amendment to the effect that the meeting, without pledging itself to all the details, approved the principle of the measure referred to, as the Act of 1882 had not been a sufficient safeguard against avoidable accidents."

Yours, &c.,
M. Powis Bale.

London, E.C., March 12th, 1888.

Stoppage of Abercarn Tin Works.—A notice was posted on the 10th inst., at the Abercarn Tin Plate Works, intimating that the works (with the exception of a water mill) would remain closed until further notice. The works have been kept going on day to day contracts for some time. Hence only twelve hours' notice to cease work was required.

THE NEW EXPLOSIVE "HELLHOFFITE."

The safe working of mineral property has for nearly twenty years been an anxious care to the Legislature, to specialists, and to the general public in this country, and at present there still remain unsolved two mining problems of the greatest importance. A perfectly efficient and safe miner's lamp has yet to be provided, and colliery managers are still far from unanimous in their approval of an effective and at the same time harmless substitute for gunpowder and dynamite as explosive forces. The lamp question has continuously been the object of scientific application, but it is only recently that inventive genius has engaged itself in the task of modifying the process of breaking down minerals by means of dangerous explosives. Progress in this work has been marked by the water cartridge, gelatinous cartridge, securite, tonite, a variety of mechanical coal getters, and other more or less practically useful productions. "Hellhoffite," which is one of the latest additions to the list, hails from the Continent, and is said to be a harmless explosive. Hellhoffite is a red and rather caustic liquid, and is formed by a combination of the nitro-products of tar oils with nitric acid. It may also be obtained as a solid, this state being arrived at through absorption of the liquid by "kieselguhr"—fossil earth.

The cartridges which contain the explosive are made, for light charges, of refined lead, and these may be driven into the blast holes under pressure, are capable of filling up unevenly drilled holes, and can sustain deformations without their contents being affected. The explosive is fired by means of strong caps, primed with fulminate of mercury, inserted into small lead tubes tightly screwed in the cartridges, and these need not be fitted on until just before firing. Numerous experiments have been made at various Continental mining centres under diverse conditions with this explosive, and have uniformly resulted in a clear demonstration of the great force it exerts, and of the perfect safety with which it may be used. From a tabulated statement contained in the final report of the Prussian Royal Commission on explosions in mines, it appears that a long series of experiments with hellhoffite were conducted in the drift of a mine, where in each case the percentage of fire damp varied. In one instance it amounted to 10 per cent., and when coal dust as fine as flour was strewed for a distance of 10m., no flame whatever appeared. According to the same authority, liquid hellhoffite is 70 per cent. more powerful than guhr-dynamite, and 30 per cent. more than liquid nitroglycerine; and in the opinion of the Imperial and Royal Mining Department of Pribram, it has over 38 per cent. more breaking power than Nobel's gelatine dynamite No. 1. The following is culled from an official report of the Royal Hungarian Mining Department of Schemnitz:—"A rail of the narrow gauge Schemnitz line was laid free upon a grass plot, and a 100-gramme hellhoffite cartridge so placed upon the rail—totally uncovered—as to be located between flange and foot. The cartridge being fired by an electric fuse, the whole foot of the rail was torn away for a length of 15cm., and hurled to a distance of over 50m., the surfaces of the fragments showing initial signs of fusion. A 105-gramme dynamite cartridge, placed in the same manner upon a similar rail, exploded when fired without showing any vestige of destruction." When we add that the products of combustion remaining after the explosion of the hellhoffite are only characterised by the smell of the burnt fuse, and are neither dangerous nor disagreeable; that the price of this explosive, including the filling of the cartridges and the packing, is less than that of dynamite; and that when used in a pit the tendency of its breaking power is rather to rift than to shatter, it is sufficiently clear that the explosive to which we now direct attention is one which will make its influence felt in the mining world.

ALLOYS AND THEIR PROPERTIES.

The first of a series of three lectures on "Alloys," was delivered by Professor Chandler Roberts-Austen, F.R.S., of the Mint, at the Society of Arts' Rooms, on Monday last. The lecture was devoted, for the most part, to a retrospective glance of the work which has been done in the past by the alchemist, and drew attention to the difference which exists between the ancient and modern uses of metals. Antimony was commonly employed by the Greeks in the arts, but now this metal is only used in alloys with other metals. There are very few chemical notices of the composition of the alloys used in earlier times; but we find in the writings of Reaumer, Gillert, Muschenbrock, and Achard several allusions to the mixing and making of metallic mixtures. Reaumer propounded a theory in which the hardening of steel was explained by the sulphur and salts, which he supposed existed between the molecules of the metal, not having had time enough to be taken up by the metal when it was suddenly cooled. Achard drew attention to the similarity in behaviour of the metals towards heat, and electricity. Matthiessen in 1860, from an examination of the electrical resistance of the metals when pure and when alloyed with one another, came to the conclusion that alloys contained the metals in an allotropic condition, or in such a form as to be practically different from those used in preparing the alloy. There are three methods of general use employed for making alloys, viz.: (1) Fusion; (2) pressure; (3) electro-deposition. It is very essential that the metals used should themselves be as pure as possible, as traces of foreign metals present considerably modify the properties of the alloys. Tin, for example, is a soft and ductile metal; but when it contains a trace of arsenic it becomes brittle, or if there is a larger quantity of arsenic present it forms a crystalline mass resembling zinc. With a drop of mercury the tin becomes so brittle that it can be readily broken by the fingers. Alloys may be divided into two classes, according as heat is evolved or absorbed in their formation. The alloys of aluminum and copper, lead and tin, gold and tin, arsenic and antimony, and bismuth and lead, are all formed with the evolution of a considerable quantity of heat; while an alloy of tin, bismuth, and lead in equivalent proportions, when mixed with mercury so as to form an amalgam, absorbs heat to such an extent that it may be used to freeze water. When the metals are alloyed together, first by fusion, and then powdered and mixed with mercury, the cold produced is not so great as when the powdered, unalloyed metals are rubbed with the mercury. The formation of alloys by pressure was first studied by M. Walter Spring. He found that powdered metals, when welded together by simple pressure, became converted into a compact mass; and if the pressure was still further increased, the alloy formed flowed into the crevices of the mould. Powdered lead, under a pressure of 13 tons per square inch, becomes a compact lump, and under a pressure of 33 tons per square inch becomes fluid, and flows into the interstices of the machine.

Similar phenomena are observed in the case of tin when subjected to great pressure. Alloys can be produced in the same way; powdered bismuth, lead, and tin, when mixed in suitable proportions and compressed, form an alloy which melts at a lower melting point than that of the most fusible metal of the three. No heat is experienced when pressure is applied in this way, as the compression is allowed to take place very gradually. Some alloys of metals are known which only exist in the liquid state, so that on cooling the homogeneous liquid separates the metals contained in it in a more or less pure condition Lead and zinc form a solution which almost entirely separates its metals on cooling. A mixture of copper, antimony, and lead, in definite proportions, separates on cooling "regulus of venus," an alloy of antimony and copper $SbCu_2$, which was well known to the alchemists, and lead containing a small quantity of the same alloy. Dr. Ball, who has recently examined these changes, considers that the regulus of venus is dissolved in the lead, and being more soluble in the hot lead than when cold, the regulus separates out on cooling the alloy, leaving a cold saturated solution of the regulus behind, which then solidifies as regulus. Many alloys resemble metals in being capable of occluding gases, and Devray has shown that an alloy of rhodium and lead if treated with nitric acid gives after the bulk of the lead has been dissolved, a crystalline alloy of rhodium and lead, and a black residue which, when heated *in vacuo*, explodes and forms a brilliantly crystalline compound, which is soluble in *aqua regia*, whereas, before the explosion, it is insoluble in that solvent. Guthrie showed that the most fusible alloys of metals were not those which contained the constituent metals in molecular proportions.

RING v. MULE SPINNING IN INDIA.

A paper was read on the above subject by Mr. James Cocker, late of Bombay, at the Manchester Technical School, on the 12th inst. In his paper, the author pointed out that in the present days of competition it was absolutely essential that a mill manager should carefully attend to small details, and be able, by organisation, to bring out the fullest possible efforts of his work people. In commencing to compare the ring frame and the mule as competitive machines in the Indian market, he said that he was inclined to give the mule the first place for several reasons. The quality of the cotton they had to use, the current rate of exchange, the high price per spindle of rings with the accessories, and the cheap adult labour in India, all contributed to make the mule a cheaper instrument of production than the ring frame. He instituted a comparison between two machines, both spinning the same class of yarn, one fitted with 16,200 ring spindles, and the other with 19,610 mule spindles. In each case the rate of wages paid were the current rates in Bombay, and the comparison came out as follows, having regard to the fact that a ring frame of 270 spindles required a piecer for each side. For the whole of the labour required for the 16,200 ring spindles the cost per month was 1890 rupees, while for the 19,610 mule spindles the cost was 1216 rupees. Taking the production of the ring spindles at 6·9oz. per spindle for twelve hours, the production for twenty-eight days (which is the month on which wages are paid) is 195,608lb. The mule spindle produces 5·7oz. for the same working hours each day, equal to 196,608lb. per month. The cost per lb. was 1·85 pice in the case of the ring, and 1·19 pice in the case of the mule, an advantage to the latter of ·66 pice per lb. Comparing next the cost per spindle delivered in Bombay, the ring frames cost 8¼ rupees per spindle, and the mules 4·75 rupees per spindle, or a total cost of 133,650 and 93,147 rupees respectively. Making the usual allowance of one rupee per spindle for the extra floor space occupied by the mules, the latter cost 109,347, or 24,302 rupees less than the ring. Again it was necessary in spinning on the ring frame that a finer roving should be used. In spinning 20's for the China market, for instance, a 2·86 hank roving sufficed on the mule, while on the ring frame a 3·25 was wanted. The extra cost of this on the yarn produced was 150 rupees per month. Again the waste was greater on the ring than the mule, being respectively 3·93 and 1·48 per cent. The reason of this could, the author said, be demonstrated by a simple experiment—where 20's yarn with 15·86 turns per inch, and testing 46lb. was being spun a 6/0 traveller would be required. If the frame were stopped, the yarn marked close to the rollers, the frame re-started, and the number of revolutions of the rollers noted, it would be easy to ascertain the length which should be found on the spool. If the yarn were drawn off and measured from the rollers to a given mark, it would be found that there was ·75in. more yarn than the rollers were calculated to deliver. The same experiment with the mule would show that 1·73in. less than the calculated length was on the cop. If the same drag was put on the yarn in the mule as in the ring frame, and Surat cotton was used, the same waste would be made. The average margin between the manufactured article and the raw cotton for the past eighteen months was 4d. per pound. Allowing ½ per cent. for the lessened waste in reeling ring spun yarn, the excess of waste of ring over mule yarn was brought down to 2 per cent., equal to 733 rupees per month on the given quantity produced, to which should be added 150 rupees for the extra hank roving, making a total of 883 rupees or 8·1 pice per pound. A comparison comes out thus: Ring yarn, with common labour, 1·85 pice; extra fine roving, ·12; interest on the higher cost per spindle, ·1; extra waste made, ·71; a total cost per pound of yarn of 2·78 pice, against 1·19 pice per pound of mule yarn. The difference in favour of the latter was thus 1·58 pice per pound. In a brief discussion which followed it was generally agreed that the comparison, although possibly fair for India, did not represent the actual facts in this country, a proposition to which Mr. Cocker assented.

Reviews.

Transactions of the American Society of Mechanical Engineers. Vol. VIII.

This volume, which contains a record of the transactions of the fourteenth meeting at New York in November, 1886, and of the fifteenth at Washington, of the American Society of Mechanical Engineers, maintains the character of the volumes which preceded it for the value and originality of its contents. New societies, and especially those in new countries, seem to get out of the official and rather dry routine of older institutions, and while not in any way allowing the quality of their transactions to deteriorate, are able to present them in a more agreeable form to their members. At the very beginning of this volume we meet with an item which is rather apt to startle orthodox readers. It is a list of the members who have died since the institution of the Society. Their names appear immediately after the names of the present members, and they are to a certain extent still considered as belonging to the Society. The idea is good. Too often when a man dies he is forgotten, whatever his services may have been. In some Continental regiments it used to be the custom to keep on the lists the names of soldiers who had highly distinguished themselves, and they were called at the daily roll-call. Our societies might at least

Digitized by Google

record in their yearly volumes the names of some of their deceased members, who in their day have taken a prominent part in their proceedings.

The papers in the volume under consideration are very varied in their character, and somewhat unequal in value; but, as a collection, they reach a high standard and are well worthy of study. The first paper is a report of a committee on Standard Pipe and Pipe Threads, and it embodies a part of a paper by the late Robert Briggs, C.E., on "American Practice in Warming Buildings by Steam," printed in Vol. LXXI., Part I. of the Proceedings of the Institution of Civil Engineers of Great Britain, and which contains comprehensive information regarding the subject of standard pipe and pipe threads, as applied in American practice. While the Society did not endorse the Briggs' standard, still the opinions of the members were all strongly in favour of it.

The next paper, by Professor Reuleaux, of Berlin, honorary member of the Society, on "Friction on Toothed Gearing," will be read with especial interest by all of a mathematical turn of mind. Professor Thurston's paper on "The Friction of Non-Condensing Engines" enters on a subject which is well worthy of attention, that is, the efficiency of steam engines considered as machines, and we shall present to our readers the results of such investigations as may from time to time be made. In a paper on "The Strength of Shafting Subjected to both Twisting and Bending," Professor Lanza discusses Grashop's formula, and gives the result of some experiments he has made on the subject. While Mr. Benjamin Baker, of the Forth Bridge, contributes some useful notes on the working stress of iron and steel. The paper by Mr. William Cowles, on "Fire Boats," contains a large amount of information concerning the various types of floating fire engines which have been designed and built in America and England. Mr. George J. Alden summarises the investigations on the effects of the reciprocating parts of high speed engines, and gives tables and formulæ for calculating these. Mr. Kent's paper asks the question, Is Water Gas an Economical Fuel? and answers it in the negative. Mr. Oberlin Smith discusses the intrinsic value of special tools, and points out the necessity for large sums being written off yearly for their depreciation, as a change in the market might seriously reduce their value.

The next paper, by Mr. W. E. Partridge, on "Capital's Need for High Priced Labour," is intended to show that the labour troubles of employers, both in England and America, are largely due to a wrong theory in regard to wages, which stated in its simplest form is this: the less the price paid for labour, the less will the product cost; and he adds that this theory is so deeply rooted in the minds of both the labourer and the capitalist, that it has passed unquestioned from the early days of manufacturing to the present. The opinions expressed by Mr. Partridge, and by those who took part in the discussion, are worthy of very serious consideration both by capitalists and labourers; and we must confess we would like to hear of a few such subjects being discussed in our engineering institutions, as we are afraid by attending too closely to technical matters, they are apt to overlook those of more importance.

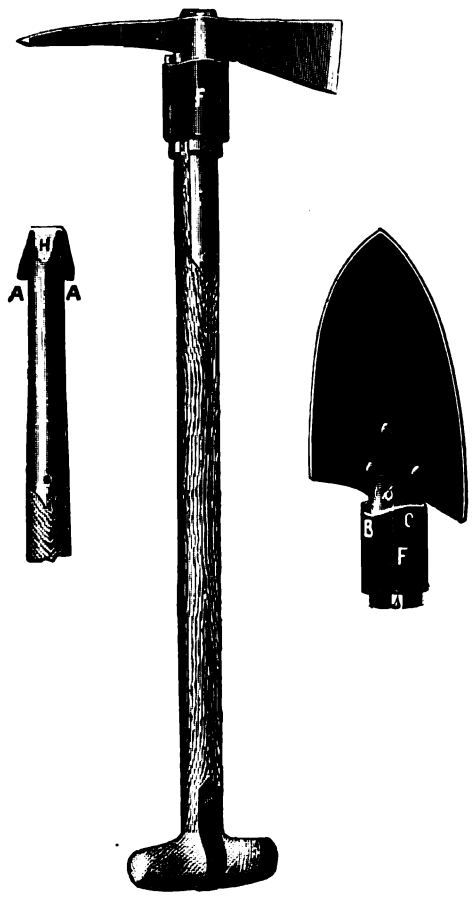
One of the most important papers in the volume is that by Professor Thurston on "The Systematic Testing of Turbine Water Wheels in the United States," and is based upon statistics and information from scattered sources, but principally gathered through the assistance of Mr. James B. Francis and of Mr. Clemens Herschel, and is interesting and valuable not only as a history, but also as a record of systematic experimental work. Mr. L. H. Rutherford brings a considerable amount of mathematics to answer the question—Should a piston packing ring be of the same thickness at every point? but we suspect that observation and practice will be more depended upon than the results of mathematics. The paper on "The Education of Intuition in Machine Designing," by Mr. John T. Hawkins, and the discussion upon it, opens up many questions connected with the teaching of engineering which deserve more attention than they usually receive. The writer concludes with Gibbon's remark that "we have two educations, one from teachers and the other we give ourselves," and he says what he wishes to contend for is, that the teachers should give us more of those things which we are obliged to buy, beg, borrow, steal, or dig out in some way for ourselves, and which, in machine construction, constitute the main requisites.

The next three papers are all of great value in the science of practical thermodynamics, all by Mr. Charles E. Emery: The first, on "The development of the compound engine, and the probable limit of steam pressure in marine engines and boilers;" the second, on "Cylinder condensation and the reduction of the same by the use of the compound engine;" and the third, on "The comparative value of steam and hot water for transmitting heat and power." Our space will not even in the meantime allow us to give a synopsis of these, but we may give some of their results on a future occasion. In the meantime we commend them to the attention of our readers.

Mr. Samuel Webber returns to a subject to which he has long given attention, viz., "The comparative value of different kinds of belting," and gives the results of a considerable number of tests. There are other valuable papers on the "Needs of the Navy," on "Coast Defence," on "Steam and Power," and other subjects, all of an interesting nature, which, with topical discussions, convey a considerable amount of useful information in a lively form.

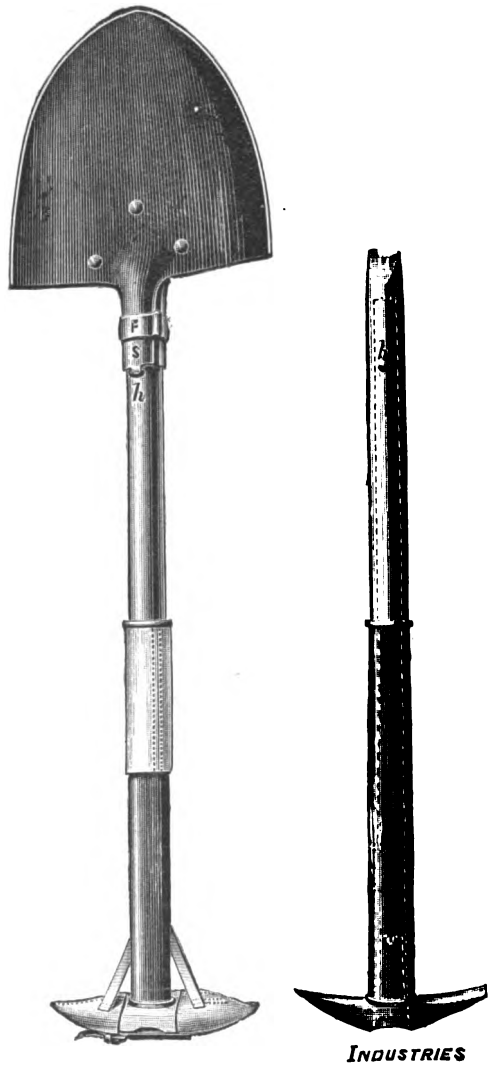
The President's Address comes at the end instead of the beginning of the volume, he being prevented by a long and serious illness from attending the meetings at the beginning of the session. Any address by Mr. Sellars is certain to be worth reading, and this one contains much that is deserving of attention, especially when he treats of the training and education of engineers; and he insists that the system of education which will teach the student to think and reason, without depending on fixed rules, will in the end be of the greatest practical benefit; and he notices some of the discussions which have taken place in this country. Altogether the volume before us sustains the high reputation of its predecessors, and bears evidence of the increasing prosperity of the American Society of Mechanical Engineers.

TECHNICAL EDUCATION AND FOREIGN COMPETITION. By Swire Smith, Member of the Royal Commission on Technical Instruction. London. 1887.



One of the most useful objects of the recently founded National Association for the Promotion of Technical Education is the preparation, in a popular form, of information to be obtained from reports of commissions, consular reports, and from various other sources, such as articles in reviews, so that correct information may be diffused throughout the country, and opportunities given for the discussion of the question from different points of view, and for the ventilation of opposing opinions. On the effect of technical education on the present state of our industries the most varied opinions are held and expressed, and it is only by free discussion that the truth is likely to be arrived at. Some writers and speakers seem to think that all the talk about the necessity for improved technical education is pure humbug; while others go to the opposite extreme, and look upon improved educational arrangements as the most pressing necessity of the present day. In this, as in all other questions, the truth is likely to be found between these two extremes. Sir Frederick Bramwell is not likely to be accused of any want of sympathy with technical education; but recently, in an address on "The Worth of Technical Education," he expressed opinions which ought to be carefully weighed by all who are studying the present economic condition of affairs. He said that our manufacturers would probably find that technical education had not restored to them the position which they had formerly held in regard to foreign competitors; that not only was this adjunct necessary to economical production, but that industry, thrift, liberty of labour, and the conscientious discharge of duty were still more important, and that without these we should never succeed in the race, whoever it might be against. An enormous amount of girder iron was now introduced into English buildings. That came to the London market almost entirely from Belguim. We ought not to have allowed the Belgians to introduce a single ounce of it. We had capital, raw material, coal of an unparalleled quality, and were not without inventors and inventive skill; the country was permeated by railways, a coasting service of the most complete description, and the most magnificent ocean fleet in the world. Yet we had allowed ourselves to be beaten in our own market; and however much the lack of technical education had had to do with that, it was not the sole cause—it was not 50 per cent. of the causes. He did not believe it was 10 per cent.; and those who expected such a condition of things to be put right again by technical education, would find that they had made a grievous error, and that other defects must also be remedied. Professor Huxley has also, in his recent speeches and papers, pointed out that unless we take care all our present methods of technical education are merely quicker ways of going to ruin, unless we at the same time take steps to secure the stability of the social structure.

The first paper issued by the National Association for the Promotion of Technical Education is that named at the head of this notice, and it is a very moderate statement of experience and observation, and attracted a considerable amount of attention at the time it first appeared in the *Westminster Review*. From his position as a member of the Commission on Technical Education, Mr. Swire Smith had every opportunity of ascertaining facts, and the inferences he draws from these seem to be fully justified. He gives a short sketch of the industrial growth of Britain, and contrasts present with past conditions. He points out that the old system produced infinitely more skilful men than the modern one—some of their products being the despair of modern imitation; but aided by science and invention in utilising the forces of nature, the manufacturers of England were able to flood the markets with the cheap products of organised mechanical industry, while our rivals, clinging to past conditions, holding on to past methods, worked their fingers to the bone in vain efforts to earn a living. But the commercial prosperity of England, promoting as it did the industrial advancement of the world, soon began to be felt in other countries. Foreigners came over and bought English machinery; they employed English architects for the erection of their factories; English foremen for directing them. They adopted our methods of manufacture and organisation, and they copied from us every good thing we could teach them. They learned our strong points, and did not fail to take careful note of our weak ones; and as a result, finding it impossible to compete with us in machinery, they turned their attention to the cultivation of their men—already more highly educated than our own. Their supply of labour was practically unlimited, millions of men being eager for employment at low wages.



As far back as the Exhibition of 1851 the fact was clearly demonstrated that we were lamentably behind our foreign rivals in the application of art to manufactured productions, and this was what set the Prince Consort and others to organise the Science and Art Department at South Kensington, and local bodies to institute schools of design and mechanics' institutes. But there were two great difficulties which impeded the success of the movement; apprentices were invited to study design who had never learned a stroke of drawing, and in many instances could neither read nor write; on the other hand manufacturers, blinded by their prosperity without art, viewed with perfect indifference and apathy the movement for the artistic training of their men, and only in exceptional cases supported it, and the result is that we are much behind our Continental neighbours both in scientific and art training. Mr. Swire Smith remarks, that what is chiefly remarkable in all this existence of national ignorance of art or science is the fact, that for many years the great bulk of the industrial classes, both employers and employed, could not be made to believe that they were one penny the worse of it. Our insular pride and prejudice encouraged the fallacy that we commanded the machinery, the capital, the skill, and the knowledge, and therefore that success was assured, and could not but be enduring. Soon, however, effective foreign competition gradually and almost imperceptibly began. The inventions of England were no longer England's monopoly; they were distributed over the world, and every new foreign factory that was built combined the latest English improvements with the equipments of our most modern machines. Moreover our rivals were often able to shut out our products by high protective duties, although to a certain extent this policy gave a stimulus to the export of machinery, factory and workshop appliances, and raw and semi-raw materials from England. The results, however, were often disastrous to the manufacturers. But for us the serious part of the question was not simply that we have lost our trade in staple cheap goods with foreign manufacturing countries, but our enterprising Continental rivals beat us in their own countries in common goods by their tariffs; but they also beat us abroad in some classes of superior goods by their skill, taste, and commercial aptitude—the qualities which they have so assiduously taught in their schools, and which have been so grossly neglected in ours. These facts were strongly impressed upon the Commissioners on Technical Education, of which Mr. Swire Smith was one. They visited the schools, conversed with the professors and students, and on returning to England they visited competing establishments, and tested the foreign evidence face to face with all the facts in our own country. They obtained undoubted evidence proving that, in so far as economy of production is concerned, English manufacturers, despite the higher wages and shorter hours of English compared with those of foreign workmen, have nothing to fear. In respect to machinery, organisation, spirit, and energy, Mr. Smith does not think the Commissioners were blinded by undue partiality in giving the foremost place to English employers and operatives, although in respect of these points the rapid progress of our German rivals during recent years shows unmistakeably that there must be neither rest nor sleep if we are to maintain our ground. The best machinery everywhere is English, in some of the weaving factories even the yarn is English. The superiority of the foreign establishments is not in machinery, but in the men; not in natural faculties, but in training. Mr. Smith enters into various questions connected with tariffs, and discusses the educational arrangements which are necessary in order to enable us to hold our own. These, however, our space will not allow us to describe at present; but we trust that Mr. Smith's pamphlet will be widely and carefully read, and that the National Association for the Promotion of Technical and Commercial Education will continue to place before the public such information as will enable them to form exact opinions on the subjects which are now attracting so much attention.

COMBINED PICK AND SPADE.

FIGS. 1, 2, AND 3.

FIGS. 4 AND 5.

COMBINED PICK AND SPADE.

THE illustrations which we give herewith show a new combined pick and spade, invented by Major W. C. Underwood, of the 4th Hussars. Figs. 1, 2, and 3 represent the cavalry type, and Figs. 4 and 5 the infantry pattern. In the cavalry type, a wooden shaft is employed, having at one extremity a steel head H, with side projections A A, the head being inserted into the socket of the pickaxe or shovel. The fastening is by means of a ferrule F, provided with two grooves to allow the projections A to pass. When right home the ferrule is turned, and its sloping edges B C engage with the projections on the head of the shaft, thus making it fast in the sleeve S. The weight of the tool, with leather frogs and cases, is 4lb., and the shaft may be used for tethering the horse. The shaft of the infantry tool (Figs. 4 and 5) is a light hollow steel tube, which forms a scabbard for the bayonet, and at one end of which is a solid welded steel pick. This serves as a handle when the spade is fixed to the other end H, in which case protection is given to the hands by the leather covering by which the shaft is suspended from the soldier's belt. The spade is attached by means of an oval ferrule F, which, sliding over the tapered sleeve S, forces tags into the holes *h*. The spade can, by straps attached to its leather cover, be hung from the chest buttons of the tunic, and, owing to its having an oblique face and being made of steel, has been found capable of resisting rifle bullets at ranges over 200 yards. The total weight of this tool, with leathers, is 2lb. 7oz. In addition to the military uses to which these instruments can be put, the inventor, who recently exhibited them at the Royal United Service Institution, points out that the cavalry pattern would be valuable for emigrants or explorers, and the infantry pattern for gamekeepers, a steel rod being substituted for the bayonet in the latter case.

THE largest gas engine ever manufactured in the Wear district has been on view for some time at Messrs. Rideal gh, Fairman, & Co's., of Sunderland. The engine indicates 27 h.p., and is intended to work four lifts in the Sunderland Co-operative Societys' warehouse. The space occupied is only 6ft. sq. by 10ft. high.

ON THE COST OF CENTRAL STATION LIGHTING.

BY R. E. CROMPTON.

AN article under the above heading appeared in *Industries*, page 598, Vol. III., and it professed to deal with the comparative costs of distributing electricity by the three kinds of transformers now available, viz.: (1) accumulators used as transformers; (2) what Sir William Thomson calls "step down" dynamos used as transformers; (3) the well known alternating transformer system as used on the Grosvenor Gallery installation, and also by Westinghouse and others. In that article, a great deal was said as to the great advantages, in point of cheapness, of the system I have placed third in order; and I will now proceed to show how the conclusions arrived at in that article may be considerably modified in favour of the accumulator transformer system, if the latter be treated in a somewhat different manner to that proposed by the writer of the article. I think he put this system in a false position by going too far in the direction of reducing current and increasing the e.m.f. No one will doubt that in a large number, in fact in the majority of cases, the generating station can be placed at a distance not exceeding one mile from the nearest part of the district requiring electricity for lighting or motive power purposes, and I propose to show that in these cases when battery transformers, or what I shall briefly call the B.T. system, is used, the cost of the plant will only slightly, if at all, exceed that for an equivalent supply from alternating transformers, which for convenience I shall call the A.T. system. I prefer not to compare what might be done, but what has been actually and successfully done in the way of transforming by batteries with what has been done by alternating transformers.

At Vienna, the system proposed by M. Monnier, and successfully carried out by myself, consists of charging from a central station, groups of batteries of accumulators, charged continuously in series. From each group four circuits are led off so as to cut down the e.m.f. from 400 volts to 100 volts to suit the lamps used. This system has now been in use continuously for six months, and there has been no hitch or trouble whatever in working the plant. It is almost needless here to remark that the troubles connected with the boilers about which so much has been written, have had nothing whatever to do with the electrical plant. No difficulty has been experienced in charging continuously at the high pressure necessary, and although no special precautions were taken with the inside wiring of the opera, and other places supplied, no danger or difficulty has arisen from the use of this high pressure. We may therefore consider it proved that a system of supply which uses a charging current at a potential sufficient to fully charge four batteries arrangod in series each at 100 volts, and which supplies at times of average maximum demand for electricity, two-thirds of the current direct from the dynamos without any loss whatever, and one-third only from the accumulators, can be worked successfully and economically, and with a far greater margin of security against temporary stoppages of the light than could possibly be the case with either alternating or direct current transformers without storage.

It remains now to compare the cost of the B.T. system when applied to an installation of the dimensions proposed in the article, with the figures given as the cost of the installation by alternating current transformers. Taking the items in the order previously given, I shall consider first the cost of motive and dynamo power. As I have said, the dynamos supply two-thirds of the maximum net output of 600 kilo.-watts, and as in this case there will be no loss of current, but only of e.m.f., in the regulating appliances, which may be safely taken at 12 per cent., we require 448 kilo.-watts at the terminals of the batteries, or, adding the 10 per cent. loss in the mains, 500 kilo.-watts in the generating station. If I add to this the 20 per cent. of extra motive and dynamo power the writer of the previous article proposes to allow as reserve, we must provide for 600 kilo.-watts, equal to 1000 i.h.p. Such a plant may conveniently consist of six sets of combined engines and dynamos, each of 100 kilo.-watts, or 166 i.h.p.

£12 per i.h.p., the sum allowed in the former article, appears to me an excessive estimate for engines and boilers only, and as it tells equally on both sides of the comparison, I propose to reduce it in both cases to £8. 12s. per i.h.p., for which sum I believe more than one contractor of repute could be found ready to supply and fix the boilers, steam and exhaust pipes, feed apparatus, triple expansion engines, ready to be coupled on to the dynamos. I adopt the figures given as the cost of the dynamos, and from the two I work out the cost of the motive power to £8,700, and the dynamo power £4,800. For the A.T. system I adopt the figures formerly given, viz., 1450 i.h.p., which at £8. 12s. comes to £12,500, and for the dynamos and exciters £5,540. For purposes of comparison, a sum ought to be added representing the cost of site and buildings in both cases, and as stated in the article, the cost of this would be nearly in proportion to the space occupied by the machinery. I propose to add on this account £8,000 to the B.T. system and £11,000 to the A.T. system. Next as to cost of charging mains. As I read the article, these mains in the case of the B.T. system will extend only from the generating station to the accumulator stations in the district. If we take the length of this main at one mile exterior to the district, and 240 yards inside it, or 2000 yards in all, the total length of circuit being 4000 yards, the current 1200 ampères, and a loss allowed of 10 per cent. or 40 volts, its resistance must be 0·04 ohm. A double conductor, having a collective area of about 2·55 sq. in., weighing about 45 tons, and costing at £80 a ton, £3,650, will be sufficient. This can be laid, supported on earthenware or porcelain insulators, in a brickwork-in-cement culvert, for £1,500, or, say, £5,150 in all. In the case of the A.T. system, the mains, for purposes of comparison, must be laid under ground, and as in this case the charging mains are practically co-extensive with the charging as well as the distributing mains of the B.T. system, it will be convenient to consider the cost of the street work as common to both. The cost of the cheapest and most trustworthy method of laying distributing mains under flag footways, and under ordinary street crossings, varies in London from 14s. a yard of double main, if the section is as small as would be laid for carrying 40 ampères, to 16s. per yard, if conductors having ¼ sq. in. of section of copper are used.

Before proceeding further, it is necessary to consider what length of house frontage will be probably required for a supply of 10,000 60-watt lamps burning simultaneously. I believe recent experience in London and elsewhere has shown that the ampère at 100 volts, *i.e.*, 100 watts per yard of useful frontage of houses supplied, is a good figure to use. For the 6000 ampère or 600 kilo.-watts we supply 6000 yards of useful frontage, and this on the supposition that every house takes the light. But it is not unreasonable to say that for years to come 50 per cent. in excess of this frontage must be supplied with mains, or 9000 yards actually facing the houses, to which we must add at least 35 per cent. for crossings and other portions of the road traversed by the mains, which do not face what I call useful frontage. This makes

ON THE COST OF CENTRAL STATION LIGHTING.

COST OF GENERATING AND DISTRIBUTING PLANT FOR 10,000 60-WATT GLOW LAMPS, BURNING SIMULTANEOUSLY.

With Secondary Batteries.

	£	s.	d.
Motive power, six 166 i.h.p. sets = 996 i.h.p., at £8. 12s.	8,700	0	0
Dynamos	4,800	0	0
Building to suit above	8,000	0	0
Charging main, 45 tons at £80	3,650	0	0
Laying ditto in culvert	1,500	0	0
Distributing mains, 12,000 yards at 16s. per yard	9,600	0	0
Service boxes, 450 at £2	900	0	0
Batteries, four sets of 50 cells each	8,640	0	0
Regulating gear	1,000	0	0
	£48,790	0	0

With Alternate Current Transformers.

	£	s.	d.
1450 i.h.p., at £8. 12s. per i.h.p.	12,500	0	0
Dynamos and exciters	5,540	0	0
Building to suit above	11,000	0	0
Charging main	2,400	0	0
Distributing main, 12,000 yards at 14s. per yard	8,400	0	0
Service boxes, 450 at £2	900	0	0
Regulating gear	500	0	0
Transformers, assuming one large one for two houses, 300 at £25 (including fixing) =	7,500	0	0
	£48,740	0	0

12,000 yards in all. From the figures I have before given, these 12,000 yards of distributing mains for the B.T. system, at ¼in. section of conductor, would cost £9,600; and those for the A.T., at the smallest useful section, would cost £8,400. To the latter figure must be added an item of £2,400 as the cost of one mile of main outside the area of supply. Before leaving the subject of the distributing mains, it will be convenient here to consider the question of the cost of the house connections. When underground conductors are used, it is necessary to provide one surface box with connections for every two houses. Now, as the whole of these must be put down in the first instance at the time the mains are laid, we must estimate for their supply for both systems. In London the house fronts vary from 24ft. to 60ft., and taking the rather high average of 30ft., or 10 yards, we would require a surface box for every 20 yards, or 450 boxes for the 9000 yards of useful frontage. Pricing these at £2 for each surface box fixed, we must add £900 to both estimates.

The battery transformers have to supply 200 kilo.-watts per hour during the hours of maximum supply. A great deal hangs on this most important question of the duration of the hours of maximum supply, but in London it is found not to extend beyond three hours per day in winter. If we supply four batteries of accumulators which will have a total capacity of 1000 kilo.-watts, we shall provide for five hours of extreme demand, which is a condition of things extremely unlikely to occur, even in times of fog. We require thus four batteries, each having a capacity of 250 kilo.-watts and capable of being discharged at fair efficiency, at a rate of not less than 650 kilo.-watts. Such accumulators can be obtained either in England or on the Continent from at least three different makers, and can be fixed and set to work for the sum of £8,640. In one of these cases, the makers guarantee that to meet a breakdown of the charging plant or of the charging mains, a demand at the rate of 250 kilo.-watts can be supplied by each battery without injuring it in any way, but of course for a comparatively limited period. This would provide against any panic or annoyance to the users of the light caused by a temporary stoppage of the charging current, even if it occurred at the period of maximum demand. In all such cases as this which I am now estimating, when ample allowance has been made for spare machinery, and when the charging mains can be laid and insulated in two parallel sections, such stoppages are unlikely to extend beyond a few minutes, so that in this point the B.T. system offers enormous advantages over its rivals.

The cost of the alternating transformers appears to have been largely under estimated in the former articles. The writer there stated that a maximum supply of 10,000 lamps would be obtained from such a small number as 150 transformers. Most people will admit that such distribution is extremely unlikely to occur in London, whatever might be the case in New York or some of the Continental towns. When I was above considering the distributing mains I showed that 9000 yards of mains fronting the houses would be required in order to obtain 10,000 lamps lighted simultaneously, and I suppose that these mains would front 900 houses, of which only 600 would take the light. It follows that, if every consumer has his own transformer fixed, 600 must be provided, and at the lowest estimate this could not be done, including the fixing of them, at a less charge than £20 per house, or £12,000 for the whole. Even if we suppose that one transformer could be provided for every two houses, we cannot estimate the total cost at less than £7,500; and in order to avoid possible criticism on this ground, I propose to enter this lower figure in my comparative statement; but it will be very interesting to hear the opinion of the advocates of the A.T. system on this point, as it very vitally affects its first cost. The statement I have thus arrived at shows that the cost of 10,000 60-watt lamps supplied simultaneously will be approximately the same, viz., £49,000, for both systems, a result which differs very widely from the figures given in the previous article. I leave the figures to speak for themselves, and shall have more to say on the matter after I have heard a few of the criticisms which I may reasonably expect from those who believe in the A.T. system.

STATISTICS OF FIRE TELEGRAPHY.

AT the Society of Telegraph Engineers and Electricians a paper on the above subject was read by R. von Fischer Treuenfeld, F.R.G.S., Member. The title of the paper was "The Present State of Fire Telegraphy;" but as this title might induce our readers to think that the author dealt with technical and scientific improvements in the apparatus used, we have taken the liberty of altering the title to that given above. The paper was by no means technical or scientific, it was entirely statistical, but nevertheless of great practical value, and likely to direct public attention to a much needed improvement. Why this paper should have been read before the Society of Telegraph Engineers and Electricians is, however, difficult to understand; it would have been far more suitable for the Statistical Society. The author referred to his having, eleven years ago, brought the subject of fire telegraphy before the Society and the British public, when he showed by statistics that a considerable reduction in the percentage of "serious fires" could be attained by the adoption of a system of fire telegraphs, and especially of street call points. As early as October, 1861, Messrs. Siemens Brothers had proposed to introduce a system of the kind into Manchester; but it was not carried out, owing chiefly to the fear of the Town Council that false alarms would be frequent. The same fear delayed the introduction of street call points in London until 1880; but subsequent experience has shown that though much inconvenience is caused by false alarms, this is greatly overbalanced by the advantages of the system in giving early notice of fires to the fire brigade stations, and thereby reducing the proportion of fires of serious dimensions. The author has collected statistics referring to British, American, and Continental towns, and found that where the system of fire telegraphy is fully developed the ratio of serious fires is only about 4 per cent. of the total number, while in towns totally unprovided with such a system the percentage rises as high as 29. By a "serious fire" is to be understood one for the extinction of which more than two engines or reels of hose are required; but this standard is not always adhered to, so that it is impossible to make the statistics strictly comparable throughout. It was pointed out in the paper that the periodical decrease in the percentages of serious fires must be attributed in part to the increased efficiency of the fire brigades, as well as to the extension of systems of fire telegraphy. The author considered that though the number of alarm points has generally increased in British towns, we are still in this respect very much behind the towns of America and the Continent. The statistics do not give any direct evidence that the extended use of fire telegraphy lessens the loss of life through fires, for through the action of other causes, such as the crowding together of factories and warehouses, the proportion of lives lost to the total number of fires shows a general tendency to increase.

Mr. Sharpe considered that factories and warehouses should have automatic fire alarms, but that the slowness of action and want of reliability of those hitherto used had prevented their general introduction, and also the fact that they required the use of closed battery circuits, with a consequent waste. He referred to a system described in the *Electrical Review* for 1st March which he asserted met these difficulties.—Mr. E. B. Bright was in favour of using automatic alarms, and created considerable amusement by stating that when he had tried to persuade the insurance companies to take them up he had been informed by an insurance manager that the companies did not want to abolish big fires, as whenever these occurred they brought so much new business.—Mr. Higgins confirmed Mr. Bright's experience of the attitude of the insurance companies, and complained of the apathy of the public on the subject. He stated that he had introduced a very efficient and inexpensive system, but had only succeeded in getting six subscribers in three years.—Mr. H. E. Hall, who spoke on behalf of the insurance companies, said that though certainly if fire extinguishing arrangements could be so perfected as to make the public consider insurance a waste of money, the companies themselves would be extinguished; still they did not want big fires. What they would like if they could choose, would be a fire from time to time in outlying districts like Hampstead to stimulate business, and an absence of fires in the City, not involving absence of premiums. He considered unreliable automatic alarms a source of danger, as tending to produce a false sense of security, and also that having sprinklers and other amateur fire extinguishing apparatus in houses often prevented an early alarm being given, as the inhabitants thought they could manage the fire themselves. He thought one reason for the diminution of the proportion of serious fires was that the districts consisting of private houses and small shops where there would not in general be serious fires, was always extending, while the City, where the fires generally were serious, necessarily remained stationary in area.—Captain Shaw had not yet found any reliable system of automatic fire alarms, though large numbers had been submitted to him. He considered the establishment of street call points a great benefit, in spite of the trouble given to the brigade by false alarms. During the past year they had received 826 good calls, and 375 false ones, arising from various causes, carts running against the posts and other accidents, calls due to malice or love of mischief, or from some one seeing smoke coming from a chimney, and thinking that it was due to a fire. He thought it would be very desirable if some means could be devised by which the giving of an alarm from a public call point should involve the production of a noise sufficient to rouse the neighbourhood within a radius of a hundred yards, which he thought would be effective in preventing malicious tampering with the instruments. He considered bells objectionable, as being so liable to be rung accidentally, and would prefer for public and private alarms some telephonic or other system by which details of the fire could be given.

As examples of the statistics upon which the above conclusions are based, we give below a table of London fire statistics, and also one giving the fire statistics of Amsterdam, a town which possesses an exceptionally complete system of fire telegraphs.

LONDON FIRE STATISTICS.

Year.	Number of points at which fire alarms can be raised.	Proportion of alarm points to inhabitants.	Percentage of serious fires.	Lives lost per 100 fires.

A NEW COMMERCIAL APPLICATION OF OXYGEN.*

THE want of some simple method of obtaining a powerful source of heat under perfect control is an experience which all who have charge of machinery and chemical plant must have felt more or less frequently. Up to the present time the only practical methods have been either the use of a basket of live coke or a blowpipe connected to the nearest gas supply. Neither of these methods is satisfactory in many cases, and, to overcome the difficulty, I have devised some special forms of blowpipes

* Paper read before the Liverpool Section of the Society of Chemical Industry, by Mr. Thomas Fletcher, F.C.S., on the 7th inst.

Digitized by Google

which can be used with the ordinary coal gas supply and compressed oxygen made by Brin's process. These blowpipes are essentially different from the usual form, and also from the well known mixing jet, the latter requiring both gas and oxygen to be equally compressed, which at once excludes it as an emergency arrangement for repairs. It is pretty well known that air gas produced from gasoline vapour, when used with an air blast in a blowpipe, is peculiarly liable to be extinguished; the speed of combustion is sufficiently slow to enable the flame to be blown out, or away from the unburnt vapour, with the greatest ease, probably owing to the fact that the gasoline is not diffused through the air as a true gas, but as a vapour, which requires further heating and considerable expansion before it will burn. On this point a rather pretty experiment will be given, showing you the particles of vapour in the so-called air gas, burning separately, the flames of the separate suspended beads of gasoline vapour being distinctly visible as independent centres of combustion. When we apply an oxygen blast to gasoline vapour this brittleness or want of persistence disappears; but owing to the air mixed with the vapour, the temperature obtainable is far lower than that from permanent combustible gases, and up to the present time high temperatures have not been obtained with blowpipes using the light petroleums, owing to the necessary mixture of air to obtain the vapour. It must not be forgotten that when gasoline or benzoline vapour is used, it has one special point in its favour for some classes of work in the fact that the products of combustion are quite free from sulphur, which in many ways is a great source of trouble in laboratory work. The use of a petroleum or spirit spray, if it were practicable, would overcome the difficulty of the admixture of air; but the spray formed by an oxygen blast is of a most unpleasantly uncertain and explosive nature, so much so that after my own experience I can only give a strong caution as to the excessive care required to prevent disastrous accidents. A spray burner may start and work satisfactorily, and then suddenly, without any apparent cause, the whole apparatus may be shattered into fragments. When we burn a permanent gas, such as hydrogen or coal gas, in a blowpipe with an air blast, the flame will bear a heavy air pressure on the jet, giving a correspondingly high temperature flame. If we take the same permanent gas, and use it with a jet of oxygen instead of air, the persistence of the flame is again greatly increased, the speed of traverse of flame backwards is so great that the amount of combustion which may be going on in a given space is almost unlimited, and enormously high temperatures can therefore be obtained with the greatest ease, the absence of nitrogen in the flame, of course, greatly assisting the result by reducing the loss of heat, and we gain also by the smaller area of flame containing a given number of available units of heat.

In the construction of powerful blowpipes for compressed oxygen, and coal gas at ordinary pressures, the form of the jet is a very important matter. The centre jet, instead of being formed with a single hole (except in the very smallest sizes), should be flat on the end, and drilled with a circle of very fine holes, each large enough to pass from 3 cub. ft. to 4 cub. ft. of oxygen per hour at a heavy pressure. The gas outlet which surrounds this jet should be an annular space about $\frac{1}{16}$in. wide surrounding the jet, and should project $\frac{3}{8}$in. beyond the tip of the jet, this projection being the same for all sizes and powers. Such an arrangement is useless for a gas and air blowpipe, as it extinguishes itself instantly, and considerable experimenting has been necessary to arrive at the details now given. With me I have three sizes of these blowpipes, requiring respectively about 7, 20, and 40 cub. ft. of oxygen per hour; and with a small bottle of compressed oxygen, which can readily be carried under the arm, I will now give some idea of their power. The quantity of oxygen required for each has not been measured by myself, but has been estimated from a bottle supplied by the Brin Oxygen Company, which I was informed contained 20 cub. ft., and which has supplied the largest blowpipe at full power for half an hour continuously. The smallest of these blowpipes will fuse the end of a $\frac{3}{16}$in. wrought iron rod; the next size will do the same with a $\frac{1}{2}$in. wrought iron rod, or will braze copper pipes $\frac{1}{2}$in. thick about as quickly as a tinman can soft solder light sheet tinned iron. The largest size will fuse a hole through a 4in. wrought iron steam pipe, and will braze, and probably also weld, heavy flanges and couplings on work of the same size. Larger blowpipes can be easily made on the same lines, and it is now both possible and easy to braze and make repairs in parts of complicated machines without removal in any place into which a man's hand can be got. The heat is so local and so quickly obtained that, with the assistance of wet cloths, polished work or wood lagging can be preserved without injury within two or three inches from a place where a heavy brazing repair is being done. Breakdowns in copper pipes or vessels can be made good and work re-started in a few minutes which under ordinary conditions would necessitate several days' stoppage. Using the same blowpipe and bottle of oxygen, I will show, with a block of lime, an emergency light which will often be found useful; amongst other things it will enable you to get by photography a permanent record of any accident or unusual state of things in places where no natural light can be obtained, and where magnesium would fail owing to the dense fumes evolved. This light is, of course, anything but silent; but as we are now considering only works emergencies, the noise is not of any great consequence. Turning now to the laboratory, as many members will know, I have identified myself for many years with apparatus for the production of high temperatures for experimental purposes, and the cheap production of oxygen has advanced our powers in this direction very considerably. When any new application of a power is discovered, my own instinctive feeling turns at once to its application in the chemical laboratory, that source from whence a very large proportion of our commercial knowledge and power has originally sprung. It is not only necessary that a new power shall be known in the laboratory; the most important point from a practical point of view is that it shall be easily and quickly applied to useful research by those whose time is limited, and the elements of time and personal trouble must be eliminated as much as possible.

My first attempts to utilise compressed oxygen for laboratory gas furnaces proved total failures, owing to the intensely local heat evolved, which entailed the cutting and destruction of every crucible used. The direct application of the heat to the contents is in many cases out of the question, and after some experimenting I found that the desired result could be obtained by mixing air with the oxygen blast, so as to increase the size of the flame, and spread the heat more evenly over the surface of the object to be heated. The form used for this purpose is similar to the well known injector blow pipe, the air jet being, for a small laboratory furnace, $\frac{1}{4}$in. bore and open at both ends, and behind this is a small oxygen jet pointing directly along it. When the oxygen blast is turned on it carries along with it about four or five times its bulk of air. Having got so far, I was again blocked by the fact that no known casing suitable for gas furnaces would stand the heat obtained, even for a few minutes. The only kind of casings which can be satisfactorily used for laboratory gas furnaces are composed of a mixture of very refractory clay and ground cork or sawdust; when these are fired in a kiln, the woody matter is burnt out, and a porous material is left, which offers a most extraordinary resistance to the passage of high temperatures through it. It is, as is very well known, an easy matter to fuse cast iron in a crucible in a casing of this material only 1in. thick, before the outside of the casing has time even to become slightly warm to the hand. The objection to this mixture is that the salts contained in the wood or cork are not burnt out, and they remain acting as a flux on the refractory clay, reducing its resistance to fusion to a very serious extent. This difficulty has, however, with the assistance of the Morgan Crucible Company, been at last overcome, and as the increase of power in our guns leads to improvement in armour plates, so has the increase in power of our laboratory furnace burners led to an improvement in the resisting power of the crucible casings which have to withstand their destructive power. By the discovery of a very refractory clay, which has practically the same contraction as the porous mixture, it is now possible to line the furnace casings with a thin layer, which offers an extraordinary resistance both to fusion and also to the action of fluxes. That these casings are only in their preliminary stage, and not at their most perfect point, goes practically without saying, and only a few have been made up to the present time. One difficulty not yet perfectly overcome is the tendency of the refractory lining of the lid to tear loose, owing to the thinness and the slight hold available; this is, however, only a question of detail which will shortly be overcome.

With the injector furnace, which is undoubtedly of great value for chemical research, I have for some years been held in check by the fusibility of the casings, and this has of necessity put a very definite limit to the power of the burners which could be employed. As this limit is now, or very shortly will be, greatly extended, there is an opportunity for further experiments on the air and gas burners for ordinary use, irrespective of the new power we have now at command. Using the combined air and oxygen burner with one of the new casings, it may be shown that any power, from the lowest to the highest, can be obtained with the greatest ease, and without attention, as one of the small oxygen bottles will work this furnace at full power for about 2½ or 3 hours, and at lower powers for a correspondingly longer period. I have already expressed an unfavourable opinion as to the use of gasoline or benzoline vapour for use in open blowpipes, but this objection does not exist with furnaces where the mixture is blown on to a surface at a high temperature, which insures perfect combustion and persistence of the flame. The only working objection to the oxygen blast in gasoline or benzoline vapour furnaces at present is that a supply of air must be blown through the generator to produce the combustible vapour.

Whilst experimenting, it is the nature of chemists to consider the expense after the money is all gone; in fact, if this were not fortunately the case, very little original work would be done, and to follow this old established rule, now all my oxygen is gone we will consider the expense. In the first place, owing to the great concentration of the heat, the loss in use is exceedingly small; the nitrogen, which in an ordinary blowpipe flame is a source of great waste, is partly or entirely absent, and as a consequence the coal gas consumed is in practice only about one-sixth of that required to do the same work if an air blast is used. The oxygen, if made on a large scale, can be produced by Brin's process at a cost varying from 2s. to 7s. per 1000 cub. ft., depending on the quantity made. In the steel bottles the compressed gas is now sold at from 2d. to 3d. per cub. ft., which is, of course, a high price for work on anything like a commercial scale; but if we keep a few small bottles of compressed oxygen ready for emergencies, their value may, in some cases, be more than a thousand times their cost, and the expense becomes, therefore, a minor consideration.

It may be well to mention, whilst dealing with this subject, that compressed liquid nitrous oxide has been used for small blowpipes for platinum working; but it is not only very much more costly than compressed oxygen, but it is also not so satisfactory. With the oxygen, repairs of platinum vessels in the laboratory become a very easy matter, and the ordinary forms of blowpipes can be used for this purpose, provided a small jet is used and the outer cap is kept about $\frac{3}{8}$in. in advance of the jet. This is necessary to obtain a rough flame for general heating, a fine pointed flame being liable to cause perforation of the vessel instead of producing a broad welding surface. If the compressed oxygen is to be at all freely or generally used, the price charged must be greatly reduced, and, judging from the first cost of the gas, I certainly can see no reason why so high a price should be charged, as the bottles last practically for ever, and the cost of compressing must be very small.

In the discussion which followed this paper the Secretary stated that having regard to the ease with which Mr. Fletcher could fuse a hole through an iron plate by means of the large blowpipe shown, a burglar proof safe no longer existed, as a chilled iron or steel plate could be perforated almost as quickly as a carpenter could make a similar aperture through a wooden door. This was, he said, a very serious matter indeed for bankers and others having charge of valuable property, and would require the immediate attention of safe makers, as it was well known that the professional burglar was ready to utilise the latest applications of science to further the ends he had in view. That Mr. Fletcher's inventions have been made use of in this way could be seen any day in the detectives' museum at Scotland Yard.

Since the above paper was read, we have had an opportunity of witnessing at Mr. Fletcher's works several experiments as carried out with the large size blowpipe referred to in his paper, and we may briefly state that the apprehensions expressed during the discussion which followed the reading of the paper are not in any sense imaginary or exaggerated. Ordinary coal gas and oxygen were used for the blowpipe, the oxygen being manufactured by Brin's process, and supplied in steel bottles of cylindrical form, measuring about 2ft. in length by 5in. in diameter, the ends being hemispherical. These bottles when fully charged are said to contain 20 cub. ft. of oxygen at atmospheric pressure. One experiment was intended to show the effect of the blowpipe flame upon a ¼in. iron plate, and the result was almost similar to that of a chemical plumber's small blowpipe upon a sheet of lead of equal thickness, for in 30sec. a hole was fused through the plate, and by continuing the action of the blowpipe a straight slot was fused in the plate at the rate of 1¾in. per minute. From these results it may be easily imagined that an operator having burglarious intentions would, if provided with Mr. Fletcher's blowpipe and the necessary supply of gas and tubing—which could easily be arranged in a portable form—subject our best safe makers' work to a much more severe test than they have hitherto anticipated. There is fortunately, however, an industrial side in connection with this blowpipe, and we would recommend boiler makers and copper smiths to make themselves acquainted with its powers, as we have no doubt that by its use some repair work could be carried out in a fraction of the time that is now required.

THE RECOVERY OF SULPHUR FROM ALKALI WASTE.

On Monday, the 5th inst., at a meeting of the Society of Chemical Industry, held at Burlington House, Mr. A. M. Chance read a paper upon "The Recovery of Sulphur from Alkali Waste, by means of Lime Kiln Gases." In 1837, Mr. Gossage began researches on this subject, followed later on by Schaffner in Germany, Mond in England, and Mactear in Scotland, without results of more than limited practical application, although the more recent process of Schaffner and Helbig gave promise of more substantial effects. In July, 1882, Mr. C. F. Claus took out a patent mainly for the purification of coal gas, which he (Mr. Chance) thought might be applied to recover sulphur from the sulphuretted hydrogen liberated from vat waste by means of carbonic acid, so he made terms with the controllers of this, and several other of Claus' patents. In the process under which was produced the sulphur upon the table before them, a regulated mixture of sulphuretted hydrogen and air passed under the perforated bottom of a circular kiln, lined with fire brick, first through a bed of broken fire brick and then through a layer of oxide of iron. The steam and sulphur vapour produced passes along the outlet pipe into a small brick chamber, and thence into a large brick subliming chamber The heat of the reaction soon becomes sufficiently great to cause part of the sulphur vapour to condense at the bottom of the first chamber, and much of it passes into the second one, where it is deposited as dry flowers of sulphur. With too much air some sulphurous acid would be formed; with too little air some sulphuretted hydrogen would pass off. In the perfect and constant adjustment of the oxygen required by the hydrogen to form vapour of water, is the main key to the success of the process, and the difficulty was to effect this with an ever varying quantity of sulphuretted hydrogen. This difficulty, after three years of experimenting, was overcome in 1886. In decomposing vat waste by lime kiln gases, the sulphuretted hydrogen varies in strength according to the strength of the carbonic acid gas itself, and to the various stages of decomposition of the waste. The sulphuretted hydrogen varies from 1 to 35 per cent. in an irregular manner. The first condition of success was to obtain lime kiln gases containing as constant a percentage of carbonic acid as possible, although from the best worked lime kilns the escaping gases never consist on an average of more than 30 per cent. of carbonic acid, which is accompanied by 70 per cent. of gas, chiefly the nitrogen of the air. A mixture of alkali waste and water, which has been preferably passed through a sieve, is introduced into a series of vessels connected by pipes, and furnished with inlet and outlet ways, and through some or all of such vessels the lime kiln gases are pumped. In the first vessel the carbonic acid is absorbed by any free lime present, with the production of carbonate of lime, and by the sulphide of calcium with the production, in the presence of water, of carbonate of lime and sulphuretted hydrogen. The latter meets with alkali waste in the next vessel, and is absorbed with the production of sulphydrate of calcium, CaH_2S_2. By

Digitized by Google

this twofold absorption, the gases issuing for a time from the last vessel contain neither carbonic acid nor sulphuretted hydrogen; they are allowed to escape after passing through a purifier containing lime or oxide of iron. Thus inert diluent gases, chiefly nitrogen, are allowed to escape. When the gases in a certain vessel contain much sulphuretted hydrogen, because of the carbonic acid acting on the calcium sulphydrate, a workman closes the outlet from the last vessel, and opens another outlet from the intermediate vessel from which the sulphuretted hydrogen is issuing in sufficient strength. The reaction is:

$$CO_2+CaH_2S_2+H_2O=CaCO_3+2H_2S.$$

The gases now contain sufficient sulphuretted hydrogen for profitable treatment and are conducted to a gas holder, whence they can be utilised for making sulphur or sulphuric acid. When the gases become poor in sulphuretted hydrogen the outlet is closed, and having emptied the first vessel or vessels, and filled another or others with a fresh mixture of alkali waste and water, operations are resumed, and so on continuously. The decomposition of the waste is so complete that the water filtered from the residue does not darken a solution of a lead salt. The residue is muddy carbonate of lime, which may be used in black ash furnaces in place of limestone, and also contains bicarbonate and other salts of soda. From 2½ to 3 tons of soda may be saved for every 100 tons of alkali produced. The carbonate of lime may also be used for cement making. The dirty water remaining behind is used with fresh vat waste. The apparatus at the Oldbury works consists of a series of tall cylindrical vessels (seven is a convenient number) suitably furnished with pipes and connections. They are in charge of a man who has to turn the various taps at the right times. The gases are delivered from a lime kiln by means of pipes and powerful carbonic acid pumps. A set of seven cylinders 15ft. high by 6ft. in diameter should suffice to treat the waste from 300 tons of sulphate of soda per week; but there is an advantage in a double set of cylinders, to keep up a constant flow of strong sulphuretted hydrogen. At Oldbury, since November last, vitriol has been regularly made by burning the sulphuretted hydrogen gases in a kiln connected with a complete set of chambers furnished with a Glover's tower and a Gay-Lussac absorbing column. For some weeks past 40 tons per week of sulphuric acid, computed as dry acid SO_3, have been made at the works by burning sulphuretted hydrogen. The acid is free from arsenic, contains but a trace of iron, and is nearly colourless. From first to last, with the exception of fuel to generate steam for pumping carbonic acid, no coal is used. The current cost of working the process is therefore reduced to that of obtaining and pumping carbonic acid from one or more lime kilns.

Sir Frederick Abel, F.R.S., said that he had visited the Oldbury works, and that the process seemed to be a thoroughly practical one.—Mr. J. C. Stevenson, M.P., remarked that after twice visiting the works he had persuaded his partners to take up the process and set up plant at their works.—The Government Alkali Works Inspector stated that the duty of the man who had charge of the taps was simple, as he had to test whether the gas in any vessel was sufficiently rich in sulphuretted hydrogen, merely by the aid of a Bunsen's burner, and noting whether it would or would not burn. He should like to know how much sulphur was collected in proportion to the sulphuretted hydrogen employed.—Mr. Gossage remarked that his father was the discoverer of the decomposition of sulphide of calcium by carbonic acid. Whenever sulphide of sodium can be readily made, there will be no more alkali waste.—Mr. Brock thought that the process decomposed alkali waste profitably, and his company was putting down a plant which would decompose 700 tons of alkali waste per week.—Mr. Alhusen intended shortly to erect a plant at Newcastle to deal with 1000 tons of waste per week.—Mr. F. S. Newall said that some years ago his firm erected kilns just like the one described by Mr. Chance, but did not succeed in recovering sulphur in the dry state.—Professor Dewar, the president of the Society, who occupied the chair, congratulated Mr. Chance on his successful perseverance after having spent £15,000 on failures.

Notes.

THE JUBILEE SHOT.

Considerable expectation centres round the so-called "jubilee" shot which will be fired at Shoeburyness before long. It takes its somewhat fanciful name from the fact that last year it was proposed to fire the new breech loading 9-inch for range, and to try the extreme elevation of 40°. To meet the strain of so great an elevation with a muzzle velocity of over 2000ft.-sec., a suitable carriage was a matter of some difficulty. This, however, has now been surmounted. In anticipation, the range for 40° has been calculated on the following data: Calibre, 9·17in.; weight of projectile, 380lb.; head struck with a radius of two calibres and a muzzle velocity of 2260ft.-sec., though it is said the actual velocity will be greater than this. The following is the result:—

	Niven's method.		Slacci's method.
Range	17,835yds.		17,730yds.
Height of vertex	5,075yds.		5,005yds.
Angle of descent	55° 20′		54° 30′
Final velocity	1,037·5f.s.		1,030·7f.s.

A popular idea of this extraordinary trajectory may be formed by conceiving the gun to be placed at Chamounix, when the projectile would fly far over the summit of Mont Blanc and fall in Italy.

PUBLIC WORKS IN RUSSIA.

In his report on the trade of the district of Taganrog during 1887, Consul Wagstaff states that so far the project of uniting the rivers Volga and Don has remained in abeyance; but as the district of Rostoff and Taganrog have now been definitely annexed to the Don Cossack country, hopes are entertained that the scheme will be realised. The canal would be fifty-three miles long, and it is proposed that vessels allowed to pass through it shall not exceed 210ft. in length, 42ft. in breadth, and 7ft. draught, with a displacement of 500 tons. The construction of a harbour for coasting craft at Taganrog will be commenced this spring. A branch railway to Novorossisk has nearly been completed.

A NEW ANTI-CORROSIVE PAINT.

The smoothness of steel plates, combined with the corroding quality of the material, are leading paint manufacturers to try every possible means for insuring the proper protection of the hulls of vessels and large structures built of mild steel. Some time ago we referred to a proposal of Messrs. M. Holzapfel & Co., of Newcastle-on-Tyne, to rough roll steel plates, in order to provide an adhesive quality; and now we learn that the same firm have, after careful experiments with Chinese soapstone, as a substitute for the metallic pigments usually employed in paints, patented a quick-drying soapstone composition for the inside of steel and iron steamers, ships, bridges, and other structures. Soapstone has for centuries been used in China and Japan for preserving structures built of soft stone, otherwise liable to deterioration by atmospheric influences. When ground it is remarkable for the exceptionable fineness of its grain, and being lighter than metallic pigments, mixed as a paint covers a larger surface than zinc white, red lead, or oxide of iron. In Messrs. M. Holzapfel & Co.'s new composition, soapstone, finely ground, is present in a large proportion, mixed with a quick-drying varnish of great tenacity and hardness. When applied to iron or steel, this paint has large covering capacity, and presents an enamel-like surface of a bright red colour.

THE HEATING OF WIRES BY ELECTRIC CURRENTS.

The extended use of fuses in electric light installations has rendered the question as to the heating of wires by electric currents one of considerable practical importance, and the results of a long series of experiments made in this connection by Mr. W. H. Preece, F.R.S., were recently submitted by him to the Royal Society. The experiments were taken for three temperatures: First, the melting point of shellac, which is 77°C.; second, the point of self luminosity, which for all substances may be taken as 525°C.; third, the fusing point, which is different for the different metals. Mr. Preece experimented with wires varying in thickness from 4 to 40 mils., and comprising the following materials: Copper, aluminium, platinum, German silver, platinoid, iron, tin, lead, and an alloy of tin and lead. For wires varying in diameter between 10 and 40 mils., the current which produces a certain temperature is for each wire given by the product of a constant, and the diameter to the power of $\frac{3}{2}$. For smaller wires than 10 mils. this formula does, however, not hold good, and the current is more nearly proportionate to the diameter. In order to eliminate errors due to the cooling effect of the terminals, the samples experimented upon were 6in. long, being clamped between terminals upon a dry wooden stand; but a second series of experiments was also made for wires stretched between terminals 1¼in. apart, so as to determine the fusing point of short wires such as are used in commercial cut-outs. Mr. Preece arrives at the conclusion that the best metal to use for thin wires is platinum, and for stouter wires, tin. Platinum fuses like wax without explosion or scattering of molten particles, and tin in moderately stout wires behaves in a similar manner. Mr. Preece doubts, however, whether large wires should be used at all for fuses, because, owing to radiation, the surface keeps cool and solid, while the centre is liquefied. The wire then bursts with an explosion, and incandescent particles are scattered in all directions with considerable energy.

KEEP'S TESTS FOR FOUNDRY IRON.

A paper of more than usual interest is announced to be read at the next meeting of the South Staffordshire Institute of Iron and Steel Works Managers, to be held at Dudley, on the 24th inst. The title of the paper is "Keep's tests for foundry iron—a proposed standard series of tests for pig iron for foundry purposes." Mr. W. J. Keep, the author of the paper, is superintendent of the Michigan Stove Company, Detroit, Michigan, U.S.A. At these works 70 tons of iron is daily used for stove plates, and as the result of a good many years' experience, systematical tests have been devised which give every satisfaction, and which have recently been adopted by a number of American firms engaged in the sale or use of foundry pig. Mr. Keep's paper has been revised, and will be communicated by Mr. Thomas Turner, Assoc.R.S.M., lecturer on metallurgy at Mason College, who has himself devoted considerable attention to foundry iron; and it is anticipated that, even where these tests are not adopted, considerable interest will be taken in the new methods of testing introduced by Mr. Keep.

EXPLOSIVES.

In the current number of the Proceedings of the R.A. Institution, a further instalment is given of the valuable "Dictionary of Explosives," in process of compilation by Major J. P. Cundill, one of H.M. Inspectors of Explosives. This instalment deals with nitro-compounds containing nitro-glycerine, and forms the fourth class or division into which he has divided his subject. Before detailing in alphabetical order, and explaining the numerous compounds that come under this head, he has made a few introductory remarks of value; *inter alia*, he gives an interesting sketch of the progress of the manufacture and commercial use of dynamite. Nitro-glycerine was discovered by A. Sobrero, in the laboratory of Pelouze, in 1847; but for many years no practical use was made of it, except to a very limited extent, as a medicine, until between 1860 and 1863 Alfred Nobel, a Swedish engineer, established factories on the Continent for its manufacture on a commercial scale as a blasting agent, and a further step was made in its development when he discovered that by means of the initial explosion of a detonator, he could elicit its enormous energy. But during the next few years a series of disastrous accidents, due to liquid nitro-glycerine, led to public reprobation of the compound, and Sweden, Belgium, and England totally prohibited its use. Nobel, however, continued his investigations, and in 1867 he patented an invention which placed dynamite among recognised articles of commerce in this country. He caused the nitro-glycerine to be absorbed in porous unexplosive substances—such as charcoal—whereby it became insensible to shocks, and could be burned over a fire without exploding, while if fired by a detonator its full power would be developed. "Dynamite" is now used as the genuine title for a vast number of nitro-glycerine explosives, known under various distinguishing or fancy names.

THE DOTY LIGHT.

The *Times* states that a very useful and cheap self generating light for illuminating workshops and for enabling outdoor operations to be carried on at night has just been perfected by Captain Doty, who will be remembered as having solved the problem of employing mineral oils in lighthouse illumination. The Doty light, which is self contained and portable, consists of a galvanised iron cylinder 2ft. high and 18in. diam., which contains a supply of paraffin or other mineral oil. Pressure is brought on the top of the oil by means of an air pump attached to the cylinder, and the oil is thus forced up a tube which reaches nearly to the bottom of the oil supply. This tube is placed outside the top of the cylinder in a spiral form, and the end is continued downwards, so that the orifice of the tube is in the centre of the vertical coil, and constitutes the burner. The lamp is lighted by first heating the coil by a small oil flame to the temperature necessary for the vaporisation of the oil. When this point is reached, which is in three or four minutes, the oil is turned on, and upon entering the coil is at once vaporised and burnt as a gas, giving a brilliant flame some 3ft. high. As the flame originates at the bottom of the coil and passes up through its centre it keeps the coil hot, and the conversion of the oil into gas goes on continuously. The working air pressure is from 10lb. to 15lb. per square inch, and a 500 c.p. light, it is said, will burn for thirteen hours with one charge of oil, and at a cost of less than 6d. per hour. The air pressure requires renewing about every two and a half hours. A demonstration of the Doty light took place on the 8th inst. at Messrs. F. Braby & Co.'s works at Deptford, when two of the lights were shown to amply illuminate a store 200ft. long by 40ft. wide. It was found possible to read a newspaper at a distance of 130ft. from one of the lights, and the demonstration was in every way a success.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

2nd March, 1888.

3183. Stanley, D. A. — Air compressor.
3186. Maltby-Newton, C. — Gas engine.
3206. Bernhardt, G. — Spinning machines.
3211. Skinner, H. A. — Double acting pumps.
3212. Briggs, I. — Spinning frames.
3216. Oldroyd, J. W. — Steam boilers.
3226. Davy, C. — Bloom shearing machines.
3232. Thompson, W. P. — Dyeing fabrics (*Doulceron and Van Meerbeeck*).
3233. Myers, F. — Type writing machines.
3237. Williams, S. de la G. — Lime kilns.
3248. Jones, C. W. — Spinning machinery.

3rd March, 1888.

3253. Nussey & Haskard — Warp knitting machines.
3261. Woollason, W. — Threshing machines.
3265. Moorhouse, W. H. — Jacquard mechanism for looms.
3266. Dorman, W. H. — Circular knitting machines.
3270. Winder, R. — Type composing machines.
3285. Oliver, T. — Winding yarn.
3288-9-90-91-92. Burkhardt and Jackson — Forming hollow spheroidal bodies from metal tubes.
3296. Thompson, W. H., and others — Pulverising machine.
3311. Davis & Howard — Sewing machines.
3313. Bollmann, L. — Sewing machines.
3314. Skaife, W. — Riveted joints.
3326. Breeden & Breeden — Screw cutting lathes.

5th March, 1888.

3337. Windrath & Hausmann — Looms.
3339. Evans & Hall — Generating steam.
3340. Bottomley & Townsend — Pickers for looms.
3342. Fairweather, W. — Copying press (*Schwing*).
3345. Holt & Gould — Potato digging machines.
3346. Fisher, H. A. — Twist lace machines.
3349. Wilkinson, F. — Carding engines.
3353. Fry & Fry — Paddle wheels.
3356. Low, R. — Spinning machinery.
3359. Law, E. F. — Type writers.
3367. Wise, W. L. — Centrifugal machines (*Burmeister & Maskin-og-Skibsbyggeri*).
3368. Turnill, A. C. — Thrashing and seed rubbing machine.
3370. Richardson, W. — Grinding the teeth of the "cards" employed in carding engines.
3381. Rogers, H. — Axle boxes.
3383. Krell, O. — Gun carriages.
3384. Mudd, T. — Steam hammers.
3388. Poore & Storey — Vessels constructed to travel under water.

6th March, 1888.

3397. Page, W. A. — Road sweeping and collecting machine.
3406. Walker, A. B. — Two wheeled road carriages.
3409. Holgate, J. B. — Apparatus for conveying granular substances.
3410. Hall, J. F. — Manufacture of iron or steel.
3414. Thompson, W. — Shedding motions of looms.
3419. Brown, G. — Kilns for burning bricks.
3420. Eves, J. V. — Flyer spinning of fibres.
3425. Frisbee, G. — Crushing mills.
3427. McGhee & Burt — Gas motor engines.
3429. Lawrie, J. G. — Corrugated furnaces.
3432. Gutman, J. — Sewing machines.
3439. Pearson, M. H., & others — Punching and eyeletting machines.
3445. Röell, C. F. A. — Pleating fabrics.
3447. Gillies, D. — Axle for mortar mills.
3449. Justice, P. M. — Railway switches (*Isbell*).
3450. Paul, E. — Pumps.
3452. Catchpole, A. — Generating steam.
3454. Murrie, J. — Condensers for steam engines.
3457. Shepherd, J. W., & ors. — Winding yarn.
3465. Watson, T. — Damping yarns in looms.
3473. Wawn, C. — Travelling cranes.
3474. Edwards, E. — Starting apparatus for carriages (*Feenel*).

7th March, 1888.

3479. Ashworth, H. — Mules.
3481. Latouche, J. A. C. de — Mounting and working guns.
3488. Orr & Brown — Pointing and closing the ends of metal tubes.
3489. Dawson, D. R. — Sewing machines.
3490. Mycock, W. — Dyeing apparatus.
3491. Bradbury, J. — Weighing machines.
3503. Watkin, H. S. S. — Firing guns.
3508. Thompson, W. P. — Cable coasters (*Van Zandt*).
3518. Murrie, J. — Pumping engines.
3531. Taylor, W. H., & others — Loom temples.
3541. Pastor, F. — Forging bolt heads.
3542. Watson, C. T. — Machines for printing cards.
3544. Bischoff, M. — Cutting screw threads.
3545. Greenway, G. H. — Sand washing and elevating machine.
3546. Rollason & Hamilton — Gas engines.

8th March, 1888.

18031. Hignette, J. J. — Grinding mill. (Ante-dated 18th October, 1887. Under International Convention.)
3554. Smith, D. — Moulding and folding sheet metal.
3556. Taylor, J. — Consuming smoke.
3559. Mycock, J. — Dyeing machines.
3561. Sharples, G. B. — Smoke consuming apparatus.
3569. Wilson, J. W. — Steering ships.
3570. Philip, J. R. — Centrifugal machines.
3573. Bamford & Wild — Manufacture of velvets.
3576. Gibson, J. — High speed gearing.
3577. Clegg, G., & others — Twisting yarn.
3582. Dealy, T. — Motors.
3583. Holroyd & Wilson — Kilns for heating pottery.
3585. Longbottom, W. — Picking motion for looms.
3586. Longbottom, W. — Shuttle boxes for looms.
3587. Burtscheidt, G. — Weaving pile fabrics.
3597. Britain, W. — Centrifugal pumps.
3606. Cooper, R., & others — Dyeing fibrous substances.
3609. Johnson, J. Y. — Water meters (*La Société Fritz Perret et Cie*).

ELECTRICITY.

2nd March, 1888.

3215. Oldroyd J. W. — Electric incandescent lamps.
3223. Kingsland, W. — Secondary batteries.
3230. Allsop, F. C. — Electrical tramways.
3235. Miot, G. — Dynamo-electric machines.
3246. Walker, F. — Electrical lamp.

3rd March, 1888.

3286. Addenbrooke, G. L. — Electrical measuring instruments.
3303. Leigh, H. H. — Registering the consumption of electric energy (*Clerc*).
3312. Tyer, E. — Voltaic batteries.
3328. Langdon-Davies, C. — Commutators.

5th March, 1888.

18030. Lebiez & Verchère — Thermo-electric batteries. (Ante-dated 8th November, 1887. Under International Convention.)
3369. Watt, A. — Zinc ores.

6th March, 1888.

3456. Winnall, W. H. — Electric bells.

7th March, 1888.

3483. Schmidt, F. T. — Electrical switches.
3498. Parker, T. — Dynamo-electric machines.
3504. Oldfield, J. — Multiple electric communication.
3515. Collet, H. — Telephonic apparatus.
3517. Disher, R. — Primary batteries.
3535. Fitch, W. B. — Electric conductors.

8th March, 1888.

3550. Thompson, N. G. — Electrical battery.
3571. Laurie, T. — Telephonic transmitters.
3590. Statter, J. G — Electrical transformers.
3593. Walker, R. — Electric batteries.
3614. Ferranti, S. Z. de — Dynamo-electrical machines.
3618. Saunders & Brown — Fire alarm telegraphs.

CHEMISTRY.

2nd March, 1888.

3179. Bowen, E. — By-products of gas manufactures.
3182. Chance & Chance — Sulphuretted hydrogen.
3193. Thatcher, E. — Brewers' "finings."
3218. Gossage & Mathieson — Sulphide of sodium.
3228. Bunn, P. C. — Extracting gold.

3rd March, 1888.

3310. Byrom, W. A. — Making charcoal from peat.
3317. Schmidt, V. — Metallic alloy.

5th March, 1888.

3374. Hessel, C. — Zinc white.
3378. Lebedeff & Hughes — Treatment of metallic ores.

6th March, 1888.

3428. Green, H. — Treating ammoniacal liquor.
3476. Von Ehrenwalten and Fabricius — Production of gas.

7th March, 1888.

3495. McDougall, A. — Manufacture of gas.
3510. Manbrè, E. — Making alcohol.
3530. Brins Oxygen Company and Goble — Carbonated oxygen water.
3547. Brin, L. Q. — Aluminium bronze.
3548. Brin, L. Q. — Plating iron with aluminium.
3549. Brin, L. Q. — Alloys of aluminium.

8th March, 1888.

3579. Geary, G. J. — Sulphide of zinc (*Keiller*).
3601. Cunningham, A. B. — Sodium and potassium.
3602. Cunningham, A. B. — Aluminium.
3613. Jones, F. F. — Sulphate of iron.

MISCELLANEOUS.

2nd March, 1888.

3180. Birch, W. — Stretching fabrics.
3187. Rose, W. — Chain cable.
3188. Hartnell, W. — Treating sheets of iron after tinning.
3192. Dyson, R. — Supporting rails in their chairs.
3195. Emmett, H. — Door places for hoists.
3198. Norcliffe & Jessop — Steaming seal skin fabrics.
3201. Orr & Brown — Producing patterns upon metal.
3202. Temple, W. — Drying bricks.
3203. Jones, J. — Forging & re-sharpening chisels.
3204. Mitchell, A. — Shuttle for weaving (*Dolbey*).
3220. Taylor, E. K. — Tricycles.
3221. Palmer, T. N. — Mitreing printers' rules (*Golding*).
3222. Parkes & McWatt — Cut nails.
3224. Parker, C. E. S. — Couplings for carriages.
3225. Shearme & Morris — Measuring liquids.
3227. Smith & Smith — Locks and bolts.
3231. Boult, A. J. — Packing cases (*Lancha*).
3238. Hopkinson & Hopkinson — Stop cocks.
3240. Pearce, H. T. — Horseshoes.
3242. Varley, J. J. — Stoppering bottles.
3243. Herrmann, M. — Lamp glasses.
3249. Stokes, W. — Gulley traps.

3rd March, 1888.

3254. Graham, H. J. — Bottles.
3255. Wheatley, W. T. — Cement.
3256. Hobson, A. H. — Treatment of bones.
3262. Ogg, J. — Dressing stone.
3263. Rylands, D. — Bottles.
3267. Billington & Newton — Lubricators.
3271. Davies & Fraser — Stuffing boxes.
3275. Leather, J. P. — Regulating the pressure of gas.
3281. Roeckner, C. H., and others — Refining paper pulp.
3282. Buckton, H. — Regulating the pressure of water in mains.
3287. Fairclough, G. — Lubricator.
3293. Loftus & Angier — Signal lamps for ships.
3294. Hawkins & Stacey — Hydrocarbon lamps.
3297. Clayton & Gresham — Warming railway carriages by steam.
3299. Kelly, W. P. — Lubrication.
3302. Reynolds & Hibbard — Lamp.
3306. Carter & Aynsley — Spring hinges.
3309. Corcoran, P. — Dressing stone.
3316. Stark, W. F. — Manufacture of candles.
3318. Bayer & Lease — Tricycles.
3319. Héroux, J. — Gas extinguisher.
3320. Surprenant, L. — Nut lock.
3323. Palmer, T. N. — Mitreing printers' rules (*Golding*)
3327. Griffiths, A. H. — Lamps.

5th March, 1888.

3329. Walsh, J. — An improved lens.
3347. Matthews, S. — Water gauges for steam boilers.
3373. Warner, W. J. — Dry gas meters.
3382. Redfern, G. F. — Fixing railway rails to sleepers (*Coblyn*).

6th March, 1888.

3391. Vinton, J. H. — Ratchet drills.
3394. Harrison, W. M. — Fire extinguishers.
3395. Whittaker, R. — Clip for holding rolled material.
3405. Low, W. — Drying fibres.
3407. MacLeod, A. C. — Projectiles.
3408. Redwood, E. G. — Wood finishers.
3411. Haill, J. — Brake.
3415. Wilson, R. — Couplings for rolling stock.
3423. Burtonshaw, T. — Tar burners.

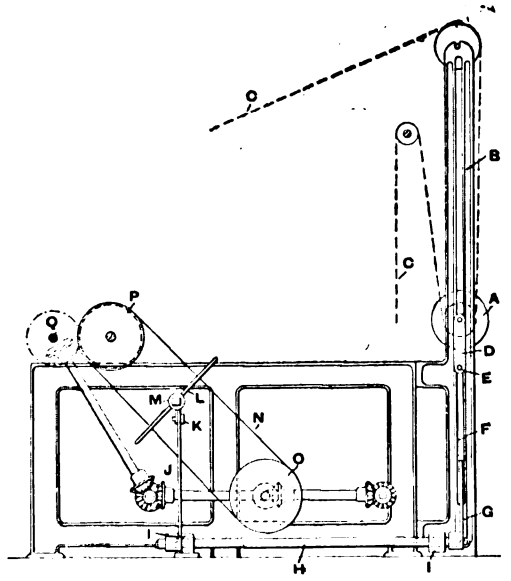
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Boiler Furnaces.—*J. Platt, Sheffield.*—This invention is applicable to various types of furnace, but more particularly to the furnaces of Cornish boilers. An air box is formed in the brick work of the fire bridge, or is constructed of fire clay or metal faced with brick. An opening is made in the box for the admission of a pipe to the rear of the bridge. At the bottom of the bridge below the fire bars is another pipe whose mouth comes through the front of the bridge. This pipe is carried for some distance on the bottom of the flue tube, and its direction is then reversed towards the bridge, where it is connected with the opening in the air box. In the bottom of the flue tube underneath the fire bars are a number of plates lying horizontally above the mouth of the pipe in the bottom of the bridge, and protecting it from being choked up with ashes. These plates are provided with longitudinal ribs on the under side, and extend from the front of the bridge to the front of the boiler, thus forming air spaces which may be provided with valves for the regulation of the admission of air. When the boiler is at work the plates below the grate bars become heated by the cinders falling on them, and the air admitted into the spaces below the ash plate becomes heated in its passage towards the mouth of the air pipe in the bottom of the fire bridge; in passing through this pipe the air is further heated as it approaches the air box, whence it is discharged through the orifices in the cover bricks at the top of the fire bridge. In its heated and rarefied state it intermingles with the gases and other products, thereby contributing to a more perfect combustion. The inventor makes two claims for the parts constituting the air box and its pipes for the purposes described.—No. 5676. April 19th, 1887. 8*d.*

Manufacture of Steel.—*B. H. Thwaite, Liverpool, and J. Noble, Middlesbrough.*—This invention introduces certain improvements into the process described in Patent No. 11972 of 1886, granted to B. H. Thwaite. The molten metal from the blast furnace is run direct to a receiver. After a sufficient quantity is accumulated, it is tapped into the ladle, which runs on rails on an upper floor. This upper floor is built at such a height above the open hearth furnace as to be level with the upper end of a Thwaite vertical pneumatic converter placed on the centre of the furnace roof. Open hearth recuperator vessels are placed on this upper floor. The melted pig is run from the ladle into the Thwaite converter, in its course through which it is partially converted by the air blast. The bath of the open hearth furnace is made shallow, so that a large surface of metal is exposed. When phosphoric pig iron is employed, a preliminary basic open hearth and inclined furnace is substituted for the basic cupola. The inclined hearth furnace has several levels, on which the pig iron can be rapidly charged and melted. A finely ground limestone is there added to the metal, in order to increase the basic character of the slag. A recuperative arrangement is provided in this inclined furnace for the removal of the phosphoric element; and a second furnace of silicious material



afterwards receives the metal in its pure state. The inventors specify several arrangements of plant for carrying out this process, one of which is illustrated in vertical section in the accompanying diagram. The furnace is made circular in plan; its under side is surrounded by a casing A, enclosing an air space B. This air space is connected with another at C, which in its turn is connected to the air reversing valve D, so that the heat radiated from the side of the furnace is utilised by being re-added to the internal heat of the furnace. The tapping spout is shown at E, the Thwaite converter at F, the cupola at G, and the receiver at H. The upper part of the converter communicates with the gas supply flue I, so that it can be heated to a high temperature before the metal is tapped from the receiver H. The air to support the combustion of the gaseous fuel in the converter passes through the metal ingress J, which can be entirely covered with a fire clay plug K. The reversing valve arrangement is placed on the upper floor; L is the air valve connected to the air recuperator vessel M, and the gas valve N communicates with the gas recuperator O. The valves are connected to the chimney flue junction P by means of the lined flues Q. The inventors make five claims for the process and the plant described.—No. 16497. December 1st, 1887. 1*s.* 1*d.*

Hot Air Engines.—*R. L. Howard, E. Howard, & R. S. Lloyd, London.*—In some hot air engines, such as the Ryder engine, Patent No. 3404 of 1875, the lower part of the heater is exposed to the direct heat of the fire, and consequently wears out much sooner than the upper part. According to this invention, the lower part is made of cheaper cast iron, and is bolted on to the rest of the heater. The removal of the worn out parts is thus facilitated. In another modification, the door of the fire box is made sufficiently large to effect the removal of the entire heater. The door is placed in the front, and the smoke outlet at the back is constructed in such a manner as to act as a hand hole for reaching the parts to be detached. An annular baffler is arranged underneath the annular bottom of the heater, in order to protect the heater from the direct heat. The inventors make two claims for making the heater in two parts and for the annular baffler.—No. 4692. March 29th, 1887. 8*d.*

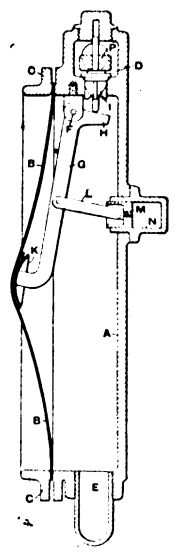
Sizing, Drying, and Warping Machines.—*E. Brook, Huddersfield, and J. Vickerman, Mirfield, Yorkshire.*—In the ordinary machines for combining the three processes of sizing, drying, and warping, the increasing diameter of the coil of threads wound in the warping mill tends to increase the tension on the threads as they come from the letting off rollers in the drying machine. The object of this invention is to provide an automatic regulator of the tension. The accompanying figure illustrates an end elevation of one of the two modifications of the improved apparatus. The essential feature is the application of a loosely mounted rising and falling roller A, and the frame work B for guiding its motions. Its position is dependent on the tension of the threads C, which in their passage from the sizing machine to the warping mill are caused to pass under and support the roller in the manner shown in the figure. The spindle D is connected by the arms and cross bar E and rod F to a lever arm G which projects from a rocking shaft H. Another arm J fixed to the rocking shaft is linked to the belt shipper L, which works on a guide rod M. The belt N passes partly round

a pair of slightly conical pulleys O P. The small end of one pulley is arranged opposite the large end of the other, so that as the belt is shifted from the large end of the driving pulley towards the large end of the driven pulley by the increased tension in the threads, the warping mill is caused to run somewhat slower. When one section has been wound on the warping mill and another section is commenced, the tension on the threads C is least, and the mill may not take the threads up as fast as they are let off from the drying machine. This defect is immediately rectified by the roller falling by the action of gravity. Afterwards the roller in its descent drags the belt shipper and belt towards the large end of the driving pulley, as described. In the second modification the object is attained simply by the use of a weighted roller which is suspended by the threads. This method is only applicable where there is very little variation of tension. The inventors make two claims, one for each modification.—No. 4591. March 28th, 1887. 8*d.*

Magazine Guns.—*A. J. Boult, London.* (*M. Hartley, New York.*)—This invention relates to the Martini-Henry type of arms, in which a breech block pivoted at its rear end in the frame swings downwards and backward to open the breech. In the Patent No. 9796 of 1887 the present inventor described a gun in which the breech block was made in two parts, both swinging on the same pivot, with a passage between them for conducting the cartridges from the magazine in the rear stock to the chamber. According to this invention, the breech block is made in a single piece, with a longitudinal opening through it, which forms a continuation of the magazine tube, and serves to conduct the cartridges to the chamber. Four claims are made. —No. 17384. December 17th, 1887. 8*d.*



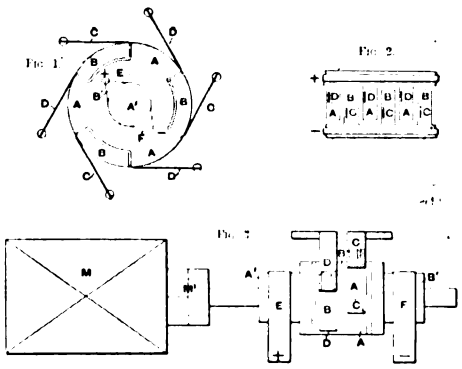
Wood Working Machinery.—*A. Kerr & R. Kerr, Glengarnock, Ayr.*—The wood to be operated on is fastened between two adjustable sockets, which can slide along slots in the table of the machine. Two side standards are connected at the top by a bridge frame, which is grooved vertically to hold a sliding piece which carries the tool. The tool holder is vertically adjustable by means of a screw, so as to adapt it to various work. Two feet attached to a transverse bar on the tool holder slide over the surface of templates fixed to the side of the table. The shape of the template causes the tool holder to slide up and down in the groove in the bridge frame, while gravity effects its descent. The course pursued by the knife is thus determined and the figure cut from the wood can be varied indefinitely by the employment of templates of different shapes. Three claims are made.—No. 15626. November 15th, 1887. 6*d.*

Carding Engines.—*W. Knowles, Bolton.*—The revolving flats are constructed, according to this invention, so as to clean and improve the fibre more effectually. The endless lattice of revolving flats is divided into two entirely different sections. The first section is mounted on pulleys and guided over the bend in the usual manner, and is formed of flats of coarse open filleting. When these flats are passing the under side of the bottom pulley, near the taker in, they are guided in a parallel line to facilitate the stripping performed by a revolving brush or filleted roller. The removed strippings are cleared from the revolving brush by another one, which delivers them to the taker in. The strippings are then subjected to the usual operation performed by the taker in, and the dirt is driven by its centrifugal force into the fly space. Any imperfections which are not thus arrested will be caught again by the first section of the flats, and the process will be repeated until all the dirt has been deposited in the fly space. The second section of the flats is constructed and mounted in the usual way, and is divided on the upper side of the carding cylinder by a plate which extends across the cylinder from side to side. A filleting of fine wire is fixed on the flats, and is calculated to act on the previously purified fleece in a more effective manner. The first set of flats may be driven at a greater speed than the finishing flats. The inventor makes three claims for this arrangement of flats.—No. 5416. April 14th, 1887. 8*d.*

Wood Planing Machines.—*T. N. Robinson, Rochdale.*—This invention is more particularly applicable to hand planing machines, in which a horizontal cutter block is supported between a pair of bearings. It may also be applied to machines which are provided with a self acting feed. The aim is to readily adapt such machines to cut straight, curved, or circular mouldings without interfering with its ordinary uses. An adjustable table is fitted in guides on one end of the machine, and in the end of the cutter spindle a hole is bored, preferably of taper form. The hole has a screw thread at one end, and any number of different sized spindles may be fitted into it. These small auxiliary spindles carry cutter blocks on which moulding cutters are secured. In some cases the wood to be operated on is placed below, and in other cases above, the cutter spindle. In the former case an adjustable fence is fixed to the table, together with the necessary spring rollers for steadying the timber. A hole in the table permits it to be raised above the small cutter spindle for cutting mouldings with a fly cutter. In this case a piece of hard wood is fitted into the hole in order to form a support for the cutter. When the machine has been set in motion the table is gradually lowered until the cutter has cut through the plug of wood, and projects far enough through it to cut the desired moulding. The inventor makes two claims for the combination of the ordinary surfacing cutters with the overhanging moulding or fly cutters, and with the adjustable slotted table and filling up piece as described.—No. 5100. April 6th, 1887. 8*d.*

Mangle Racks for Platen Printing Machines.—*T. Coulthard & J. Bradshaw, Preston.*—This invention relates to that class of reciprocating toothed racks called mangle racks, in which the axis of motion of the driving pinion is fixed. Arrangements are made by which the rack when shifting from side to side at the end of its traverse may be caused to move bodily at right angles to the line of its path. The rack is mounted so that it can slide upon two or more transverse guide rods, which are arranged at suitable distances from each other, and fixed to the plate upon which the rack is carried. This arrangement permits of a considerable acceleration of the reciprocating movement of the racks. The inventors claim the combination of reciprocating toothed racks with transverse slides or guide rods arranged as described.—No. 5057. April 5th, 1887. 8*d.*

Gas Engines.—*C. G. Beechy, Liverpool.*—The accompanying figure illustrates the inventor's design for a gas bag for regulating the supply of gas to the engine. The objects aimed at in this arrangement are to prevent fluctuation of the pressure of the gas in the mains, and to automatically close the inlet valve in the event of the bursting of the bag. One side of the cast iron case A is provided with a flexible diaphragm B, which is secured in its place by the ring C. The gas enters at D, and proceeds to the engine through the opening E. A lever G, wholly inside the box, is pivoted at the point F, and its lower end is formed so as to press against the diaphragm. The tail H actuates the entry valve I, and a lever L attached to the middle of G is connected with the piston M, which works in the cylinder N. The weight P is placed on the valve I, and is made sufficiently



heavy to overcome the weight of the lever G when the pressure of the diaphragm is released. When the engine starts, the box will be full of gas, the diaphragm will be forced outwards, the inlet valve I closed, and the lower end of the lever G will press against the diaphragm, as shown in the figure. The engine then draws the gas through the outlet E, and the diaphragm retracts and carries with it the end of the lever G. The tail H is caused to open the gas inlet valve I, and more gas enters the box. The dash pot N prevents the lever G from returning quickly, so that the diaphragm on again becoming distended by the entry of the gas, parts from the lever for a time. The counteracting actions of the diaphragm, dash pot, and the pressure of the entering gas reduces the fluctuation of the supply to a minimum, and the pressure in the main is hardly disturbed at all. In the event of the gas bag bursting, or of the engine stopping while the gas cock is open, the inlet valve will automatically close by the weight P overcoming the power of the lever G. The inventor makes three claims for the arrangement and construction of the gas bag, as described above.—No. 4160. March 19th, 1887. 8*d.*

Portable Boiler and Centrifugal Pump.—*Tangyes, Limited, Birmingham, and T. Jefferies, Handsworth, Staffordshire.*—The object of this invention is to combine a portable boiler with a centrifugal pump and engine, in such a manner that a complete balance shall be effected, and that the pump shall be kept free from the dust due to the firing of the furnace. A frame of wrought iron is connected to the fire box and extends from side to side between the pairs of wheels. The engine bed of cast iron is secured on this base; at one side is placed the steam engine and on the other the centrifugal pump, and the spindle of the pump is coupled to the crank shaft of the engine. The pump is so arranged that it can be turned in several directions to meet the varied requirements of the suction and delivery pipes, and when the pump is not in use, the coupling can be unloosed and the engine can be employed for other work. A fly wheel is placed on the outer side of the shaft in a convenient position for being surrounded with a driving belt. The inventors make one claim for the arrangement.—No. 32220. March 2nd, 1887. 6*d.*

Welding the Ends of Tubes.—*J. P. Kennedy & E. S. T. Kennedy, New York.*—By the machine here invented the end of the tube to be closed is heated to a working heat, and afterwards fed forward and rotated whilst it is subjected to the swaging action of a pair of conical dies. After a conical end is formed, it is re-heated and slid upon a mandrel with a hemispherical end. A die with a concave rounded recess descends upon the end supported on the mandrel, and the tube end is welded and swaged upon itself without seam or joint. The inventors make eighteen claims for the process, the machine, and the tube as an article of manufacture.—No. 11673. August 27th, 1887. 8*d.*

ELECTRICITY.

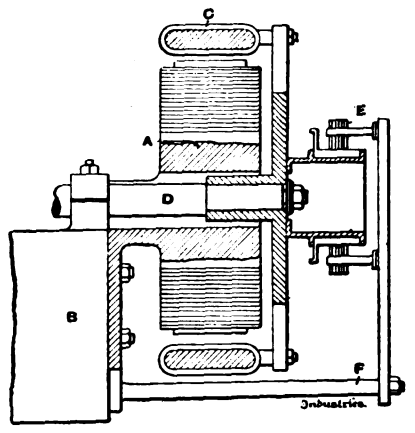
Electrical Transformer.—*M. Immisch, London.*—In converting alternating currents into continuous ones the inventor employs a primary conductor, through which the alternating current passes, and which is surrounded by a number of secondary conductors, in which induction takes place. The inner end of each secondary conductor is connected to a brush, and the outer end of each to another brush, and each of these brushes rests on a hub connected to a separate series of commutator segments, the two series being arranged alternately in a

circular form, so as to fit each other. The brushes thus serve to convey the alternating currents induced in the secondary conductors to the commutator segments. By reference to the accompanying diagrams this arrangement will be better understood. Fig. 1 is an elevation showing the commutator segments, brushes, and collectors; Fig. 2 is a plan view of the same, opened out; and Fig. 3 is a plan view of the general arrangement. The commutator is formed in this case of three segments in the two series A and B. The brushes C and D are similarly divided into two series. A^1 is the hub common to all the A segments, and a brush or stirrup E rests on it; while B^1 is common to the B segments, and supports the stirrup F. The commutator is applied directly to the spindle of the motor M. Part of the alternating current is led to the motor through its own commutator M^1, and as the commutator of the transformer is mounted on its spindle, the movement of the motor will be transmitted to it. The alternating current passes through the primary wire of an induction coil, and thus induces a current in the secondary wires, the ends of which are connected either to the brushes A and B or to the brushes E and F. The secondary wires of the induction coil may all be connected to a switch, so as to enable them to be placed more or less in parallel for the purpose of varying the current. A suitable switch is also provided for putting the transformer in and out of action. In the case where the induced current is led to the brushes E and F, the continuous current will be taken off by the brushes A and B, and *vice versa*. Instead of mounting the transformer directly upon the motor spindle, it may be driven from its spindle by suitable gearing at a different speed from the motor, and all that is necessary is that the number of impulses per unit of time in the motor shall correspond with the number of changes in the commutator. The inventor makes one claim for the construction of this transformer.—No. 831. January 19th, 1887. 8*d.*

Electric Switch.—*B. Egger, Vienna.*—This switch is intended for use in combination with electric conductors and incandescent lamp holders. A hand lever and a contact lever are placed upon one axis, so that they may be easily turned. When the circuit is interrupted, they are pressed against stop pins, which are placed in a definite angular position by a spring already under tension. On turning the hand lever in one direction, it will pass into a position in line with the contact lever, which continues to bear against the stop pin. The spring is under the greatest tension in this straight position, and is ready for the succeeding operation. When this dead point is exceeded by the further movement of the lever, and when the angle between the two levers has become less than 180°, the spring contracts and moves the contact lever away from the stop pin to another pin, which has a contact spring attached to it, and the circuit is thus closed. The same operations take place during the

Digitized by Google

return movement for the purpose of breaking the circuit. The sudden and exact making and breaking takes place whether the movement of the hand lever is slow or rapid. If the switch is a large one, it is arranged that a rod which can slide to and fro shall act upon a lever by means of an arm slotted laterally, and impart to it the required motion. The inventor makes one claim for the construction of the switch, as described.—No. 5092. April 5th, 1887. 8*d.*



INDICATING THE SPEED OF SHAFTS.—*J. S. Gisborne, London.*—The object of this invention is to indicate on the bridge of a ship the direction and speed of revolution of the engine shaft, by means of an electric connection. A small spindle is mounted horizontally on suitable frame work, close to the main shaft of the engines. At either end of the spindle is fixed a double ended lever, carrying a friction roller at one end and an electrical contact piece at the other. The friction rollers are intended to gear with an eccentric placed on the engine shaft. A pawl is fitted at the end of each lever; one of them causes one of the levers to be depressed when the shaft revolves in one direction, and the other causes the second lever to be raised during the opposite direction of revolution. Each of the contacts completes an electrical circuit, and the consequent current is transmitted to the bridge, where there are registering and recording instruments of any approved form. Five claims are made.—No. 17575. December 21st, 1887. 8*d.*

GENERATING ELECTRICITY FROM HEAT.—*P. M. Justice, London. (E. G. Acheson, Pittsburgh, Pennsylvania.)*—This invention is based upon the discovery that if a magnetic whirl is produced about an electric conductor which is traversed by currents of heat, an electric current will be generated in the conductor at each making and destroying of the magnetic whirl. In order to make use of this discovery in a practical manner for the generation of electricity, the inventor arranges a hollow cylindrical core wound with a series of convolutions of insulated wire. The terminals are connected to the primary circuit, which supplies the intermittent current. Through the core and coil is passed the conductor or conductors which form the converting or generating coil. The terminals of this second coil are connected to the working circuit, and suitable means are applied for inducing a current of heat in one part of it. It is found most convenient to have two magnetic whirls round the conductor, with the directions of the lines of force in opposition; by placing the source of heat between the whirls so that the heat shall pass from a central point in opposite directions, the lines of force of the whirls will be such as to convert the heat into electric currents in the same direction. There are several other ways mentioned in the specification of carrying out this discovery, but the above sufficiently indicates the nature of the invention. Six claims are made for this method of converting heat into electricity.—No. 17837. December 28th, 1887. 8*d.*

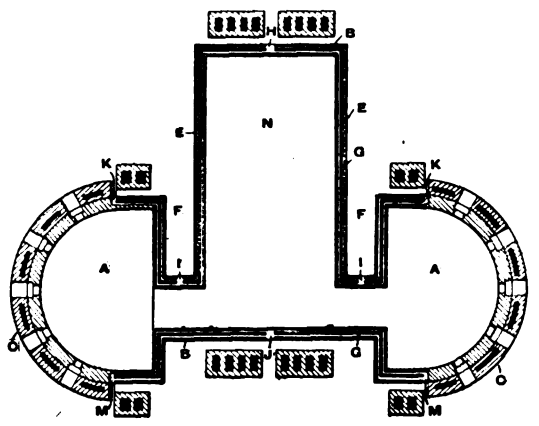
DYNAMOS.—*J. Hopkinson, London, and E. Hopkinson, Manchester.*—This invention relates more particularly to that class of dynamos in which there is more than one electric field. The object is to secure abundant room for the copper conductor of the armature, and to avoid as far as possible any undue variation of the magnetism as the armature revolves. The best form of machine for this purpose is that in which the lines of magnetic force are parallel to the axis of rotation of the armature. The armature consists of a series of bobbins having iron cores composed of thin plates placed tangentially to their direction of motion. The cores have preferably polar extensions for rendering the field easier to produce. The bobbins rest on the outside of a wheel, whose radiating arms fit between the cores of the armature. The bobbins are bound in by rings which slip over their ends. The outer ends of the magnets are attached to cast iron rings, and the wrought iron cores are let some distance into the cast iron. However, the magnets may sometimes be fitted with cast iron pole pieces, and in this case the wrought iron is let into the cast iron. To obviate the danger of accidents from the high speed of revolution, a number of guards are placed at a small distance from the binding rings. As soon as these rings begin to stretch they come in contact with the guards, which immediately act as a brake. The rings are secured by screws to snugs on the wheels of the armature, and the plates of the armature cores may be secured together by bolts, provided that these are placed in such a manner that they shall not close electrical circuits around the lines of force. The inventors make eight claims for this improved dynamo.—No. 4322. March 22nd, 1887. 11*d.*

GENERATION AND DISTRIBUTION OF ELECTRICITY.—*R. Dick and R. Kennedy, Glasgow.*—By these improvements a main constant current is transformed locally into a secondary current of any desired strength in a secondary circuit in which the translating devices are placed, and a constant electromotive force is obtained at the terminals of the secondary circuit while there is a variable current along its length. A combination of a dynamo with an electromotor is made use of to produce this effect. The motor field magnets and the dynamo field magnets form the frame work of the machine; the motor armature and commutator are fixed at one end of a longitudinal shaft, and the generator armature and commutator are secured to its other end. The main conductor is coiled in series along the upper field magnets of both the motor and generator, and is also wound in series along the lower field magnets of the same; thence it passes to the terminal end of the brushes on the commutator of the motor, and the circuit is completed from the terminal on the opposite brushes of this commutator. A thick secondary circuit wire is connected to the terminal of the brushes on the commutator of the dynamo, and is coiled in series between the coils of primary wire and in the same direction round both the lower field magnets of the generator and motor. It is also coiled in series round the upper field magnets of the same over the coils of the primary wire and then passes to the translating devices in the consumption circuit. The main constant current passes through the few series coils of wire on the motor field magnets and the separate exciting coils on the generator field magnets, and thence through the terminals of the brushes on the motor armature and back again to the main supply circuit. The number of turns of wire in this motor circuit is just sufficient to maintain a given speed on the motor shaft with the minimum secondary current; and the number of turns of wire in the separate exciting coils on the generator field magnets is just sufficient to maintain a constant given electromotive force in the secondary circuit. The secondary circuit passes from the generator armature through the series coils of thick wire on the generator and the separate exciting coils of the motor, and thence through the translating device and back to the other terminal on the dynamo armature. The inventors make one claim for the method of winding, connecting, and exciting the two fields, as described.—No. 3225. March 2nd, 1887. 8*d.*

COMBINED ENGINES AND DYNAMOS.—*C. D. Abel, London. (Siemens & Halske, Berlin.)*—In the arrangements hitherto employed for driving dynamos directly from motor engines, the dynamos have always been constructed complete in themselves, and the axis of the revolving armature has been placed in line with the engine shaft and coupled to it by a rigid or flexible coupling. This arrangement necessitates the placing in line of the two shafts with numerous bearings, and any want of accuracy in adjustment leads to detrimental action as well as to an increase in the cost of installation. The object of the present invention is to obviate these defects. The dynamo is constructed in such a manner that some parts of it form part of the motor engine. The framing carrying the field magnets is fixed to a convenient part of the framing of the engine, and the revolving armature is mounted on an overhanging end of the engine shaft in the same way that the fly wheels and pulleys

are mounted in other work. The commutator brushes are carried by a bracket fixed either to the framing of the field magnets or to the engine frame. This invention may be carried into effect in combination with machines of various types. In the accompanying diagram the engine is coupled with a dynamo which was described in Patent No. 1738 of 1887. The internal field magnets A are fixed to the framing B of the motor engine, while the armature C is carried by the shaft D of the engine, and the commutator brushes E by a bracket F fixed on the engine frame. The inventors make two claims for the combination of a dynamo with a motor engine in such a manner that the revolving armature is carried by the engine shaft while the field magnets are carried directly or indirectly by the framing of the engine.—No. 4546. March 26th, 1887. 8*d.*

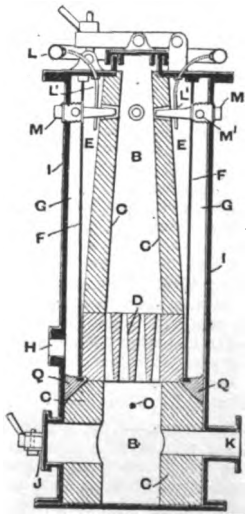
CHEMISTRY.



ELECTRO-DEPOSITION OF COBALT.—*S. P. Thompson, London.*—The solution used in the deposition of cobalt consists of the sulphate or chloride, or of the double sulphate or chloride of cobalt and ammonium, to which has been added either sulphate or chloride or other salt of magnesium. The anodes may be either carbon or cobalt, but preferably the latter. The best current density is from 1 ampère to 4 ampères per square foot of depositing surface; but a somewhat stronger current may be used at the beginning of the action, in order to secure a more rapid striking of the film on the surface. The pieces to receive the deposit should be scrupulously cleansed, and prepared in the same way as is usual in the deposit of nickel. The inventor makes two claims for the employment of magnesium salts in the deposition of cobalt.—No. 4472. March 25th, 1887. 6*d.*

SEPARATING PRECIOUS METALS FROM ORE.—*C. E. Tripler, New York.*—This apparatus is designed for extracting the metal by an improved process of amalgamation. The crushed ore is fed in the usual way from a hopper into a broad vertical tube. At a point near the upper end of this tube the vapour of mercury enters from a specially constructed retort. The quantity of vapour supplied is controlled and regulated by a tap, and a gauge is provided for ascertaining the amount used. The powdered ore in falling down the vertical tube becomes mixed with the mercury, and the resulting mass is afterwards led into a vessel which has a finely perforated bottom. A series of vibrating bars stir the liquid, and cause a more intimate mixture of the mercury and the ore. In a lower vessel the mixture passes over several amalgamating plates, and then the process is partly repeated by sending the material through a second perforated vessel and over another series of plates. The resulting amalgam is drawn off at the conclusion of each process into one of several collecting troughs. The inventor makes seven claims for this apparatus.—No. 16027. November 22nd, 1887. 8*d.*

MISCELLANEOUS.

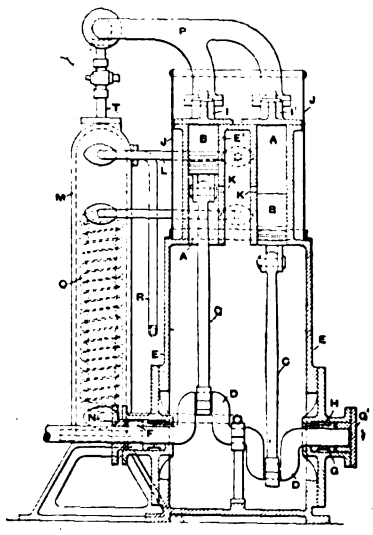


CEMENT.—*G. F. H. Clark & R. I. Clark, London.*—This cement is intended for fastening wood, linoleum, or other covering to iron or steel decks, or to wood flooring. The following ingredients together constitute the composition of this cement: fusel oil, amber, shellac, pigments, and rubber. In the process of making the cement the fusel oil is heated to a temperature of about 150°F., and the amber or other fossil gum in the form of powder is added gradually during the continued stirring of the solvent. The shellac and rubber are then dissolved, and finally the pigments. It is sometimes advantageous to add a small quantity of boiled linseed oil immediately after the solution of the amber. This product, in addition to its use as above described, may be also employed for treating felt so as to render it hard and water proof. One claim is made.—No. 5152. April 6th, 1887. 6*d.*

REGENERATIVE GAS FURNACE.—*D. Rylands & R. Potter, Barnsley.*—The annexed figure represents a sectional plan of the improved furnace as specially applied to the manufacture of glass. The chief compartments are those for melting, shown at N, and for working out, shown at A. The spaces F which lie between the two different compartments are made wide, so that the air can approach them. The free contact of the atmosphere with the walls of the furnace preserves them for a longer time. The sides E, the ends B, and the stop pieces in the walls are made of fire bricks, perforated with holes G running horizontally. A forced draught of air enters through the openings I J, blows

through the perforations, and leaves the walls E and B at the holes H K M. The stop pieces previously mentioned extend across the passages connecting A and N, and the perforations G run through them. The escaping blast is led to the air regenerators in the usual way. The blast may be arranged to pass through the blocks which constitute the working out ends C, in which case the air enters at J, and is made to pass through the blocks in C, and then escape at K. The furnace may be either fed from the crown of the melting portion N, or over suitable holes made in the sides E. The inventors make four claims for this improved furnace.—No. 2920. February 25th, 1887. 8*d.*

MANUFACTURE OF GAS FOR GAS ENGINES.—*F. Windham, London.*—Improvements are here introduced into the construction of gas generators, in which an incandescent grate or filter and combustion chamber are employed as described in Patent No. 3697 of 1886, granted to the same patentee. The accompanying figure represents a vertical section of the producer. Liquid hydrocarbon is introduced into this apparatus, and the heat of its own combustion serves to vaporise it and make it ready for use in the gas engine. The combustion chamber is indicated by the letter B; its walls C are made of fire brick, and a grate D is situated at its lower end. The vaporising chamber E has a surrounding wall F of iron, and an exterior chamber G is formed between the outside case I and the wall F. The air used in combustion is heated and regenerated in this chamber G, into which it is admitted through the opening H. A cleaning door is fixed at J and a delivery pipe at K. The petroleum is led from the main L through the pipes L^1 into the vaporising



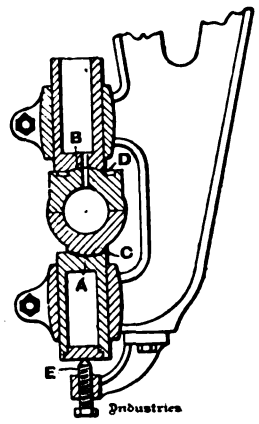
chamber E, and the heated air from G passes through the holes M^1 in the nozzles M into the combustion chamber. A certain amount of water is admitted to the space below the filter D through the opening O. In order to start the producer a fire is lit in the chamber B and the doors are closed; a supply of air is delivered at H and passes through M. The vaporised fuel which has been admitted into E passes through the recess in the wall C, and meets the stream of air issuing from the nozzles and immediately fires. The walls C and the filter D rapidly become incandescent, and the fire on D is allowed to burn out gradually. The gases resulting from the combustion are delivered through K under pressure. The water admitted through O also vaporises as the gases proceed past it, and the resulting steam mixes with the gases on their progress to the engine. The inventor makes six claims for the combination of evaporating chamber and the

Digitized by Google

mixing nozzles, for the use of the air heating chamber G, for the introduction of the jet of water through O, and for the combination of the incandescent grate and walls of the chamber with the foregoing appliances.—No. 1132. January 25th, 1887. 8*d.*

Refrigerating Apparatus.—*H. J. West, London.*—This invention relates to that class of ice making and refrigerating machines in which the cooling effect is produced by the alternate compression and expansion of a liquefiable gas, such as ammonia. The particular object in view in the construction of this machine is the removal of the heat of compression. The arrangements and plant will be understood by reference to the accompanying diagram, which represents a sectional elevation of a pair of compression pumps. The pumps A are enclosed, together with the cranks and shaft, in the air tight box E. One end of the crank shaft revolves in the bearing G, which is air tight, and provided with the channels H for lubricating purposes, while the other end passes through a stuffing box, and is connected with the outside driving gear. The delivery and suction valve boxes I I¹ are placed on the upper ends of the working cylinders, and both valve boxes and cylinders are surrounded by the jacket J, in which cooling water circulates. The upward prolongation E¹ of the case E is connected with the interior of the cylinders A by the passages K, and also with the vessel M, by means of the pipe L. The lower part of M

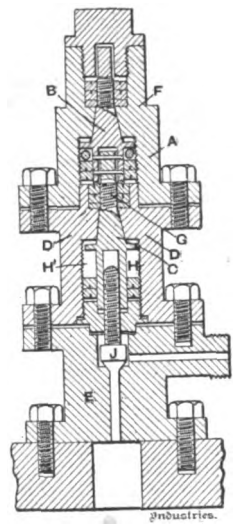
communicates with the lower part of E through the pipe N. The vessel M contains a coil O, through which cold water circulates. A lubricating liquid not attacked by ammonia occupies the space within the vessel M to a level slightly above the passages K, and the working parts of the pumps are also immersed in lubricating liquid. The liquid is cooled in the vessel M and falls to the bottom, whence it passes through N into the bottom of the case E. The lubricating liquid, being above the level of L, enters the cylinders A alternately, and is forced up with the compressed gas into the delivery pipe P. The object gained by this action is the cooling effect on the compressed gas, and the complete prevention of leakage of the gas. The oil falls down the pipe T into the vessel M, and thus returns to its old position. The cooling effect of the vessel J and coil O causes the oil to give up the heat abstracted from the gas. The inventor makes three claims for the application to machines in which the refrigerating effect is produced by alternate compression and expansion, of the means of cooling the lubricating material which has been heated by the compression of the gas.—No. 3964. March 16th, 1887. 8*d.*



Grinding the Rollers of Paper Machines.—*I. Gallowitsch, Vienna, and W. Seel, Warsaw.*—The cylinders or rollers are rotated in their frames in the same direction and in contact with each other, but with different circumferential velocities, and oil and emery are applied to them. The appliances for imparting the desired rotation to the cylinders consist of a shaft carrying two pulleys of different diameters, and two other pulleys of equal diameter keyed upon the ends of the opposite journals of the cylinders. The shaft is supported in bearings mounted upon pieces of wood fastened to the frames by bolts. The pulley on the journal of the bottom roller is connected with one of the pulleys on the shaft; while the pulley on the journal of the top roller is connected with the other pulley on the shaft by means of belts. The different speeds of the cylinders are thus obtained. The inventors make one claim for this method of grinding the rollers.—No. 8645. June 15th, 1887. 8*d.*

Button Making Machines.—*J. C. Schott, Providence, Rhode Island.*—This invention relates to a machine for making the common cloth buttons which are composed of front and back parts. A die is provided, which is in part expansible, so as to compensate for the different thicknesses of cloth, and to relieve the cloth from the damaging strain. The button parts are forced into the expansible die or ring to be united. The supporting and operating mechanism of the reciprocating plunger which drives the punch is also improved by a specially constructed swinging yoke, and by the use of a cam lever for engaging the head of the plunger. Two vertical posts are mounted on the base plate, and one of them is formed with a recessed head. The swinging yoke is pivoted at one end to the head of one of the posts, and its other end locks with its free end in the recess of the other post. A sleeve depends from the yoke, and the spring pressed plunger reciprocates in the sleeve. The inventor makes nine claims for the various parts and combinations.—No. 17531. December 20th, 1887. 8*d.*

Artificial Stone.—*L. Preussner, Berlin.*—The inventor mixes burnt magnesia and concentrated muriatic acid together in a proportion of from 1000 to 1500grm. of the acid to 1500grm. of the magnesia according to the amount of carbonic acid contained in the magnesia. This fluid paste is poured into hard india-rubber moulds to harden. The product resembles smooth and bright marble or enamel, and is not cracked by subsequent attacks of water and carbonic acid. The inventor makes one claim for this process.—No. 4689. March 29th, 1887. 4*d.*

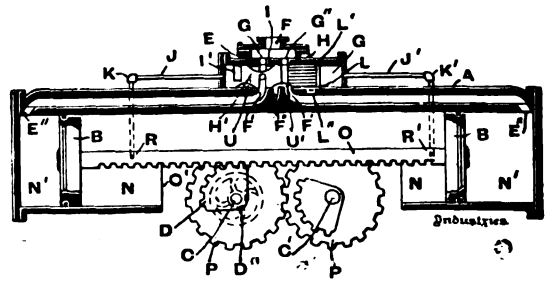


GERMAN PATENT ABSTRACTS.

Plummer Blocks.—*Escher Wyss & Co., Ravensberg.*—This invention relates to a modification of Sellers' plummer block. The adjustment in the vertical direction is effected by the

screw E, which lifts the spindles A B. The plummer block is connected to these spindles by two ball joints D and C, which are eccentrically arranged in A and B. By turning the spindles A and B, an adjustment in the horizontal direction is effected, while the plummer block retains the flexibility peculiar to Sellers' arrangement.—No. 41597. April 20th, 1887.

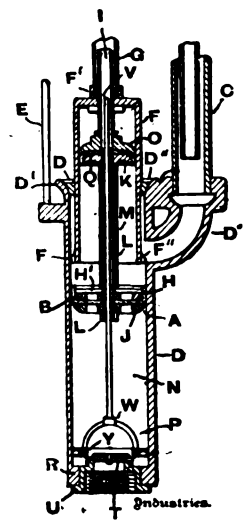
Liquid Carbonic Acid.—*Fleischer & Mühlich, Frankfurt-am-Main.*—This invention relates to a cut-off valve for liquid carbonic acid. J is the cut-off valve carefully fitted into the



valve casing E, and carrying a screw, the nut of which is cut into the piece C, which is provided with a ground cone fitted into D. H is a stuffing box arrangement, and G represents metallic packing. The same arrangement is made in A, B being the cone coupled to C, and F the metallic packing. By turning B, C is actuated and the cut-off valve J is opened or closed. Any gas escaping through C is arrested by B, thereby preventing waste.—No. 42114. January 18th, 1887.

UNITED STATES PATENT ABSTRACTS.

Electric Battery.—*H. Walter, Cincinnati.*—This battery is intended for open circuit work, and consists of a wide mouthed jar, which is hermetically sealed by its stopper. The negative electrode is composed of finely crushed carbon, which is packed into the space between the outer jar and an inner bag of suitable fabric. A piece of solid carbon is attached to the stopper, and carries the current to the wire in the usual way. The fine carbon is packed closely round the solid piece, in order to insure as great efficiency as possible. The positive electrode is contained within the cylindrical bag, and is provided at its lower end with a collar, which rests on the bottom of the jar. It is immaterial to this invention what energising fluid is made use of. The inventor makes three claims for this battery.—No. 378121, dated 21st February, 1888.



Refining Cotton Seed Oil.—*G. W. Scollay, New York.*—The object of this invention is to produce a refined cotton seed oil and a paint as the result of a single operation. A chloride of a metal not ultimately injurious to the oil as an article of food is mixed with the impure oil, and a small amount of alkali such as caustic soda is added to this mixture. After allowing these ingredients to intermingle thoroughly, the two products are separated from one another, and the refined oil is allowed to run off. It is found that the chloride of iron is the most efficient salt for employment in this process, as it accelerates the process of refining, and it does not injure the oil as a food substance. The inventor makes two claims for this improved process.—No. 378113, dated 21st February, 1888.

Steam Engine.—*F. A. Cresswell, Strongstown, Pennsylvania.*—This invention involves a new method of converting the reciprocating motion of the piston rod into the rotary motion of the driving shaft. The cylinder is double ended, and the two parts of the piston B are connected by a rod O, which has a toothed rack on its lower side. The middle part of the cylinder is left open, so as to allow the two similar segmental wheels D to gear with the rack on the piston rod. The wheels D are

mounted on the two similar shafts C C¹, as are also the two wheels P, which gear into one another. It will be seen by reference to the diagram that the two segments D revolve in opposite directions, and are only in gear alternately during the two different directions of motion of the rack. The shaft C¹ is only a short one, while C serves to transmit the energy to its destination. By this arrangement there are practically no dead points in the revolution of the shaft. A modification of the valve gear is also included in this invention. There are the usual steam ports F¹, exhaust port F², and steam chest G. The circular valve is provided with the steam space H¹, the exhaust ports U U¹, and the steam ports I¹ I². One end of the valve carries a toothed portion L¹, which gears with a straight rack shown in section at L². The seat of the valve has two openings G¹ G² in it for the admission of the steam from the chest F. The pipes J J¹ enter the valve chamber one at each end, and their other extremities are in the side of the cylinder as shown. When the piston B arrives at the end of its stroke, the steam is admitted by these pipes into the valve chamber, and the position of the valve is changed accordingly. A rotary motion is imparted to the valve by means of the rack L², so as to enable the steam to enter and exhaust through the recesses in the valve. The inventor makes five claims for the combination of the segment pieces in transmitting the motion, with the double ended cylinder, and with the valve gear.—No. 378041, dated 14th February, 1888.

Force Pump.—*B. C. Vanduzen, Ohio.*—The accompanying illustration shows the improvements introduced by this invention into the construction of a force pump. The lift out and drop valve P is made with an annular portion Y. Outer flanges and projections hold an annular spring which presses against the walls D. The circular legs and arch W are connected with

the annular portion as shown. The valve spindle of this drop valve moves in the raised valve seat I, which forms an annular sand chamber with the cylinder D. The rest of the pump is arranged according to previous designs. The inventor makes six claims for the drop valve as described, and for its raised seat I.—No. 377054, dated 31st January, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

GARVIE'S IMPROVED EXCAVATOR.

THE above illustration shows a simple form of excavator which has been designed by Mr. James Garvie, of 172, Fenchurch-street, London, and which is being manufactured by the Southgate Engineering Company, Limited, at their works at New Southgate. The principal feature in this excavator is the shape of the jib, and the readiness with which the excavator can be transformed into an ordinary steam locomotive crane or *vice versa*, by simply changing the jib. Thus any contractor who has work in hand, including only a small amount of excavation, need not go to the expense of purchasing any of the costly and somewhat cumbrous excavators or steam navvies, which have hitherto been the only machines in the market. It suffices in these cases to replace the ordinary jib of the steam crane by the special excavator jib shown in our illustration. By having these two jibs the contractor's efforts are greatly accelerated. When the machine is required to work as a steam crane the ordinary jib is used; but when excavating has to be done the ordinary jib is removed and replaced by the excavator jib, the change only occupying about an hour. Another advantage is that by this arrangement the ordinary gauge of rails may be used, whereas the "giant" excavators require a special gauge. The special excavator jib is formed by curved channel irons added to the under side of the beams, and secured to them by strong gusset plates, in the manner shown in the illustration. This lower part acts as a guide for the excavating bucket. In ordinary mechanical excavators the bucket is guided by a radiating arm attached to the machine, but in this excavator the bucket is fitted with four rollers which slide on the flanges of the curved guide. The lower part of the guide is horizontal and the upper part vertical. When working the excavator the bucket is lowered to the bottom, and the excavator brought up to the face of the cutting. The bucket is then lifted, and its lip cuts off a portion of the material operated upon, and by the time the bucket reaches the top it is filled. Attached to the bucket is a triangular frame, one angle being the pivoting angle of the bucket, the other carrying the chain block or sheave, and the third is provided with a pair of small guide rollers. The latter come into action when the bucket passes the curved part of the guide, running on the edges of it, and acting as a fulcrum for the bucket in turning from the horizontal to the vertical position.

When the bucket has reached its highest position it is relieved by the derrick chain, which draws the jib about 8in. back. The bucket is then turned round and emptied into waggons alongside or behind the excavator in the ordinary manner. The catch of the door is released by means of a cord pulled by the driver, the door being arranged to open at an angle of 60°, in which position it forms a shoot for the material discharged into the waggons. After discharging, the excavator is ready for another cut. The ordinary travelling motion of a locomotive crane is employed for bringing the excavator up to its work. The excavator is held down to the rails by screw jacks in the same manner as in the steam navvy, and balance weights are attached if required. It will be readily understood that the supplemental part of the jib, forming the guide, can be fixed to the existing jib of any ordinary locomotive steam crane. We are informed by the makers that an ordinary 4-ton locomotive crane, with the special gear attached to it, will excavate nearly as much earth as an ordinary steam navvy. It is not to be supposed that this excavator will take the place of the steam navvies now in use, which are very suitable for heavy excavations; but it should prove useful in cases where only small quantities of earth work have to be dealt with, and where economy in first cost is of importance.

GARVIE'S IMPROVED EXCAVATOR.

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

TEXTILE MACHINERY *(continued from page 183)*.—The machines used in the preparation of thread or doubled yarn form a special class. Before twisting the required number of strands together, it is usual to wind them from the cop or bobbins on which they are spun on to a bobbin resembling those used in a warping machine. This bobbin is driven by the frictional contact of its surface with a revolving drum, and the machine is fitted with a detector mechanism, which arrests the motion of the bobbin on the breakage or failure of any of the ends which are being wound on it. There were several machines of this class exhibited, which were chiefly constructed with a drop wire arrangement, similar to that described on the warping machine. The machine exhibited by Messrs. John Horrocks & Son, of Manchester, may be taken as a typical one. In this the yarn passes through an eye at the upper end of the detector wire, which it sustains during the operation of winding. The wires are fixed in an oscillating box, which has a small projection formed at the back. The bobbin is held in a frame, and is kept in contact with the drum by means of a prop, which presses against the projection in the oscillating box. When the detector wire falls owing to a failure of the yarn, its lower end comes in contact with a constantly revolving wiper, by which means the box is oscillated. The support of the bobbin being thus removed, the latter falls away from the drum, and its motion is immediately arrested by a brake. During recent years there has been a tendency to obviate the use of yarn bobbins, and in order to do this the traverse of the guide, by means of which the yarn is conveyed to the bobbin, had to be considerably accelerated. Instead, therefore, of laying the yarn in regular coils, the guide traverses the whole width of the bobbin at a very rapid rate. The spools so formed may be handled very roughly without any of the yarn ravelling off at the ends, and the saving in bobbins is very considerable. To attain this object a cam course was at first employed, by which the guide bar was traversed, Messrs. Dobson & Barlow, of Bolton, exhibiting a machine of this type. Mr. Samuel Brooks, of Manchester, also exhibited a machine in which guides were dispensed with, and the drums driving the bobbins were made in two parts, fixed on the shaft in such a manner as to leave a groove between them. This groove forms a cam course, and as the yarn passes round a rod, and through the groove to the bobbin, it receives the necessary traverse. It is, however, impossible in both these machines to effect a change in the lift of the bobbin—*i.e.*, the distance between the inside of the flanges—without changing the cams. Mr. Joseph Stubbs, of Manchester, exhibited a machine in which the guide rail derives its motion from a quadrant lever, the upper end of which is provided with a slot and the lower end with a segmental mangle wheel, by which the motion of the lever is reversed. The lever works on a stud suitably held, and has a reciprocating motion. A pin is passed through the slot in the quadrant lever, and also through a similar slot in a double ended lever, pivoted at its centre. The position of the pin may be altered to suit any lift, and is fastened in the required position by a nut. The upper end of the lever is attached in a suitable manner to the guide bar, which is thus actuated as required. By varying the speed of the pinion engaging with the mangle wheel, the speed of the traverse of the guide may be accelerated or diminished. After the yarn has been wound in the manner described, it is put on to the doubling machines, this being the general term applied to machines for twisting two or more ends of yarn together. The machines exhibited by Mr. S. Brooks and Messrs. Howard & Bullough illustrated two modes of doubling, known respectively as the Scotch and English systems. In the Scotch system the yarn is passed through a trough of water between a pair of brass rollers, while in the English system it is carried under a glass rod, which may or may not be immersed in water. The difference is very slight, and is probably attributable to the fact, that in Scotland most of the material pro-

Textile Machinery.

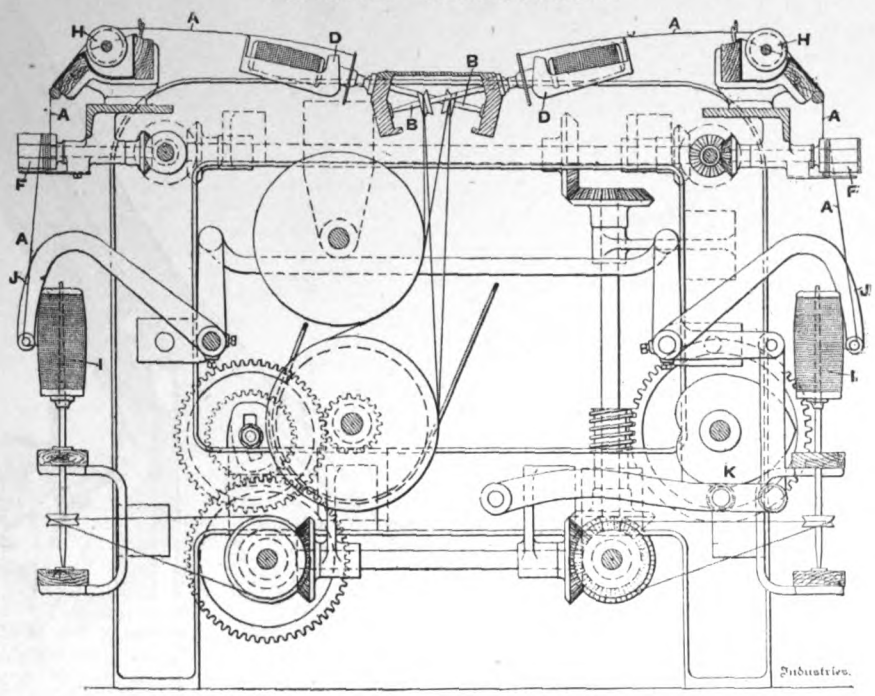

Fig. 63.

duced is intended for sewing thread, while in England it is used for weaving, lace, hosiery, and other purposes. The doubling machines are similar in every respect to the ring spinning frames previously described, except that the spindles are heavier, and the machines generally are stronger in construction.

One of the novelties of the late Exhibition was shown by Messrs. Shepherd & Ayrton, of Manchester, and was described as a twin twisting machine. The object of this machine is to put into the yarn or roving *two* twists for every revolution of the spindle, the accomplishment of which would enable more work to be obtained with a

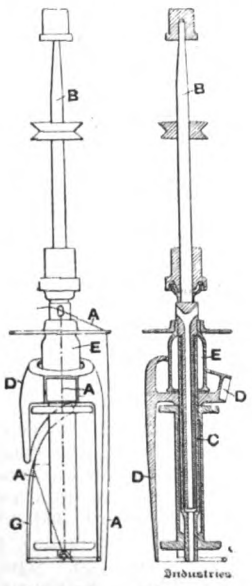

Fig. 64. Fig. 65.

slower speed of the spindles. The construction of the spindle is shown in side elevation and section in Figs. 64 and 65, and the general arrangement of the machine in Fig. 63. The spindle B is mounted as shown in Fig. 63, being borne by a collar and footstep, and revolved by a band passing over a warve in the usual way. A loose tube C, to which is attached a frame D, is mounted on the spinde, and D is so made that it is heavy at one side, and is consequently unable to rotate with the spindle. The latter is tubular, holes being formed at the end of the tube as shown in Fig. 65. A cup E with a steel disc attached is secured to B, and a bobbin is placed on the spindle upon which the untwisted yarn is wound. The course of the thread A is indicated in Fig. 64, and is as follows: Passing from the bobbin over the curved part G of the frame D, it travels along the outside of the latter until it reaches the end, when by means of a guide eye, placed as shown, it is taken up the tube in the spindle as indicated by the dotted line in Fig. 64. As soon as the end of the tube is reached the yarn issues by one of the holes shown, traverses over the edge of the disc, and thence over the roller H to a rotating roll F, which is hexagonal in form, and around which it is taken several times. From F the twisted thread is conducted over a guide fixed in the arm J to a bobbin I, mounted on a vertical spindle rotated by a band from a tin roller. The necessary traverse of the arm J is obtained from the cam K in the manner shown in Fig. 63. The rotation of the spindle gives one twist to the yarn as it is travelling from the bobbin to the tube in the spindle, so that when it reaches the holes by which it leaves the tube, one turn has been put in. Being held by the draw roller F at the delivery end, the revolution of B puts a second twist into the yarn after leaving the spindle and before going on the roller F. It is premature to do more than describe the mechanism at the present time, as the machine is still untried in actual work, or at any rate has not been tried on a scale which enables an opinion to be given of its actual merits, but it is sufficiently novel to be worth notice.

After thread is formed by twisting two ends of yarn it is, if intended for sewing cotton, "cabled"—that is, three strands of the double yarn are twisted together; and if for lace yarns it is "gassed," in this way having the "oose" or projecting fibres removed from its surface. After being produced as six-cord sewing cotton it is necessary to wind the thread on to small spools or reels ready for the market. The only machine shown for this purpose was Weild's patent, which is also made by Messrs. Shepherd & Ayrton. This machine is well known, but it may be of interest if the cycle of operations performed by it be described. The necessary changes are produced by the arrangement of suitable cams, and the machine is perhaps one of the most ingenious automatic machines extant. The frame shown had eight heads, that is to say, that number of reels were wound at one time. The heads are provided with two short spindles, one of which passes inside the spool, while the other grips it so as to turn it. The spools are placed in troughs, and assuming that the spindles are open, a spool falls forward on to a plate, which is in such a position that when the spindles close they accurately grip the spool. The thread is wound from bobbins held in a suitable creel, and is always fixed at its free end, so that the commencement of the rotation of the spool begins to wind on the thread. As soon as the spindles close on the spool they are automatically started and winding begins, the thread being passed over a steel guide which is fixed on a longitudinal rod. This rod is traversed at a speed accurately corresponding to the pitch of the thread when wound on the spool, and its length of traverse is increased in each direction at each stroke, so as to compensate for the greater length of the spool arising from the bevel given to it. As soon as the requisite length is wound the winding ceases, and a hooked knife descends and cuts a nick in one head of the spool, into which the end of the thread is subsequently drawn. The last named operation is effected by a hook which pulls down the thread into the nick and over a knife edge fixed for the purpose, thus cutting it and freeing the spool, which is then released by an automatic movement of the spindles. As the end is cut, it is held until a new spool is gripped, when the cycle of operations described is re-commenced. By this machine spools of any size of cotton, containing any defined number of yards, can be wound without necessitating on the part of the attendant any further care than that necessary to replenish the spools and bobbins.

The gassing frame is arranged with a number of gas burners of the Bunsen type fixed in swivels screwed into a pipe suitably placed, and which can be moved from under the yarn when a bobbin is raised for piecing. The bobbin is driven by frictional contact with a revolving drum, mounted on a longitudinal shaft suitably driven. At each side of the gas light is a stand, into which pins are fastened so as to be vertically adjustable. Brass grooved bowls revolve on these pins, the yarn on its passage from the bobbin in the creel to that on the drum being passed over these grooves several times. In order to obtain the best effect, the yarn is taken over the top of the first groove in the back runner, under that in the front runner, round the latter, under the second groove in the back bowl, and so on as many times as desired. It thus passes through the flame several times, and better gassing is obtained. The speed at which the yarn travels is carefully arranged to allow of the effective removal of any loose fibre, while preventing the yarn being burned down by the heat of the flame. The only machine of this class exhibited was shown by Mr. Joseph Stubbs, of Manchester.

(To be continued.)

ECONOMY TRIALS OF A NON-CONDENSING STEAM ENGINE.

At the ordinary meeting of the Institution of Civil Engineers, held on the 13th inst., a paper was read on the above subject by Mr. P. W. Willans, M.Inst.C.E., in which he described a series of economy trials, non-condensing, made with one of his "central valve" triple expansion engines, with one crank, having three cylinders in line. By removing one or both of the upper pistons, the engine could be easily changed into a compound, or into a single, engine at pleasure. Distinct groups of trials were thus carried out, under conditions very favourable to a satisfactory comparison of results. No jackets were used, and no addition had therefore to be made to the figures given for feed water consumption on that account. Most of the trials were conducted by the author; but check trials were made by Mr. MacFarlane Gray, Professor Kennedy, Mr. Druitt Halpin, Professor Unwin, and Mr. Wilson Hartnell. The work theoretically due from a given quantity of steam at a given pressure, exhausting into the atmosphere, was first considered. By a formula deduced from the $\phi\,\Phi$ diagram of Mr. MacFarlane Gray, which agreed in results with the less simple formulæ of Rankine and Clausius, the pounds weight of steam of various pressures required theoretically per i.h.p. hour were ascertained. A description was then given of the main series of trials, all at four hundred revolutions per minute, of the appliances used, and of the means taken to insure accuracy. A few of the results are embodied in the accompanying table. The missing quantity of feed water at cut-off, which, in the simple trials, rose from 11·7 per cent. at 40lb. absolute pressure to nearly 30 per cent. at 110lb.—and at 90lb. was 24·8 per cent.—was at 90lb. only 5 per cent. in the compound trials. In the latter, at 160lb., it increased to 17 per cent.; but on repeating the trial with triple expansion, it fell to 5·46 per cent., or to 4·43 per cent. in another trial not included in the table. On the other hand, from the greater loss in passages, &c., the compound engine must always give a smaller diagram, considered with reference to the steam present at cut-off, than a simple engine, and a triple a smaller diagram than a compound engine. Nevertheless, even at 80lb. absolute pressure, the compound engine had considerable advantage, not only from lessened initial condensation, but from smaller loss from clearances, and from reducing both the amount of leakage and the loss resulting from it. These gains became more apparent with increasing wear. The greater surface in a compound engine had not the injurious effect sometimes attributed to it, and the author showed how much less the theoretical diagram was reduced, by the two small areas taken out of it, in a compound engine than by the single large area abstracted in a simple engine. The trials completely confirmed the view that the compound engine owed its superiority to reduced range of temperature. At the unavoidably restricted pressures of the triple trials, the losses due to the new set of passages, &c., almost neutralised the saving in initial condensation; but with increased pressure, say to 200lb. absolute, there would evidently be considerable economy. The figures of these trials showed that the loss of pressure due to passages was far greater with high than with low pressure steam, and that pipes and passages should be proportioned with reference to the weight of steam passing, and not for a particular velocity merely. The author described a series of calorimetric tests upon a large scale (usually with over 2 tons of water), the results of which were stated to be very consistent. After comparing the rates of initial condensation in cases where the density of steam, the area of exposed surface, and the range of temperature were all variables, with other cases (1) where the density was constant, and (2) where the surface was constant, the author concluded that, at four hundred revolutions per minute, the amount of initial condensation depended chiefly on the range of temperature in the cylinder, and not upon the density of the steam, or upon the extent of surface; and that its cause was probably the alternate heating and cooling of a small body of water retained in the cylinder. The effect of water, intentionally introduced into the air cushion cylinder, corroborated the author's views, and he

showed how small a quantity of water retained in the cylinder would account for the effects observed. At lower speeds surface might have more influence. The favourable economical effect of high rotative speed, *per se*, was very apparent. In a trial with a compound engine, with 130lb. absolute pressure, the missing quantity, at cut-off, rose from 11·7 per cent. at 405 revolutions to 29·66 per cent. at 130 revolutions, the consumption of feed water increasing from 20·35lb. to 23·67lb. This saving of 14 per cent. was due solely to increase of speed. Similar trials had been made with a simple engine. In one simple trial at slow speed the missing quantity rose to 44·5 per cent. of the whole feed water. The author compared a series of compound trials, at different powers, with 130lb. absolute pressure, and various ratios of expansion, with a series giving approximately the same powers at a constant ratio of expansion, but with varying pressures, being practically a trial of automatic expansion against throttling. Starting with 40 i.h.p., 130lb. absolute pressure, four expansions, and a consumption of 20·75lb. of water, the plan of varying the expansion, as compared with throttling, showed a gain of about 7 per cent. at 30 i.h.p., but of a very small percentage when below half power. If the engine had an ordinary slide valve, the greater friction, added to irregular motion, would probably neutralise the saving; while if the engine were one in which initial condensation assumed more usual proportions, the gain would be probably on the side of variable pressure. Even as it was, the diagrams showed that the missing quantity became enormously large as the expansion increased. Judging only by the feed water accounted for by the indicator, the automatic engine appeared greatly the more economical; but actual measurement of the feed water disproved this. The position of the automatic engine was, however, relatively more favourable when simple than when compound. In conclusion, the author referred to a trial with a condensing engine, at 170lb. absolute pressure, in which the feed water used was 15·1lb., a result evidently capable of further improvement, and to an efficiency trial of a combined central valve engine and Siemens dynamo, made for the Admiralty, at various powers. At the highest power the ratio of external electrical h.p. to indicated h.p. in the engine was 82·3 per cent. Taking the thermo-dynamic efficiency of the engine at 80 per cent., that of the combined apparatus would be nearly 66 per cent.

IMPROVED COMMUNICATION BETWEEN BIRMINGHAM AND THE SEA

We have already, on page 257 of our last volume, drawn attention to a scheme for improving the Worcester and Birmingham Canal, and thereby enabling vessels of 250 tons burden to reach the Midland district. Since the inception of this project two others have been developed, one of which proposes to open up communication between Birmingham and London by an extension and alteration of existing waterways. These are the Grand Junction Canal, the Oxford, Warwick, and Napton Canal, and the Warwick and Birmingham Canal. Mr. Hickman, M.P., the chairman of the committee for improving the water communication between London and Birmingham, points out that these canals are fortunately independent of railway control, and he recommends (1) that the locks on the Grand Junction Canal should be made double, and those on the Oxford, Warwick, and Napton Canal, and the Warwick and Birmingham Canal should be increased to four times their present size—160ft. long by 14ft. 6in. wide—with not less than 7ft. of water over the sills instead of 4ft. 6in. as at present; (2) that the total number of locks should be reduced from one hundred and fifty-four to ninety by the substitution of deep or compound locks in place of the existing flights of shallow locks; (3) that the improved canal should have a minimum top width of 45ft., a minimum bottom width of 21ft., and a minimum depth of 8ft., with side walling on the towing path side extending to a depth of 3ft. below top water level in places where the canal will have a less top water width than 50ft., and where it is proposed to raise the level of the water above that of the existing canal; (4) that the passage way through and under numerous bridges should be widened, deepened, and heightened, and that the line of the canal should be improved by doing away with 132 awkward bends and by making forty-four deviations, which would lessen the distance now traversed by two miles. By these means would be rendered possible the passage of cargo carrying tugs drawing three ordinary canal boats, and carrying altogether 120 tons of cargo, and each of such fleets could pass at one lockage; or in place of this, two Thames barges carrying 140 tons, or one steamer carrying 140 tons, might pass the locks. The present canals have a carrying capacity of about 750,000 tons per annum, and it is estimated that the improved canal would have a capacity about 2½ times as great, *i.e.*, about 2,000,000 tons. A considerable reduction would be made in the time of transit—which is estimated at about fifteen hours. The cost of haulage would at the same time be reduced from about 3s. 8d. to about 1s. 10d. per ton. These reductions, in conjunction with the improved carrying capacity of the canal, would allow great relief to be given in the matter of tolls. It is estimated that Class A goods, which at present cost 15s. per ton by rail from London to Birmingham, or 12s. 6d. in 10-ton lots, would be carried on the canal for 6s. per ton, including collection in Birmingham and delivery alongside ship, in addition to haulage and tolls. The improvements would also probably result in a great extension of the South Staffordshire coal trade, since the rate for carriage to London would be about 4s., as against the present railway rate of 6s. 9d. per ton. The cost of the alterations is put down at about £1,250,000. It is proposed to acquire the existing canals either by payment of a sum down or by renting them at a charge based upon the present value and annual net income. The existing tolls would of course be lowered; it is proposed to reduce the rate on Class A goods from 3s. 2d. to 2s., and on coals and raw materials from Staffordshire to London to 1s. per ton, and from the Warwickshire coal field to 10d. per ton. These reductions would, it is estimated, involve a loss of about £7,500 per annum, while the extra cost of maintaining the larger and busier canal is placed at £12,500 per annum. The interest on £1,250,000 at 4 per cent. being added to this, it will be seen that a total of £70,000 per annum would be required to meet expenditure and pay a satisfactory dividend. For this extra amount the committee confidently look to the greatly increased traffic which would immediately begin to result. The report and surveys regarding this system were made by Mr. Martin, C.E., who has subsequently proposed a modification of the scheme. According to this, a new canal would be made which would commence by a junction with the Warwick and Birmingham Canal about eight miles from Birmingham, and proceed for about eleven miles in a south-easterly direction, making a junction with the Oxford Canal near Coventry. The last named would require enlarging as far as Brannston, where it would join the first considered improved route by a union with the Grand Junction Canal. This alternative route would involve an additional outlay of £300,000; but it would reduce the total number of locks to seventy-three, and would furthermore shorten the journey by three or four hours, thereby considerably decreasing the cost of transit. It would in addition directly connect the Warwickshire coal field to Birmingham, and reduce the cost of coals in that town by about 1s. per ton.

It may be taken for granted that some such scheme will before long be carried out, and the London route is the one for special reasons most likely to be adopted; firstly, because of the moderate cost of the proposed works; secondly, because so much of the present traffic goes to the Thames; and thirdly, on account of the regular and abundant supply of out and ingoing steam vessels with which the Midland district would be brought into direct connection. It is understood that the committee appointed by the Birmingham Corporation to consider the whole question of water communication, have determined to strongly recommend the adoption of this route, while a route *viâ* the Trent to Hull as an alternative has also been suggested.

THE PROTECTION OF INVENTIONS AND DESIGNS IN INDIA.

A Bill amending the law relating to inventions and designs has been published in the *Gazette of India*, together with the Report of the Select Committee to which the Bill was referred. Several important departures from the existing law and practice will follow upon the passing of the Bill, which it is contemplated will become law without alteration, and come into force on the 1st of July, 1888. The provisions of the Bill stipulate that the applicant for an exclusive privilege must furnish such drawings or photographs of the invention as may be required, and in exceptional cases a model. The application may be referred for inquiry and report to any person whom the Governor-General in Council may think fit. If this person is not in the employ of the Government, the applicant will have to pay such a fee as the Governor-General may determine, and this fee, or a sufficient sum to cover it, must be deposited by the applicant before the reference is made. In the event of the non-payment within the specified time of the renewal fees, which will come into force under the new law, an extension of the time up to three months may be obtained on payment of a fine, as provided by the British Act of 1883. No amelioration of the practice under which at least five copies of the specifications and drawings are required is provided, and it may possibly be ordered that an additional set of copies shall be filed. All applications will be numbered and dated consecutively on the date of application. A patent, or, as it is called in the new Bill, "an exclusive privilege," may be prolonged for a term not exceeding seven or, in exceptional cases, fourteen years. The Government is bound equally with a private individual not to use a protected invention without consent; but if terms are not arranged between the officers of the Government and the owner of the invention, any department in the Imperial service may use it on such terms as may be settled by the Governor in Council. When an English patent has been applied for, protection for the same invention may be had by the inventor if the Indian application is made within twelve months. In other cases, the privilege will be invalid if the invention has been published in India or in the United Kingdom, unless that publication is in fraud of the inventor, or results from the use by the inventor or his agent for a period of less than one year. The duration of the protected period for a registered design is five years. The fourth schedule to the Bill sets forth the fees payable in respect of an exclusive privilege. The fees on application are Rs.10; on filing the specification, Rs.30; before the expiration of the fourth, fifth, sixth, seventh, and eighth years respectively, Rs.50; at the end of each subsequent year up to the thirteenth, Rs.100.

TOBACCO CULTURE IN ENGLAND.

Those who are taking an interest in the cultivation of tobacco in England, a subject to which we have on former occasions directed the attention of our readers, are not likely to receive much encouragement in their efforts from a perusal of the reply which was given by the Chancellor of the Exchequer to a deputation from the British Tobacco Growers' Association, which recently waited upon him. As we have mentioned in our previous notice, in order that it might be tried whether the growing of tobacco in the United Kingdom may not be carried on for the purpose of utilising to a certain extent the prevailing agricultural depression, leave was given, under certain conditions, for the working of experiments, and the recent agricultural returns show that more than eighteen acres were planted with tobacco. The conditions, however, were too onerous to allow of an adequate return, and the object of the visit of the deputation to the Chancellor of the Exchequer was to ask that the Society they represented should be granted a license to grow and sell tobacco throughout the United Kingdom for a payment of £25 per acre per annum for five years, for the purpose of making experiments as to the cultivation, manufacture, and marketable value of British tobacco. Lord Walsingham informed the Chancellor of the Exchequer that on a piece of land he had grown the equivalent of 800lb. of tobacco to the acre, and he was of opinion that the weed could be successfully cultivated and prove an important outlet to surplus labour, provided a substantial reduction of taxation was granted. The Chancellor of the Exchequer, as in duty bound, has always a sharp look out for proposals which are likely to affect the revenue, and in the presence of the deputation he calculated that 800lb. of tobacco at 3s. meant £120 per acre, and to grant the request which was made to him would mean a sacrifice to the revenue of about £100 on every 800lb. grown in Britain. Widespread success in the cultivation of tobacco, with a duty of £25 per acre, would be a very serious matter for the revenue, which derived from the tax on imported tobacco in the financial year ending March, 1887, the large sum of £9,367,185. This was obtained by duties varying from

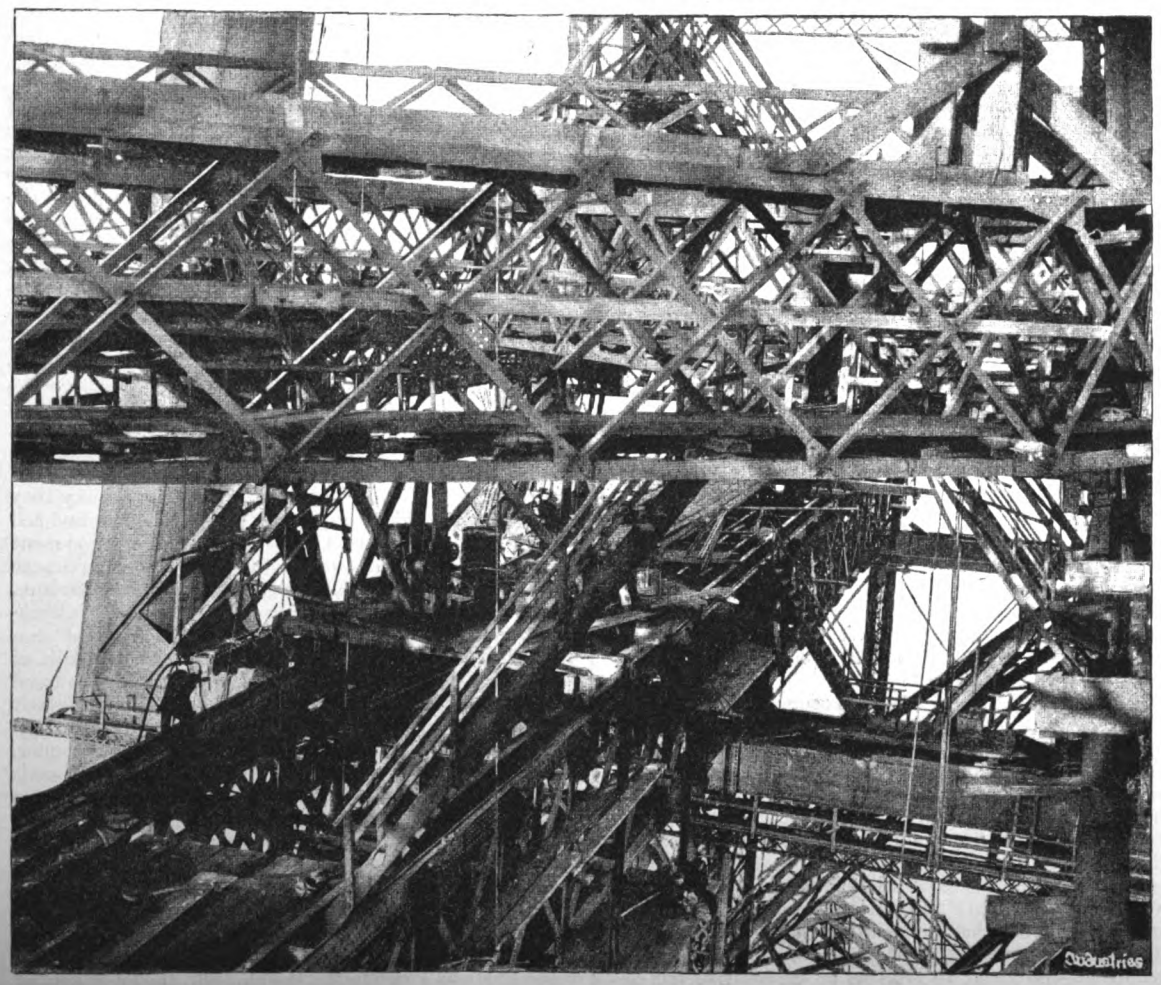

FIG. 2.—INTERNAL VIADUCT, WITH HORIZONTAL AND DIAGONAL BRACINGS.

3s. 6d. on unmanufactured to 4s. 10d. on manufactured tobacco, and 5s. 6d. on cigars. Mr. Goschen pointed out that if they were to have acreage duties in various parts of England, it would be extremely difficult to avoid very great risks, and he did not see how the difficulty could be got over, nor could he hold out any hope of a reduction of duty. Looking at the great importance of maintaining a sum which was equivalent to about 4d. in the pound on the Income Tax, which the duty on tobacco represented, he thought the deputation would feel that it was his duty to do nothing which would threaten the revenue. We sympathise with the opinions of the Chancellor of the Exchequer, and we feel that there are sundry breakfast table duties, amounting to about £5,000,000, to be got rid of before we can think of reducing the sum derived from a luxury like tobacco. We further confess that so long as we have a system of indirect taxation, it is difficult to see how the matter could be arranged, and few, we imagine, would be inclined to resort to a direct taxation of incomes, which would relieve luxuries of the greater part of their burdens, and press unduly on those who could not afford such luxuries.

THE FORTH BRIDGE.

As work at the Forth Bridge progresses, the magnitude of the undertaking becomes more and more impressively manifest. Cantilever bridges are not novelties; but the huge scale upon which this one is built brings into play difficulties which do not exist in smaller constructions on the same principle. At every point interesting questions arise, not only in matters of detail, but even in the general system of construction. Thus, before the erection of the cantilever bays was begun, the question arose as to the desirability of carrying up to the whole height of the bays a horizontal lifting platform, similar but lighter than that used in the construction of the main piers. It was decided to adopt the lifting platform principle up to about one-half the height of the cantilever bays, and to construct the top member, with the relative ties, struts, and bracings, by an overhang from above. The top member, which consists of steel lattice girders, is therefore built out from the top junction without support for about 160ft., or half the length of the first bay. At this point it meets the first vertical tie, which is temporarily employed as a support until the other half of the bay is built, when the top member will be united to the bottom member by diagonal struts and ties. The building outwards and downwards of so enormous masses of metal involves careful adjustment of weights and strains. Our illustration (Fig. 5) on page 296 is a view of the Fife pier, and here the system of overhang is displayed to advantage. A comparison of our view of this pier, which we gave some time ago (see *Industries*, Vol. III., page 450), with our present illustration, will enable our readers to observe the progress made in the construction. This pier is rather further advanced than the other ones, and possesses the further advantage from an illustrative standpoint that it offers more eligible points of view than either the Inchgarvie or South Queensferry Pier.

The two steel girders of which the top member is composed are permanently connected by means of horizontal diagonal bracings; but in addition they are temporarily connected by a broad platform upon which a crane runs. This crane has two jibs, of which one is used for carrying the riveting machines, and the other for hoisting and lowering material. This crane in effect builds its own foundation as it advances. Our illustration (Fig. 5) shows the main pier practically completed, and the construction of the cantilever bays carried on to the point at which the second diagonal strut branches upwards from the bottom member. The top member is carried out to the point at which the first vertical tie will meet it. The diagonal ties are shown stretching downwards from the top junction, each of them having its constructive platform and joining the diagonal struts, which are built upwards from below, and intersect the diagonal ties at a point somewhat above the level of the internal viaduct. The internal viaduct is also observable in our illustration (Fig. 5) stretching across the pier, having been erected on either side to a point beyond and below the intersection of strut one and tie one.

The internal viaduct is also built in the same manner. It is provided at either end with a two-jibbed crane, which raises material on one side from a jetty, and on the other from barges in the Forth. The crane travels along the viaduct as the work progresses, building its own foundation as it advances. The chief feature in the method of construction, viz., that the structure is its own scaffolding, each part carrying with it as it is put in position the means of further advance, is well illustrated by these examples. The riveting rings, painters' stagings, and temporary ties will be recognised among other instructive details. The method of overhang, the adoption of which was fortunately impossible in the earlier stages of construction, might have been attended with great danger.

A mass of steel weighing hundreds of tons, and projected from a point 360ft. high, like a gigantic arm, outwards over an arm of the sea, strikes the imagination so much that it might well have been impossible to find workmen reckless enough to risk their lives in carrying out such a work. The gradual progress of the work from water level upwards has so far trained the vast number of workmen employed on the bridge to work at high altitudes, that they have become accustomed to the nature of the work, and do not shrink from risks which seem to them enormous only at a distance, and which diminish when approached. Thus the system of overhang, fearful as it is to the uninitiated, has been so far accomplished with very few accidents. When the bottom member and top member approach each other, the diagonal ties and struts will unite them together. These diagonal ties, built downwards from above, as described (see Fig. 5), will be converted into ties proper by bringing hydraulic pressure to bear upon them, so as to compensate for the slight depression inevitably due to the length and weight of the top and bottom members. The required tension will be easily obtained by cutting the tie when complete and drawing the ends together by means of hydraulic pressure. Within the past few days, and since our views were taken, the first ties of the northernmost bays on both north and south main piers have thus been connected to the top and bottom members in these bays. During the progress of the structure, the rivets at all the junctions are only partially inserted, and screw bolts are largely used for the purpose of enabling the correction of any depression without causing an excessive strain in the structure as a whole. We have been favoured by the engineers of the bridge—Sir John Fowler and Mr. Benjamin Baker—with the accompanying illustrations of details, which are exceedingly interesting, though the maze of angle irons, girders, and columns is apt to render them confusing at a first glance. If studied, however, with reference to the larger views, which illustrate the positions of these details in the structure, they will become more intelligible.

Intersection of Diagonal Tubes.—Fig. 1 represents the intersection of the diagonal tubes of the main pier at Queen's Ferry, west side. The point of intersection in the main piers will be found in Fig. 5, and the details of them are the same both in the north and in the south piers. The point of intersection in the diagonal tubes is also the junction of the horizontal bracings.

Internal Viaduct, with Horizontal and Diagonal Bracings.—The view shown in Fig. 2, though at first sight a confused mass of girders, will be readily understood by a little study. It represents the internal viaduct at the point where it passes through the main pier on the Queensferry or south side of the Forth. The view is taken from a point above the viaduct in bay one, and at about the level of the horizontal diagonal bracing shown in the illustration. The viaduct, which is intended for a double line of rails, consists of four lattice girders resting upon strong plate girders connected to the main columns of the piers, and to the struts of the cantilever bays. The tube to the left is the south-west tube of the Queensferry main pier. The girder passing across the upper portion of the illustration is the horizontal diagonal bracing of the first tie. It is connected at the extreme right to the south-eastern tube of the pier. The diagonal girders which brace the sides of the structure together beneath the level of the viaduct are seen crossing each other, and the vertical columns which aid in the support of the horizontal plate girders upon which the viaduct rests are seen springing from their intersections. The photograph from which Fig. 5 was reproduced was taken by Mr. Philip Phillips; the others (Figs. 1, 2, 3, and 4) were taken by Mr. E. G. Carey, Assoc.M.Inst.C.E. The bridge, in spite of the inclemency of the weather during a great part of the winter, has made extremely rapid progress.

Crossing of Tie One and Strut One, and Temporary Vertical Column.—Fig. 3 shows the method of passing the strut tube through the open girder which forms the tie. The vertical column, which is temporarily used to support the top member, will, in the permanent structure, not be carried further than this crossing, as it will become unnecessary for the support of the top member as soon as the diagonal struts and ties are in position.

Junction of Strut Two and Tie One with Bottom Member.—Fig. 4 represents the junction of strut two, a steel tube of 8ft. diam., and tie one, an open lattice girder, with the bottom member at the N.E. corner of the Queensferry pier. The first ten plates of the strut are alone in position, and a short length has yet to be added to the tie, projecting downwards, to effect a connection between the bottom and top member. As has been explained before, the top member has been built downwards by means of a moving platform, which is fixed at the lowest end, and construction carried on simultaneously a few feet below and a few feet above the platform. The crane, which moves along the tube of the lower member, erects its own travelling way, always in advance of itself, in the shape of the permanent structure.

THE FORTH BRIDGE.
